Neovasculogenesis is a process dependent on the activity of various cytokines such as VEGF, bFGF, angiopoietins and SDF-1 (Parsons-Wingerter et al., 2000 Visconti et al., 2002). The mechanisms by which they orchestrate neovascularization are still disputed. It is known that a gradient of SDF-1 is formed at an ischemic site, which causes the mobilization of bone marrow cells expressing CXCR4 and the receptor-ligand interaction triggers signaling cascades involved in the growth, proliferation and cell survival (Ganju et al. 1998, Petit et al., 2007, Roland et al., 2003). In this context, we sought further to evaluate the expression profile of SDF-1 by early EPC and we investigated whether paracrine role of these cells in neovasculogenesis is mediated by SDF-1 (Chapter II.5.). Also, given that SDF-1/CXCR4 interaction is exploited increasingly more to stem cell therapy after MI (Zhang et al., 2007), we proposed to study the function of CXCR4 in cardiac remodeling after MI in genetically modified mice ($CXCR4^{+/-}$) in order to identify possible adverse effects that pharmacological compounds may have (Chapter II.6.). The results showed that early EPCs secrete increased amounts of SDF-1 and are able to bind SDF-1 to their surface, thus creating a local gradient that may attract from circulation stem/progenitor cells $CXCR4^{+}$ with angio-/vasculogen potential. On the other hand, *in vivo* studies on transgenic mice demonstrate that CXCR4 has a double-edged effect on cardiac remodeling after MI. Thus, on one hand, mice $CXCR4^{+/-}$ presented smaller and more stable scars after IM, this associated with rather regenerator monocytic response and better adaptation of cardiac myocytes to hypoxic stress. On the other hand, early EPC function is impaired in transgenic mice, reduced myocardium neovascularization and the reduction of coronary flow recovery, being responsible for the lack of improvement of ventricular function. Thus, extrapolating these results to inhibit CXCR4 in human system should be done with caution.

In conclusion, the data contained in this thesis demonstrates that:

- Early and late EPC can be obtained from peripheral blood and cord blood

- Endothelial potential of stem/progenitor mesenchymal cells is limited, but this cell type can be exploited to stimulate neovascularization based on their paracrine properties

- Factors released *in vitro* by early EPC are able to significantly stimulate the formation of new vessels by late EPC, early EPC transplantation is not mandatory to achieve this effect.

- Early EPC maintains their paracrine properties under hypoxia and VEGF is not essential for their angiogenic effect.

- Paracrine factors secreted by MSC supports some of the processes involved in angiogenesis (support chemotaxis and adherence of EC, but not proliferation) and have beneficial effects on ischemic cardiomyocytes, and these properties are maintained when MSC are subject to hypoxia.

- *In vitro* effects of early EPC are complementary to those induced by MSC, stimulating proliferation, but not EC adhesion. Both of these effects can be induced simultaneously by combining the conditioned medium (obtained from the EPC and MSC). Thus, the combination of these two cell populations or factors secreted by them could be a successful strategy for inducing therapeutic angiogenesis.

- Early EPC secrete increased amounts of SDF-1 and are able to bind SDF-1 to their surface, thus creating a local gradient that can attract circulating stem/progenitor cells $CXCR4^{+}$ with angio-/vasculogenic potential to an ischemic site.

- CXCR4 presents a double-edged effect on myocardial remodeling after MI, its low expression causing the formation of smaller and more stable scars, but affecting cardiac neovascularization and recovery of ventricular function.

Based on the original results obtained during the doctoral internship new strategies can be envisaged that might optimize the therapy for revascularization of an ischemic territory. These preclinical data are likely to be strengthened in future clinical trials.

RÉSUMÉ

Dans le contexte actuel dans lequel les maladies cardiovasculaires sont la première cause de mortalité, l'élucidation des mécanismes qui sous-tendent le processus de formation de nouveaux vaisseaux sanguins chez l'adulte (néovascularisation), préoccupe fortement la communauté scientifique. Bien que de nombreuses études expérimentales et des essais cliniques visant les cellules souches / progénitrices pour induire l'angiogenèse et la myogenèse ont montré des résultats encourageants (Gersh et al, 2009, Heil et Schaper, 2004;. Lipinski et al, 2007, Mitsos et al.. 2012), les mécanismes par lesquels les différentes populations de cellules souches / progénitrices aident à améliorer la fonction cardiaque post-AVC sont encore mal connues (Gersh et al., 2009). Une meilleure compréhension de ces mécanismes pourrait accroître l'efficacité des thérapies cellulaires. Également, compte tenu de l'environnement ischémique dans lequel les cellules souches arrivent après la

transplantation au niveau de l'infarctus du myocarde, il est primordial de comprendre les propriétés paracrines des cellules souches dans des conditions hypoxiques. Cela permettrait de concevoir des stratégies thérapeutiques adaptées à chaque patient, afin de surmonter les obstacles éventuels causés par les caractéristiques pathologiques. L'optimisation de la stratégie pourrait être faite par le choix des populations cellulaires les plus appropriées ou des combinaisons des populations ou en utilisant uniquement des facteurs sécrétés par eux-mêmes, mais aussi par le choix de la voie d'administration et du moment de la transplantation par rapport à un accident vasculaire aigu. En outre, les cellules à injecter peuvent être préconditionnées par la stimulation avec diverses cytokines ou un bloc ou sur-expression du récepteur (Herrmann et al. 2011, Richardson et al., 2013).

Dans ce contexte, cette thèse met en évidence les populations de cellules souches / progénitrices qui présentent un potentiel angio-/vasculogène et aussi certains des mécanismes par lesquels ils contribuent à la néovascularisation des tissus ischémiques. En outre, en visant principalement l'amélioration de la fonction du myocarde après un infarctus, on a suivi non seulement l'effet bénéfique de ces types de cellules sur la néovascularisation, mais aussi la protection des myocytes cardiaques exposés à un stress hypoxique. Aussi, par l'intermède des études effectuées, on a examiné également la contribution des divers facteurs paracrines au potentiel thérapeutique des cellules souches / progénitrices et aussi le changement d'expression et des propriétés paracrines dans un milieu hypoxique. Dans la dernière partie, la contribution de l'axe SDF-1/CXCR4 au rôle paracrine des cellules progénitrices et la fonction de CXCR4 dans le remodelage cardiaque après un infarctus du myocarde ont été évaluées.

La thèse, qui couvre 233 pages, est divisée en deux parties comprenant 143 figures (dont 105 se trouvent dans la deuxième partie), 7 tables (dans la seconde partie) et 290 citations.

Dans la première partie, -L'état actuel des connaissances-, organisée en 6 chapitres, l'auteur a presenté d'abord les options thérapeutiques disponibles, soulignant ainsi la nécessité de développer de nouvelles stratégies thérapeutiques (Chapitre I.1.). Ensuite, après une brève description de la structure des vaisseaux sanguins (Chapitre I.2.), on a fait une incursion dans les mécanismes physiologiques de la néovascularisation (Chapitre I.3.), en définissant les termes vasculo-, angio- et arteriogenèse. Les étapes de l'angiogenèse (réorganisation de la membrane basale, de la matrice extracellulaire et du cytosquelette lors de la migration des

cellules endothéliales, la maturation et la stabilisation du vaisseau) sont décrites en détail. Le quatrième chapitre (Chapitre I.4.) présente plusieurs modèles sur lesquels peut être étudiée expérimentalement la formation de vaisseaux, et dans l'avant-dernier chapitre (Chapitre I.5.), les principaux facteurs qui modulent la néovascularisation sont présentés. Le dernier chapitre (Chapitre I.6) est consacré à la description des différentes stratégies qui peuvent être utilisées pour l'induction de la néovascularisation, en passant d'abord en revue les principaux types de cellules souches et leurs propriétés générales et ensuite en détaillant les caractéristiques des deux types de cellules impliquées dans la néovascularisation : des cellules progénitrices endothéliales (EPC) et les cellules souches mésenchymateuses (CSM). Enfin, l'auteur a synthétisé l'état actuel des études expérimentales et cliniques, en décrivant leur succès et leurs limites.

Dans la deuxième partie de la thèse, -Les contributions originales-, les études ont été organisées en six chapitres. Les premières études ont été axées sur l'identification du potentiel endothélial de certaines populations de cellules souches / progénitrices (**Chapitre II.1.**). Les résultats ont montré que les deux types d'EPC décrits dans la littérature (précoces et tardives), aussi que des CSM, peuvent être obtenus à partir de quelques sources tissulaires comme le sang périphérique, le sang du cordon ombilical, la gelée de Wharton et la moelle osseuse. Le potentiel endothélial des CSM est réduit, mais le phénotype sécrétoire a toujours suggéré de suivre leurs propriétés paracrines afin de stimuler la néovascularisation.

De nombreuses études appuient la contribution des EPC précoces et tardives au processus de néovascularisation par des mécanismes distincts: les premières ayant un rôle paracrine, tandis que les EPC tardives, ayant un potentiel de prolifération élevé, ont la possibilité de s'intégrer dans les vaisseaux en formation (Asahara et al, 1997;. Hur et al. 2004 Sieveking et al., 2008). Il est également reconnu que la formation de nouveaux vaisseaux peut être modulée en utilisant une combinaison de facteurs angiogéniques. Le processus peut être amplifié lorsque ces facteurs sont administrés de manière séquentielle (Freeman et Cohen 2009, Hao et al., 2007). D'autre part, une étude qui a examiné l'effet de la co-administration des EPC précoces et tardives sur la néovascularisation en utilisant un modèle in vivo d'ischémie fémorale, a montré que les deux types de cellules ont un effet synergique (Yoon et al., 2005). Ces données soulèvent la question si l'effet bénéfique obtenu dépend de facteurs libérés par les EPC précoces, en raison d'une réponse dynamique de ces cellules aux conditions rencontrées in vivo. Pour répondre à cette question, en utilisant deux

modèles in vivo, nous avons cherché si les facteurs sécrétés in vitro au début par les EPC précoces peuvent améliorer la néovascularisation induite par les EPC tardives (**Chapitre II.2.**).

Les résultats montrent qu'en présence de facteurs sécrétés par les EPC précoces in vitro, les EPC tardives incluses dans un morceau de Matrigel et transplantées de manière sous-cutanée chez la souris peuvent être organisées dans les structures vasculaires qui ont la capacité de fusionner avec le réseau vasculaire de l'organisme hôte. Également, la transplantation des EPC tardives dans le muscle ischémique en présence des facteurs sécrétés par les EPC précoces augmente significativement la perfusion tissulaire; un effet qui n'est pas obtenu à un niveau similaire lorsque les EPC tardives ou les facteurs sécrétés par les EPC précoces sont administrés séparément. Ainsi, nous pouvons conclure que les facteurs libérés in vitro par les EPC précoces sont capables de stimuler de manière significative la formation de nouveaux vaisseaux par les EPC tardives, et l'administration des EPC précoces n'est pas nécessaire pour obtenir cet effet positif.

L'identification des facteurs appartenant au milieu conditionné responsables de l'effet bénéfique permettra la formulation d'un composé thérapeutique qui peut être produit à grande échelle et qui peut être administré à un site ischémique, conjointement avec des EPC tardives, afin d'améliorer la perfusion tissulaire. Ainsi, à partir des résultats des études in vivo, nous avons cherché une description plus détaillée des facteurs paracrines responsables de l'effet bénéfique des EPC précoces (**Chapitre II.3.**). Nous avons aussi étudié l'influence de l'hypoxie sur les propriétés de sécrétion des EPC précoces et la capacité angiogénique et cardioprotectrice des facteurs libérés par les EPC précoces en conditions de normoxie et d'hypoxie. Le profil des cytokines des EPC précoces montre qu'ils sécrètent de nombreux facteurs pro-angiogéniques (VEGF, SDF-1, PIGF, Ang2, ET-1, IL-8, MCP-1, MMP10) et anti-angiogéniques (TIMP-1, CXCL4), ce qui suggère la contribution des EPC précoces à la maintenance de l'équilibre angiogénique qui pourrait empêcher l'angiogenèse pathologique. Nous avons également montré que, bien que l'hypoxie module le profil de sécrétion des EPC précoces, en augmentant la sécrétion globale des facteurs de croissance impliqués dans l'angiogenèse, y compris VEGF, ces changements n'influencent pas de manière significative l'effet angiogénique du milieu conditionné. Ainsi, on peut remarquer que les facteurs libérés par les EPC précoces, dans conditions normales aussi que dans les conditions de privation d'oxygène, sont capables d'induire la migration et la prolifération

des CE, l'organisation des EC en cordons et de protéger les myocytes cardiaques de l'apoptose induite par l'hypoxie. On a également étudié la contribution du VEGF aux propriétés angiogéniques des EPC précoces. Les résultats ont montré que la présence de VEGF dans le milieu conditionné des EPC précoces n'est pas essentielle pour la migration de des CE ou pour la formation des cordons des CE sur Matrigel.

Ensuite, on a étudié les propriétés paracrines des MSC, en suivant leur capacité à induire l'adhésion et la prolifération des CE et de protéger les myocytes cardiaques de l'apoptose induite par l'hypoxie (**Chapitre II.4.**). Également, le potentiel des MSC a été comparé à celui des EPC précoces et a été évalué dans des conditions hypoxiques. Les résultats ont montré que les facteurs sécrétés par les MSC stimulent le chimiotactisme et l'adhésion des CE, mais ils ne sont pas capables d'induire la prolifération des CE; en outre, ils ont des effets bénéfiques sur les cellules musculaires cardiaques ischémiques. L'activité sécrétoire des MSC est légèrement modifiée à la suite de l'exposition à l'hypoxie, mais apparemment ces changements n'affectent pas les effets paracrines. Les effets induits par les EPC précoces in vitro sont complémentaires à ceux induits par les MSC, en stimulant la prolifération, mais pas l'adhésion des CE. Ces deux effets peuvent être induits simultanément en combinant les milieux conditionnés, ce qui suggère que les facteurs libérés par chacun des deux types de cellules ne sont pas suffisants pour compléter l'angiogenèse. Ceci suggère que la combinaison de ces deux populations cellulaires ou des facteurs sécrétés par eux-mêmes, permettrait d'induire l'angiogenèse avec succès.

Le processus de neovasculogenèse dépend de l'activité des différentes cytokines tels que le VEGF, bFGF, les angiopoïétines et SDF-1 (-Wingerter Parsons et al., 2000 Visconti et al., 2002). Les mécanismes par lesquels ils orchestrent la néovascularisation sont encore contestés. On sait qu'au niveau d'un milieu ischémique, un gradient de SDF-1 est formé, ce qui provoque la mobilisation de cellules de moelle osseuse exprimant du CXCR4. En plus, l'interaction récepteur-ligand déclenche des cascades de signalisation impliquées dans la survie, la croissance et la prolifération cellulaires (Ganju et al. 1998 Petit et al. 2007, Roland et al., 2003). Dans ce contexte, nous avons investigué le profil d'expression du SDF-1 des EPC précoces et nous avons examiné si le rôle paracrine de ces cellules dans la néovasculogenèse est médié par SDF-1 (**Chapitre II.5.**).

De plus, étant donné que l'interaction SDF-1/CXCR4 est exploitée de plus en plus dans l'utilisation de la thérapie cellulaire après un IM (Zhang et al., 2007), nous avons étudié la fonction de CXCR4 dans le remodelage cardiaque après IM chez les souris génétiquement modifiées IM ($CXCR4^{+/-}$), afin d'identifier les éventuels effets néfastes des composés pharmacologiques (**Chapitre II.6.**). Les résultats ont montré que les EPC précoces sécrètent des quantités accrues de SDF-1 et sont capables de lier SDF-1 à leur surface, créant ainsi un gradient local qui attire des cellules souches / progénitrices $CXCR4^{+}$ au potentiel angio-/vasculogen en circulation. D'autre part, les études in vivo sur les souris transgéniques ont montré que CXCR4 a un effet à double tranchant sur le remodelage cardiaque après un infarctus du myocarde. Ainsi, d'une part, les souris $CXCR4^{+/-}$ ont présenté après IM des cicatrices plus petites et plus stables, associées avec une réponse monocytique plutôt régénératrice et une meilleure adaptation des myocytes cardiaques au stress hypoxique. D'autre part, la fonction des EPC précoces a été affectée, ce qui a résulté dans la réduction de la néovascularisation du myocarde et du rétablissement du débit coronaire, qui sont ensemble responsables de l'absence d'amélioration de la fonction ventriculaire. Ainsi, en extrapolant ces résultats, l'inhibition du CXCR4 dans le système humain doit être faite avec prudence.

En conclusion, les données contenues dans cette thèse démontrent que:

- Les EPC précoces et tardives peuvent être obtenues à partir du sang périphérique et du sang du cordon ombilical

- Le potentiel endothélial des cellules souches / progénitrices mésenchymateuses est limité, mais ce type de cellule peut être exploité pour stimuler la néovascularisation à l'aide de leurs propriétés paracrines

- Les facteurs libérés in vitro par les EPC précoces sont capables de stimuler de manière significative la formation de nouveaux vaisseaux par les EPC tardives ; ainsi, la transplantation des EPC précoces n'est pas nécessaire pour obtenir cet effet.

- Les EPC précoces maintiennent leurs propriétés paracrines en conditions hypoxiques et VEGF n'est pas essentiel pour leur effet angiogénique.

- Les facteurs paracrines sécrétés par CSM soutiennent certains des processus impliqués dans l'angiogenèse (soutiennent le chimiotactisme et l'adhésion des CE, mais pas la

prolifération) et ont des effets bénéfiques sur les myocytes cardiaques ischémiques ; ces propriétés sont maintenues lorsque les MSC sont soumis à l'hypoxie.

- Les effets induits in vitro des EPC précoces sont complémentaires à ceux induits par CSM ; ainsi ils stimulent la prolifération, mais pas l'adhésion des CE. Ces deux effets peuvent être induits simultanément en combinant les deux milieux conditionnés (obtenus à partir de la EPC et CSM). La combinaison de ces deux populations cellulaires ou des facteurs sécrétés par eux, pourrait être une stratégie efficace pour induire l'angiogenèse thérapeutique.

- Les EPC précoces sécrètent des quantités accrues de SDF-1 et sont capables de lier SDF-1 sur leur surface, créant ainsi un gradient local qui peut attirer du trafic de cellules souches / progénitrices $CXCR4^{+}$ au potentiel angio-/vasculogène vers un site ischémique.

- CXCR4 présente un effet à double tranchant sur le remodelage myocardique après un IM ; son expression faible cause la formation des cicatrices plus petites et plus stables, mais affecte la néovascularisation cardiaque et la récupération de la fonction ventriculaire.

Les points de repère fondés sur des résultats originaux obtenus pendant le stage doctoral permettent l'élaboration des stratégies qui conduiront à l'optimisation du traitement de vascularisation d'un territoire ischémique. Ces données précliniques seront renforcées dans le futur par des essais cliniques.

CUPRINSUL TEZEI DE DOCTORAT

INTRODUCERE

PARTEA I. STADIUL ACTUAL AL CUNOȘTINȚELOR

Capitolul I.1. Bolile cardiovasculare și necesitatea regenerării vasculare

Capitolul I.2. Structura vaselor de sânge

Capitolul I.3. Mecanismele fiziologice ale neovascularizării.

A. Vasculogeneza

B. Angiogeneza

i/ Angiogeneza prin înmugurire

ii/ Angiogeneza prin intussuscepțiune sau segmentare

C. Arteriogeneza

Capitolul I.4. Modele experimentale pentru studiul formării vaselor de sânge

Capitolul I.5. Factorii implicați în formarea vaselor de sânge

A. Factorul de creștere a endoteliului vascular (VEGF)

B. Angiopoietinele

C. Factorul de creștere a fibroblaștilor (FGF)

D. Factorul de creștere derivat din plachete (PDGF)

E. Chemokinele de tip CXC

F. Factorii anti-angiogeni

Capitolul I.6. Strategii de inducere a regenerării vasculare

A. Celulele stem în regenerarea vasculară

i/ Caracteristici generale ale celulelor stem

ii/ Celulele endoteliale progenitoare (EPC)

iii/ Celulele stem mezenchimale (MSC)

B. Studii experimentale și clinice asupra regenerării vasculare

PARTEA a II-a. CONTRIBUȚII ORIGINALE

Capitolul II.1. Celulele stem/progenitoare umane - sursă de celule endoteliale pentru refacerea perfuziei sanguine a unui teritoriu ischemic

A. Introducere și obiective

B. Obținerea EPC timpurii din sânge periferic

i/ Materiale și metode

ii/ Rezultate

C. Obținerea EPC târzii din sânge din cordonul ombilical

i/ Materiale și metode

ii/ Rezultate

D. Potențialul endotelial al celulelor mezenchimale izolate din gelatina Wharton

i/ Materiale și metode

ii/ Rezultate

E. Potențialul endotelial al celulelor stromale medulare

i/ Materiale și metode

ii/ Rezultate

F. Discuții și concluzii

Capitolul II.2. Potențarea efectelor EPC târzii de către factorii solubili secretați de EPC timpurii

A. Introducere și obiective

B. Materiale și metode

C. Rezultate și discuții

i/ Analiza imunofenotipică a EPC timpurii și târzii

ii/ Efectul cumulat al EPC târzii cu factorii solubili secretați de EPC timpurii asupra neovascularizării pe model de implant de matrigel *in vivo*

iii/ Efectul cumulat al EPC târzii cu factorii solubili secretați de EPC timpurii asupra neovascularizării pe model de ischemie femurală

D. Concluzii

Capitolul II.3. Secreția VEGF nu este esențială pentru efectul angiogen al EPC timpurii

A. Introducere și obiective

B. Materiale și metode

C. Rezultate și discuții

i/ Rezistența EPC timpurii la hipoxie

ii/ Proprietățile paracrine ale EPC timpurii în condiții normale și hipoxice

iii/ Factorii secretați de EPC timpurii în condiții normale și hipoxice

iv/ Contribuția VEGF la proprietățile paracrine angiogene ale EPC timpurii

D. Concluzii

Capitolul II.4. Efectul paracrin al factorilor secretați de celulele stem și progenitoare în stimularea agiogenezei

A. Introducere și obiective

B. Materiale și metode

C. Rezultate

i/ Rezistența MSC la hipoxie

ii/ Evaluarea comparativă a factorilor angiogeni secretați de MSC în condiții normoxice și hipoxice

iii/ Efectul protector al factorilor secretați de MSC normale și hipoxice asupra miocitelor cardiace

iv/ Proprietățile chemoatractante ale factorilor secretați de MSC normoxice și hipoxice

v/ Efectul factorilor secretați de MSC în condiții normale și hipoxice asupra aderării și proliferării celulelor endoteliale mature

vi/ Efectele opuse ale EPC și MSC asupra aderării și proliferării celulelor endoteliale mature

vii/ Analiza expresiei genice a celulelor endoteliale incubate simultan în prezența factorilor secretați de MSC și EPC timpurii

D. Discuții și concluzii

Capitolul II.5. Dubla proprietate a EPC timpurii de a secreta și capta SDF-1: un posibil mecanism pentru neovascularizare

A. Introducere și obiective

B. Materiale și metode

C. Rezultate și discuții

i/ Caracterizarea EPC timpurii

ii/ Analiza comparativă a expresiei SDF-1 în EPC timpurii și celulele endoteliale mature

iii/ Analiza comparativă a expresiei SDF-1în EPC timpurii și leucocitele mononucleate

iv/ Modularea expresiei SDF-1 de către mediatorii inflamației

D. Concluzii

Capitolul II.6. Rolul dual al axei SDF-1/CXCR4 în infarctul de miocard identificat în șoarecii transgenici deficienți în CXCR4

A. Introducere și obiective

B. Materiale și metode

C. Rezultate

i/ Caracterizarea infarctului de miocard la șoarecii transgenici deficienți în CXCR4

ii/ Analiza funcției cardiace post-infarct la șoarecii transgenici deficienți în CXCR4

iii/ Efectul negativ al CXCR4 de la nivelul celulelor medulare asupra funcției cardiace post-infarct

iv/ Rolul benefic al CXCR4 în mobilizarea și funcționalitatea EPC timpurii

v/ Evaluarea apoptozei în miocardul infarctizat la șoarecii transgenici deficienți în CXCR4

vi/ Particularitățile ultrastructurale ale miocardului la șoarecii transgenici deficienți în CXCR4

vii/ Proprietățile cardioprotectoare ale fosfatidil-serinei izolate din miocardul șoarecilor deficienți la CXCR4

D. Discuții și concluzii

REZUMATUL TEZEI DE DOCTORAT

În contextul actual în care bolile cardiovasculare reprezinta principala cauză de mortalitate, elucidarea mecanismelor care stau la baza procesului de formare de noi vase de sânge la adult (neovascularizare), preocupă intens comunitatea științifică. Deși numeroase studii experimentale și trialuri clinice care urmăresc utilizarea celulelor stem/progenitoare pentru inducerea angiogenezei și a miogenezei au indicat rezultate încurajatoare (Gersh et al., 2009; Heil and Schaper, 2004; Lipinski et al., 2007; Mitsos et al., 2012), mecanismele prin care populațiile individuale de celule stem/progenitoare contribuie la îmbunătățirea funcției cardiace post-infarct sunt încă incomplet înțelese (Gersh et al., 2009). O mai bună înțelegere a acestora ar putea crește eficiența terapiilor celulare. De asemenea, având în vedere mediul ischemic în care celulele stem ajung după transplantarea în miocardul infarctizat, la fel de importantă este și înțelegerea proprietăților paracrine ale celulelor stem în condiții hipoxice.

Aceasta ar permite imaginarea unor strategii terapeutice adaptate fiecărui pacient, care să depășească posibilele impedimente determinate de particularitățile patologice. Optimizarea strategiei s-ar putea face prin alegerea celei mai potrivite populații celulare sau a unor combinații de populații sau prin utilizarea doar a factorilor secretați de acestea, cât și prin alegerea căii de administrare și a momentului în raport cu producerea accidentului vascular acut. De asemenea, celulele ce vor fi injectate pot fi precondiționate prin stimularea cu diverse citokine sau prin blocarea ori supraexprimarea unor receptori (Herrmann et al., 2011; Richardson et al., 2013).

În acest context, lucrarea de față evidențiază populațiile de celule stem/progenitoare care prezintă potențial angio-/vasculogen și câteva dintre mecanismele prin care ele contribuie la neovascularizarea țesuturilor ischemice. Mai departe, țintind în primul rând îmbunătățirea funcției miocardului infarctizat, sunt urmărite nu doar efectele benefice ale acestor tipuri celulare asupra neovascularizării, dar și asupra protecției oferite miocitelor cardiace expuse la stresul hipoxic. De asemenea, studiile investighează care este contribuția diverșilor factori paracrini la potențialul terapeutic al celulelor stem/progenitoare și dacă hipoxia modifică expresia acestora sau proprietățile paracrine ale celulelor. În ultima parte este evaluată contribuția axei SDF-1/CXCR4 la rolul paracrin al celulelor progenitoare și funcția CXCR4 în remodelarea cardiacă după infarctul de miocard (IM).

Teza este structurată în două parți cuprinzând 143 figuri, dintre care 105 figuri în partea a doua, 7 tabele (în partea a doua), 290 de referințe bibliografice și se extinde pe parcursul a 233 pagini.

În prima parte, Stadiul actual al cunoștințelor, organizată în 6 capitole, sunt prezentate mai întâi posibilitățile terapeutice existente, fiind evidențiată necesitatea dezvoltării unor noi strategii terapeutice (**Capitolul I.1.**). Apoi, după o scurtă descriere a structurii vaselor de sânge (**Capitolul I.2.**), se face o incursiune în mecanismele fiziologice ale neovascularizării (**Capitolul I.3.**), fiind inițial definiți termenii de vasculo-, angio- și arteriogeneză. Etapele procesului de angiogeneză (reorganizarea membranei bazale, a matricei extracelulare, a citoscheletului în timpul migrarii celulelor endoteliale (CE), maturarea si stabilizarea vasului) sunt descrise în detaliu. În cel de-al patrulea capitol (**Capitolul I.4.**), sunt descrise câteva modele pe care poate fi studiată experimental formarea vaselor, iar în penultimul capitol (**Capitolul I.5.**) sunt prezentați factorii cheie care modulează neovascularizarea. Ultimul

capitol (**Capitolul I.6.**) este dedicat descrierii diverselor strategii prin care poate fi indusă neovascularizarea, fiind întâi trecute în revistă principalele tipuri de celule stem și proprietățile lor generale, fiind apoi detaliate caracteristicile a două tipuri de celule cu rol în neovascularizare: celulele endoteliale progenitoare (EPC) și celulele stem mezenchimale (MSC). În final este sintetizată situația actuală a studiilor experimentale și clinice, fiind descrise succesele și limitările acestora.

În a doua parte a lucrării, cea de Contribuții originale, studiile au fost organizate în șase capitole. Studiile inițiale s-au concentrat pe identificarea potențialului endotelial al unor populații de celule stem/progenitoare (**Capitolul II.1.**). Rezultatele arată că din sursele tisulare, adulte și fetale, utilizate (sânge periferic, sânge din cordonul ombilical, gelatina Wharton și măduva osoasă) pot fi obținute cele 2 tipuri de EPC descrise în literatură (timpurii și târzii) și celule stem/progenitoare de tip mezenchimal. Potențialul endotelial al acestora din urmă este redus, însă fenotipul secretor a sugerat urmărirea în continuare a proprietăților paracrine ale acestora, în scopul stimulării neovascularizării.

Numeroase studii susțin contribuția EPC timpurii și târzii la neovascularizare prin mecanisme separate, cele timpurii având rol paracrin, în timp ce EPC târzii, cu potențial proliferativ crescut, având capacitatea de a se încorpora în vasele în formare (Asahara et al., 1997; Hur et al., 2004; Sieveking et al., 2008). De asemenea, este recunoscut faptul că formarea de noi vase poate fi modulată prin utilizarea unor combinații de factori angiogenici, procesul putând fi amplificat atunci când acești factori sunt administrați / eliberați secvențial (Freeman and Cohen, 2009; Hao et al., 2007). Pe de altă parte, un studiu care a analizat efectul administrării concomitente a EPC timpurii cu cele târzii asupra neovascularizării, pe un model *in vivo* de ischemie femurală, a arătat că cele două tipuri celulare au efect sinergic (Yoon et al., 2005). Toate aceste date nasc întrebarea dacă efectul benefic obținut este dependent de factorii eliberați de EPC timpurii, ca urmare a unui răspuns dinamic al acestor celule la condițiile întâlnite *in vivo*. Pentru a răspunde la această întrebare, utilizând două modele *in vivo*, am urmărit dacă factorii secretați *in vitro* de EPC timpurii pot îmbunătăți neovascularizarea indusă de EPC târzii (**Capitolul II.2.**). Rezultatele obținute arată că, în prezența factorilor secretați de EPC timpurii *in vitro*, EPC târzii incluse într-un fragment de Matrigel, transplantat subcutanat la șoarece, se pot organiza în structuri vasculare ce fuzionează cu rețeaua vasculară a organismului gazdă. De asemenea, transplantarea EPC târzii, în prezența factorilor secretați de EPC timpurii, în

mușchiul ischemic, crește semnificativ perfuzia tisulară, efect care nu este obținut la un nivel similar și atunci când EPC târzii sau factorii secretați de EPC timpurii sunt administrați separat. Astfel, se poate concluziona că factorii eliberați *in vitro* de către EPC timpurii sunt capabili să stimuleze semnificativ formarea de noi vase de către EPC târzii, nefiind necesară administrarea EPC timpurii pentru obținerea acestui efect.

Identificarea factorilor din mediul condiționat, responsabili de efectul benefic, va permite formularea unui compus terapeutic care să poate fi produs la scară largă și să poată fi administrat, la un situs ischemic, împreună cu EPC târzii, în scopul îmbunătățirii perfuziei tisulare. Astfel, pornind de la rezultatele studiilor *in vivo*, am urmărit în continuare descrierea factorilor paracrini responsabili pentru efectul benefic al EPC timpurii (**Capitolul II.3.**). De asemenea, am urmărit și influența hipoxiei asupra proprietăților secretorii ale EPC timpurii și a capacității angiogene și cardioprotectoare a factorilor eliberați de EPC timpurii în condiții normoxice și hipoxice. Prin realizarea profilului citokinic al EPC timpurii se poate spune că acestea secretă numeroși factori pro-angiogeni (VEGF, SDF-1, PlGF, Ang2, ET-1, IL-8, MCP-1, MMP10), dar și factori anti-angiogeni (TIMP-1, CXCL4), EPC timpurii putând astfel contribui la menținerea unei balanțe angiogene, care ar putea preveni angiogeneza patologică. Am arătat de asemenea că, deși hipoxia modulează profilul secretor al EPC timpurii, putându-se remarca, în ansamblu, creșterea secreției factorilor implicați în angiogeneză, inclusiv a VEGF, aceste modificări nu influențează semnificativ efectul angiogen al mediului condiționat. Astfel, se remarcă faptul că factorii eliberați de EPC timpurii, atât în condiții normale, cât și în condițiile deprivării de oxigen, induc proliferarea și migrarea CE, organizarea CE în cordoane și protejează miocitele cardiace de apoptoza indusă de hipoxie. A fost investigată, de asemenea, contribuția VEGF la proprietățile paracrine angiogene ale EPC timpurii. Rezultatele au arătat că prezența VEGF în mediul condiționat de la EPC timpurii nu este esențială pentru migrarea CE sau pentru formarea cordoanelor de CE pe Matrigel.

În continuare, au fost investigate proprietățile paracrine ale celulelor stem mezenchimale (MSC), urmărind capacitatea lor de a induce aderarea și proliferarea CE și de a proteja miocitele cardiace de apoptoza indusă de hipoxie (**Capitolul II.4.**). De asemenea, potențialul acestora a fost comparat cu cel al EPC timpurii și a fost evaluat și în condiții hipoxice. Rezultatele au arătat că factorii secretați de MSC stimulează chemotaxia și aderarea CE, dar nu sunt capabili să inducă proliferarea CE; de asemenea, au efecte

benefice asupra miocitelor cardiace ischemice. Activitatea secretorie a MSC este ușor modificată ca urmare a expunerii la hipoxie, dar aceste modificări nu influențează în mod evident efectele lor paracrine. Efectele induse de EPC timpurii *in vitro* sunt complementare celor induse de MSC, stimulând proliferarea, dar nu și aderarea CE. Ambele efecte pot fi induse simultan prin combinarea celor două medii condiționate, ceea ce arată că factorii eliberați de fiecare dintre cele 2 tipuri celulare nu sunt suficienți pentru a desăvârși angiogeneza. Aceasta sugerează că prin combinarea acestor două populații celulare sau a factorilor secretați de ele, angiogeneza ar putea fi indusă cu succes.

Procesul de neovasculogeneză este dependent de activitatea a diverse citokine, precum VEGF, bFGF, angiopoietinele și SDF-1 (Parsons-Wingerter et al., 2000; Visconti et al., 2002). Mecanismele prin care acestea orchestrează neovascularizarea sunt încă disputate. Se cunoaște faptul că la un situs ischemic se formează un gradient de SDF-1 care determină mobilizarea din măduvă a celulelor care exprimă CXCR4 și faptul că interacțiunea ligandului cu receptorul declanșează cascade de semnalizare implicate în creșterea, proliferarea și supraviețuirea celulară (Ganju et al., 1998; Petit et al., 2007; Roland et al., 2003). În acest context am urmărit în continuare profilul expresiei SDF-1 al EPC timpurii și am investigat dacă rolul paracrin al acestor celule la neovasculogeneză este mediat prin SDF-1 (**Capitolul II.5.**). De asemenea, având în vedere că interacțiunea SDF-1/CXCR4 este exploatată din ce în ce mai mult în vederea terapiei cu celule stem după IM (Zhang et al., 2007), ne-am propus să studiem funcția CXCR4 în remodelarea cardiacă după IM la șoareci modificați genetic ($CXCR4^{+/-}$), în scopul identificării unor eventuale efecte nedorite pe care le pot avea compușii farmacologici (**Capitolul II.6.**). Rezultatele obținute au arătat că EPC timpurii secretă cantități crescute de SDF-1 și sunt capabile să lege SDF-1 de suprafața lor, creând astfel un gradient local care poate atrage din circulație celule stem/progenitoare $CXCR4^{+}$ cu potențial angio-/vasculogen. Pe de altă parte, studiile in vivo pe șoarecii transgenici demonstrează că CXCR4 prezintă un efect de sabie cu două tăișuri asupra remodelării miocardului după IM. Astfel, pe de-o parte, șoarecii $CXCR4^{+/-}$ au prezentat după IM cicatrici mai mici și mai stabile, aceasta asociindu-se cu un răspuns monocitar mai degrabă regenerator și o mai bună adaptare a miocitelor cardiace la stresul hipoxic. Pe de altă parte, acest lucru a fost balansat prin afectarea funcției EPC timpurii, reducerea neovascularizării miocardului și diminuarea refacerii fluxului coronarian, acestea fiind împreună responsabile pentru lipsa de îmbunătățire a funcției ventriculare. Astfel,

extrapolarea acestor rezultate pentru inhibarea CXCR4 în sistem uman trebuie să se facă cu precauție.

În concluzie, datele cuprinse in aceasta teza demonstrează că:

- EPC timpurii și târzii pot fi obținute din sânge periferic și din sânge din cordon ombilical

- Potențialul endotelial al celulor stem/progenitoare de tip mezenchimal este limitat, însă acest tip celular poate fi exploatat în scopul stimulării neovascularizării pe baza proprietăților paracrine

- Factorii eliberați *in vitro* de către EPC timpurii sunt capabili să stimuleze semnificativ formarea de noi vase de către EPC târzii, nefiind necesară transplantarea EPC timpurii pentru obținerea acestui efect.

- EPC timpurii își mențin proprietățile paracrine în hipoxie și VEGF nu este esențial pentru efectul angiogen al acestora.

- Factorii paracrini secretați de MSC suportă o parte dintre procesele implicate în angiogeneză (susțin chemotaxia și aderarea CE, dar nu și proliferarea) și au efecte benefice asupra miocitelor cardiace ischemice; aceste proprietăți se mențin și atunci când MSC sunt supuse hipoxiei.

- Efectele induse de EPC timpurii *in vitro* sunt complementare celor induse de MSC, stimulând proliferarea, dar nu și aderarea CE. Ambele efecte pot fi induse simultan prin combinarea celor două medii condiționate (obținute de la EPC și MSC). Astfel, combinarea acestor două populații celulare sau a factorilor secretați de ele, ar putea constitui o strategie terapeutică de succes pentru inducerea angiogenezei.

- EPC timpurii secretă cantități crescute de SDF-1 și sunt capabile să lege SDF-1 de suprafața lor, creând astfel un gradient local care poate atrage din circulație, la un situs ischemic, celule stem/progenitoare $CXCR4^+$ cu potențial angio-/vasculogen.

- CXCR4 prezintă un efect de sabie cu două tăișuri asupra remodelării miocardului după IM, expresia lui scăzută determinând formarea unei cicatrici mai mici și mai stabile, dar afectând neovascularizarea miocardului și refacerea funcției ventriculare.

Reperele stabilite pe baza rezultatelor originale obținute pe parcursul stagiului doctoral permit imaginarea unor strategii care să optimizeze terapiile de vascularizare a unui teritoriu ischemic. Aceste date de natură preclinică urmează a fi întărite în viitor de studii clinice.

PhD THESIS
-BOOK SUMMARY-

The involvement of protein tyrosine phosphatases (PTPs) in intracellular signalling

Coordinator:
Acad. Maya Simionescu

PhD student:
Andreea Miruna Nemecz

Bucharest
-2012-

CONTENTS

Part I- The current stage of knowledge

I. Phosphatases, regulators of homeostasis

1. Definition, mechanism of action and classification
2. Protein phosphatases (PPs)-classification

II. Protein Tyrosine Phosphatases (PTPs)

1. PTPs classification
2. PTPs structure
3. PTPs genetic
4. PTPs substrate recognition and catalytic mechanism
5. PTPs regulation
   a. Proteolytic cleavage
   b. Phosphorylation
   c. Dimerization
   d. Oxidation
   e. Other post translational modifications(sumoilation, acetylation)
   f. Inhibition of PTPs enzyme activity/protein expression

III. PTPs and intracellular signalling

1. Localization and cellular substrates
2. Vascular PTPs – the role in vascular physiology and pathology
   A. PTPs in endothelial cells
      a. PTPs involved in angiogenesis
         - VEGFR and PTPs
         - Tie2 and PTPs
      b. PTPs involved in adhesion and motility
         - Integrins and PTPs
         - PECAM and PTPs
      c. PTPs involved in intracellular adhesion
         - Cadherins and PTPs
   B. PTPs in smooth muscle cells
      PTPs involved in angiogenesis
         - PDGFR and PTPs
         - AT and PTPs
         - NO and PTPs
3. The PTPs involvement in diabetes mellitus
4. The role of PTPs in other diseases

Part II - Original contributions

A. INTRODUCTION AND OBJECTIVES

B. METHODOLOGICAL CONSIDERATIONS

C. EXPERIMENTAL STUDIES

I. „*in vitro*" experimental model – smooth muscle cells in culture; The effects of oxidative stress, of insulin stimulation and inhibitors on smooth muscle cells from vascular wall: affected molecules

1. The effect of *high glucose, oxidative stress* and i*nsulin* on *:*

- ERK ½ controlled mitogenic pathway
- metabolic pathway controlled by activated Akt
- signalling pathway controlled by dephosphorylating **PTP-1B**

Results and discussions

2. The effect of *high glucose* and *PDGF-BB growth factor* on **PTP-1B** and molecules from insulin signalling pathway

Results and discussions

3. The modulation of protein expression and activity of the molecules from insulin signalling pathway (ERK ½ , Akt and **PTP-1B**) with the help of *oxidants/antioxidants and inhibitors*

a. The effect of *oxidants and inhibitors*
Results and discussions
b. The influence of *antioxidants on the oxidation* induced by high glucose concentration, as well as PDGF-BB growth factor
Results and discussions

II. „*in vivo*" experimental model –Golden Syrian hamsters with streptozotocin diabetes; Phosphorylation/Dephosphorylation events in aorta
Results and discussions

III. Obese and obese-associated Type II diabetes patients; Molecules from insulin signalling pathway
Results and discussions

D. General discussions

Phosphatases are group of enzymes that dephoshorylate by removing a phosphate group from its substrate. They catalyse the hydrolysis of phosphoric acid monoesters in a phosphate ion and molecule with a free hydroxyl group. This action is directly opposite to that of phophorylases and kinases, which attach phosphate groups to their substrates by using energetic molecules like ATP.

Together with kinases, phosphatases regulate the phophorylation state of the cell. The balance between events controlled by these enzymes has an important role in intracellular signalling.

Since protein kinases (PKs) frequently phophorylates proteins substrates on tyrosine, serine and threonine residues, protein phophatases (PPs) exert the reversible effect engaging usually the same amino acids in proteins.

Protein tyrosine phosphatases (PTPs) are enzyme that removes phosphate groups from tyrosine residues in different proteins. Protein phophorylation on tyrosine residues (pTyr) is a common post-translational modification that can create novel recognition motifs for protein interactions and cell localization, affect protein stability and regulate enzyme activity. They can also be a key regulatory components in signal transduction pathways and they are very important in the control of cell growth, proliferation and differentiation.

PTPs are critical regulators of signal transduction under normal and pathophysiological conditions. These proteins exert a regulatory effect on signalling transduction at different levels by dephosphorylation of membrane receptors like protein tyrosine kinases (PTKs) and ionic channels. They can modulate signalling cascades by dephosphorylation of adaptor molecules, intracellular kinases and transcription factors. PTKs have been identified as targets for PTPs. Many PTPs dephosphorylates more than a PTK, and almost each PTK is dephosphorylated by more than a PTP.

Depending on substrate specificity, vascular PTPs contributes to vascular pathology. PTPs are critical regulators of tyrosine phosphorylation-dependent signalling events and may represent novel targets for therapeutic intervention in a variety of human diseases. PTPs are negative regulators of cell proliferation and mitogenic signalling cascades of Ang II, insulin, IGF-1, EGF and PDGF in several cell types, including vascular smooth muscle cells (VSMCs) (Marrero, 2004).

Because a critical regulatory step in insulin signal transduction is the dephosphorylation of signalling molecules by PTPs, it is plausible that enhanced activity of one or more PTPs could lead to insulin resistance (Choi et al., 2010).

The first part of my work „**The current state of knowledge**” presents PTPs throughout three chapters.

The first chapter presents classification and catalytic mechanism of phophatases. The balance between reactions exerted by phophatases and the one carried out by kinases seems to

be of the great importance in intracellular signalling. Phosphatases play a crucial role in homeostasis.

The second chapter describes PTPs classification and structure. Also, reveals some aspects regarding the substrate recognition and PTPs mechanism of action, as well as the main regulation processes for the action of PTPs.

In the last chapter it is shown the localisation of PTPs and their substrate molecules. This part of my work presents vascular wall-localised PTPs. Depending on cell type localisation, vascular PTPs regulate processes like angiogenesis, cell adhesion and motility. PTPs control signalling pathways involving growth factors and adhesion molecules. In this way PTPs have crucial role in vascular physiology and pathology. In the same chapter are presented PTPs that regulates insulin receptor signalling pathway. These enzymes play a substantial role in insulin signalling by reducing signalling and insulin receptor dephosphorylation. Along with diabetes mellitus there are also described some other pathologies in which PTPs play central roles. For PTPs activity, it is considerable the oxidation state of the enzymes, as well as the processes of oxidation/antioxidation developed at this level.

Our research, focused on finding new methods for PTPs activity manipulation, by using inhibitors and effects of oxidants/antioxidants on key molecules from insulin signalling pathway. Therefore in the second part of my work ''**Original contributions**", there have been two major objectives:

1. Analysing the hyperglycaemia-induced changes in PTP-1B protein level as well as in protein level of the kinases involved in insulin signalling pathway. ***(chapter I, II si III)***

1a.The hydrogen peroxide and insulin action consequences.

1b. The effects of growth factor PDGF-BB stimulation.

Experimental models:

- „*in vitro*", smooth muscle cells isolated from human aorta, cell line
- „*in vivo*", streptozotocin injected Golden Syrian hamsters
- human biological material, from obese and obese-associated Type II diabetic patients

2. Investigation of mechanisms by which oxidants/antioxidants and inhibitors act on PTP-1B and signalling kinases from insulin pathway ***(chapter I)***

2a. The role of high glucose (HG) and sodium orthovanadate.

2b. Modulation of molecules expression in hyperglycaemic conditions and PDGF-BB stimulation after catalase and superoxid dismutase action.

Model experimental:

- „*in vitro*", smooth muscle cells isolated from human aorta, cell line

GENERAL DISCUSSIONS:

Apprehending signalling pathways as well as molecules involved in vascular wall cell signalling, are critical for a better understanding of diabetes-associated endothelial dysfunctions.

In order to understand PTPs pathophysiology, structure and enzyme activity the studies conducted pursued two main objectives:

1. Protein level changes of the molecules from insulin signalling pathway induced by high glucose associated with growth factors and antioxidants stimulation ***(chapter I, II and III).***
2. The mechanisms by which antioxidants and inhibitors act on the molecules from insulin signalling pathway, reestablishing physiological function ***(chapter I).***

„Original contributions" results presented over three chapters:

1. High glucose, oxidative stress and insulin induce imbalance of insulin signalling molecules phosphorylation in SMCs. Hyperglycaemia determinates over expression of molecules (excepting activated Akt); oxidative stress has the same effect (less on PTP-1B); while insulin exerted antagonic effects on both molecules;

The originality of the study: ***I demonstrated that overexposure of SMCs to HG has a strong activating effect on Akt. ERK ½ was sensible to H_2O_2 , but not responsive to insulin action. Long-term exposure of SMCs to an even higher glucose concentration (i.e. 30 mM) leads to the occurrence of an additional band reactive with the PTP-1B antibody, of apparent molecular mass slightly higher than 51 kDa.***

2. Stimulation of SMCs with PDGF-BB determines an over expression of insulin signalling molecules. While PTP-1B protein expression is increased by PDGF-BB stimulation in a dose-dependent manner, pAkt and pERK ½ achieve a maximum value at 2 ng/ml.

The originality of the study consists of: ***stimulation with PDGF-BB of SMCs grown in high glucose, amplifies the PDGF-BB effect on insulin signalling molecules***.

3. Maintenance of SMCs in high glucose as well as in acute H_2O_2 stimulation, cause a diminished PTP activity duet to oxidation. $NaVO_4$, the PTPs nonspecific inhibitor, induces decrease of PTP-1B protein expression followed by molecular modification of pAkt and pERK ½.

The originality of the study : ***I established that part of endogenous oxidation (i.e. HG) and exogenous one (i.e. H_2O_2) responsible of PTPs reduced activation are reversible. In***

hyperglycaemia, some PTP-1B enzyme oxidations are also reversible, capable of influencing catalytic activity of this phosphatase and regulation of insulin signalling pathway. In high glucose conditions, $NaVO_4$ leads to PTP-1B down regulation in SMCs.

4. Overexposure of key molecules from insulin signalling pathway, following prolonged culture of SMCs in hyperglycaemic oxidant conditions, can be reversed by antioxidants. Catalase and superoxide dismutase are also able to re-establish protein levels of these molecules, increased due to oxidations as a consequence of PDGF-BB stimulation.

The originality of the study consists of: ***both antioxidants exercise strong effect on HG and PDGF-BB alone induced-oxidations, but especially on hyperglycaemia and PDGF-BB cumulative induced-oxidations.***

5. In streptozotocin injected Golden Syrian hamsters, diabetic hyperglycaemia imbalance the expression of phosphatases (i.e. PTP-1B) vs. kinases (i.e. PI_3K and activated Akt) in the insulin signalling pathway. This disequilibrium is associated with endothelial pronounced permeability and SMCs apoptosis, and can also underline the aortic wall dysfunction as consequence of many changes in these cells.

The originality of the study consists of: ***demonstration of circulating hyperglycaemia effects on the balance between kinases / PTP-1B that acts in aortic wall, in the case of Type I diabetes.***

6. Obesity, as well as obesity associated with Type II diabetes influence protein expression of molecules associated with insulin signalling. In arterioles from subcutaneous adipose tissue, obesity induces a down regulation of insulin signalling molecules. This process is slowed in the case of obesity associated with Type II diabetes

The originality of the study consists of: ***I concluded that in both obese patients and obese associated with Type II diabetes patients, the arterioles from subcutaneous adipose tissue showed changes in expression of insulin signalling molecules important in both diseases***.

The imbalance in hyperglycaemia-induced phosphorylation/dephosphorylation events are accompanied by multiple reversible and irreversible oxidations which can interfere in diabetes -associated vascular dysfunction of aortic wall. Using PTPs antioxidants as well as the inhibitors could reverse changes occurred in smooth muscle cells or endothelial cells and that may improve vascular function. Therefore considering PTPs therapeutic targets would bring new elements in cardiovascular pathophysiology.

CUPRINS

Partea I- Stadiul actual al cunostintelor

I. Fosfatazele, reglatorii homeostaziei

1. Definitia, mecanismul de actiune si clasificarea
2. Protein fosfatazele (PPazele)-clasificarea

II. Protein Tirozin Fosfatazele (PTPazele)

1. Clasificarea PTPazelor
2. Structura PTPazelor
3. Genetica PTPazelor
4. Recunosterea substratului de catre PTPaze si mecanismul lor catalitic
5. Reglarea PTPazelor
   a. Clivajul proteolitic
   b. Fosforilarea
   c. Dimerizarea
   d. Oxidarea
   e. Alte modificari postranslationale (sumoilarea, acetilarea)
   f. Inhibarea activitatii/expresiei PTPazelor

III. PTPazele si semnalizarea intracelulara

1. Localizari si substrate celulare
2. PTPaze vasculare-rol in fiziologia si patologia vasculara

A. PTPazele in celulele endoteliale

a. PTPaze implicate in angiogeneza
   - VEGFR si PTPazele
   - Tie2 si PTPazele

b. PTPaze implicate in adeziune si motilitate
   - Integrinele si PTPazelor
   - PECAM si PTPazele

c. PTPaze implicate in adeziune intercelulara
   - Caderinele si PTPazele

B. PTPaze in celule musculare netede

PTPaze implicate in angiogeneza
   - PDGFR si PTPazele
   - AT si PTPazele
   - NO si PTPazele

3. Implicarea PTPazelor in diabetul zaharat
4. Rolul PTPazelor in alte patologii

Partea II - Contributii originale

A. INTRODUCERE SI OBIECTIVE

B. METODOLOGIE EXPERIMENTALA

C. STUDII EXPERIMENTALE

I. <u>Model experimental „*in vitro*”- celule musculare netede in cultura</u>; Efectele stresului oxidativ, al stimularii cu insulina si al inhibitorilor, asupra celulelor musculare netede din peretele vascular: molecule afectate

1. Efectul *glucozei crescute , stresului oxidativ si insulinei* asupra *:*

- caii mitogenice controlate de ERK ½
- caii metabolice controlate de activarea Akt
- caii de semnalizare controlata de **PTP-1B** defosforilanta

Rezultate si discutii

2. Efectul *glucozei crescute si a factorului de crestere PDGF-BB* asupra **PTP-1B** si moleculelor din calea de semnalizare a insulinei

Rezultate si discutii

3. Modularea expresiei si activitatii moleculelor din calea de semnalizare a insulinei (ERK ½ , Akt si **PTP-1B**) cu *ajutorul oxidantilor/antioxidantilor si inhibitorilor*

a. *Efectul oxidantilor si inhibitorilor*

Rezultate si discutii
b. Influenta *antioxidantilor asupra oxidarilor* produse de concentratia ridicata de glucoza, precum si de factorul de crestere PDGF-BB
Rezultate si discutii

Fosfatazele sunt enzime care prin procesul de defosforilare, indeparteaza de la nivelul substratului o grupare fosfat, prin hidroliza monoesterilor acidului fosforic in ioni fosfat si molecule cu grupari hidroxil libere. Acest proces este opus procesului de fosforilare, catalizat de enzime numite kinaze, care ataseaza grupari fosfat la nivelul substratului utilizand moleculele energetice, precum ATP.

Ambele tipuri de enzime sunt responsabile de controlul starii de fosforilare a celulei, echilibrul dintre procesele reglate de acestea ocupand astfel un rol important in cadrul semnalizarii intracelulare.

Protein fosfatazele (PPazele) sunt fosfataze care defosforileaza exclusiv substraturi proteice, tinta lor reprezentand anumiti aminoacizi din structura unei proteinei. Cei mai intalniti aminoacizii defosforilati sunt: serina (Ser), treonina (Thr) si mai rar tirozina (Tyr), intrucat proteinele sunt predominant fosforilate de protein kinaze (PKaze) la gruparile acestor aminoacizi.

Protein tirozin fosfatazele (PTPazele) sunt enzime care inlatura grupuri de fosfat din cadrul resturilor de Tyr fosforilata ale diferitelor proteine. Fosforilarea proteinelor la aminoacidul Tyr (pTyr), este o modificare post-translationala obisnuita care formeaza noi motive de recunoastere pentru interactia proteinelor si localizarile celulare, aceasta modificare putand afecta stabilitatea proteinelor si regla activitatea enzimatica. Fosforilarea proteinelor la resturi de tirozina reprezinta un mecanism cheie pentru transmiterea semnalului si pentru reglarea unui spectru larg de procese fiziologice precum controlul greutatii, proliferarii si diferentierii celulare.

PTPazele sunt reglatori ai transmiterii semnalului, atat in conditii fiziologice, dar si patologice. Aceste proteine exercita un efect reglator asupra transmiterii de semnal la diferite nivele prin defosforilarea receptorilor de membrana cum ar fi PTKazele si canalele ionice. Ele pot modula cascada de semnalizarea prin defosforilarea moleculelor adaptor, kinazelor intracelulare si a factorilor de transcriere. PTKazele au fost identificate ca fiind tinte pentru PTPaze. O serie de PTPaze defosforileaza mai multe PTKaze, si aproape fiecare PTKaza este defosforilata de mai mult decat o PTPaza.

PTPazele exprimate in celulele vasculare in functie de specificitatea de substrat, contribuie la patologia vasculara. PTPazele sunt reglatori importanti ai etapelor semnalizarii dependente de fosforilarea tirozinica, devenind astfel noi tinte terapeutice intr-o serie de afectiuni patologice. PTPazele sunt reglatori negativi ai proliferarii celulare si ai numeroaselor cascade mitogenice: Ang II, INS, IGF-1, EGF, PDGF in numeroase tipuri celulare, printre care si celulele musculare netede vasculare (Marrero, 2004).

Intrucat un pas reglator important in transmiterea semnalului de-a lungul caii activate de insulina il reprezinta defosforilarea moleculelor de semnalizare de catre PTPaze, este destul de probabil ca amplificarea activitatii uneia sau a mai multor PTPaze sa conduca la rezistenta la insulina (Choi si colab., 2010).

.

In prima parte a tezei „ **Stadiul actual al cunostintelor”,** sunt prezentate pe parcursul a trei capitole diferite aspecte privind PTPazele

Capitolul I descrie fosfatazele, clasificarea si mecanismul lor de actiune. De asemenea este subliniata importanta echilibrului dintre procesele catalizate de fosfataze si cele catalizate de kinaze in cadrul semnalizarii intracelulare, fosfatazele avand un rol deosebit de important in homeostazie.

Capitolul al-II-lea prezinta PTPazele, clasificarea, structura si genetica acestora. Tot in acest capitol sunt prezentate aspecte privind recunosterea substratului si mecanismul de actiune al PTPazelor, dar si principalele procese prin care ele sunt reglate.

Capitolul al-III-lea descrie localizarea PTPazelor si moleculele substrat ale acestora, insistandu-se pe PTPazele localizate la nivelul peretelui vascular. In functie de tipul celular la nivelul caruia sunt localizate, PTPazele vasculare participa la procese precum angiogeneza, adeziunea si motilitatea celulara. Ele regleaza caile de semnalizare ale factorilor de crestere si moleculelor de adeziune, avand in acest fel un rol important in fiziologia si patologia vasculara. Tot in cadrul acestui capitol sunt prezentate PTPazele care intervin de-a lungul caii de semnalizare a receptorului la insulina, controlandu-i astfel activitatea. PTPazele atenueaza semnalizarea la insulina prin defosforilarea receptorului sau, avand astfel un rol important in calea de semnalizare a insulinei. Alaturi de diabetul zaharat, sunt prezentate aici si alte patologii in care PTPazele au rol de reglatori centrali. Se subliniaza importanta starii de oxidare a PTPazelor in activitatea lor intracelulara, precum si a proceselor oxidative/antioxidative desfasurate la acest nivel.

Cercetarile noastre s-au concentrat asupra identificarii unor noi metode de manipulare a activitatii PTPazelor, prin utilizare inhibitorilor si efectele oxidantilor/antioxidantilor asupra moleculelor cheie din calea de semnalizarea a insulinei. In acest sens, in cadrul partii a II-a a tezei ”**Contributii originale”,** am incercat sa urmaresc doua mari obiective:

1. Determinarea modificarilor inregistrate la nivelul PTP-1B si a kinazelor implicate in calea de semnalizare a insulinei in hiperglicemie ***(capitolul I, II si III)***

1a. Consecintele prezentei apei oxigenate si a insulinei.

1b. Efectele stimulante ale factorul de crestere PDGF-BB

Modele experimentale:

- *„in vitro”,* celule musculare netede izolate din aorta umana, linie celulara
- *„in vivo”,* hamsteri sirieni aurii injectati cu streptozotocina
- material biologic uman, provenit de la pacienti obezi si obezi cu diabet II

2. Investigarea mecanismelor prin care oxidantii/antioxidantii si inhibitorii actioneaza asupra PTP-1B si a kinazelor din calea de semnalizare a insulinei ***(capitolul I)***

2a. Rolul actiunii glucozei crescute si a ortovanadatului de Na.

2b. Modularea expresiei moleculelor in conditii de hiperglicemie si stimulare cu PDGF-BB sub actiunea catalazei si a superoxid dismutazei.

Model experimental:

- „in vitro", celule musculare netede izolate din aorta umana, linie celulara

CONCLUZII GENERALE:

Cunoasterea cailor si moleculelor de semnalizare ale celulelor peretelui vascular, sunt esentiale pentru intelegerea disfunctilor endoteliale asociate diabetului.

In contextul intelegerii patofiziologiei PTPazelor, structurii si activitatilor enzimatice, studiile realizate in aceasta teza de doctorat au urmarit 2 obiective majore:

1. modificarile inregistrate la nivelul moleculelor caii de semnalizare a insulinei in conditii de glucoza crescuta urmarind asocierea hiperglicemiei cu factorii de crestere si oxidanti ***(capitolul I,II si III).***

2. mecanismele prin care antioxidantii si inhibitorii actioneaza asupra moleculelor din calea de semnalizare a insulinei, restabilind functia fiziologica ***(capitolul I).***

Rezultatele originale obtinute si prezentate pe parcursul celor 3 capitole in partea de „Contributii originale", au dovedit ca:

1. Glucoza crescuta, stresul oxidativ si insulina, sunt factori care duc la un dezechilibru al moleculelor caii de semnalizare a insulinei la nivelul CMNV. Hiperglicemia determina supraexprimarea acestor molecule cu exceptia Akt activat; stresul oxidativ are acelasi efect, mai putin asupra PTP-1B; in timp ce insulina are efecte antagonice asupra celor doua molecule.

Originalitatea studiului: ***am aratat ca expunerea CMNV pe timp indelungat la HG, are un puternic efect activator asupra Akt. De asemenea, tot la nivelul CMNV, ERK ½ manifesta sensibilitate la H_2O_2, ramanand insa insensibil la actiunea insulinei. Expunerea prelungita a celulelor la o concentratie si mai mare de glucoza (ex. 30 mM) duce la aparitia unei a doua benzi situata desupra benzii de masa moleculara de 51 kDa.***

2. Stimularea CMNV cu PDGF-BB determina o supraexprimare a moleculelor din calea de semnalizare a insulinei. In timp ce expresia proteica a PTP-1B creste proportional cu concentratia de PDGF-BB utilizata, pAkt si pERK ½ ating un maxim la 2 ng/ml.

Originalitatea consta in: ***stimularea cu PDGF-BB a CMNV crescute in conditii de hiperglicemie, amplifica efectul avut de acesta asupra moleculelor din calea de semnalizare a insulinei***.

3. Cresterea CMNV in glucoza crescuta, precum si stimularea acestora cu H_2O_2 duce la o scadere a activitatii PTPazelor datorata oxidarilor produse. Inhibitorul nespecific al PTP-azelor, $NaVO_4$, determina scaderea expresiei proteice a PTP-1B, inhibitia acestei fosfataze determinand ulterior modificari ale expresiei pAkt, dar si pERK ½.

Originalitatea studiului : ***am demonstrat ca o parte din oxidarile endogene (HG) si exogene (H_2O_2) responsabile de scaderea activitatii PTPazelor sunt reversibile. De asemenea, in hiperglicemie, la nivelul enzimei PTP-1B se produc o serie de oxidari, o parte din ele reversibile, oxidari ce ar putea influenta activitatea catalitica a acestei fosfataze si implicit reglarea caii de semnalizare in care aceasta joaca un rol important. In conditii hiperglicemice, inhibitorul $NaVO_4$, scade expresia PTP-1B in CMNV.***

4. Supraexprimarea moleculelor cheie din calea de semnalizarea a insulinei, consecinta a expunerii CMNV conditiilor hiperglicemice oxidante, poate fi reversata cu ajutorul antioxidantilor. De asemenea, atat catalaza cat si SOD restabilesc nivelele proteice ale acestor moleculelor, amplificate in urma oxidarilor produse prin stimularea CMNV cu PDGF-BB.

Originalitatea consta in: ***cei doi antioxidanti au efect asupra oxidarilor produse de HG si PDGF-BB individual, dar mai ales asupra puternicului efect oxidant produs de stimularea cu PDGF-BB a CMNV crescute in conditii hiperglicemice/oxidarilor asociate hiperglicemiei survenite la nivelul moleculelor stimulate cu PDGF-BB***

5. In cazul hamsterilor injectati cu streptozotocina, hiperglicemia diabetica determina un dezechilibru in exprimarea proteica a fosfatazelor (PTP-1B) vs. kinazelor (PI_3K si Akt) implicate in calea de semnalizarea a insulinei. Dezechilibrul este asociat cu hiperpermeabilitatea endoteliala si cu apoptoza celulelor musculare netede, si poate sublinia disfunctia peretelui aortic indusa de modificarile acestor celule.

Originalitatea consta in: ***demonstrarea efectelor concentratiei crescute de glucoza circulanta asupra balantei kinazelor/PTP-1B care actioneza la nivelul peretelui aortic, in cazul diabetul de tip I.***

6. Atat obezitatea, dar mai ales obezitatea asociata diabet II, influenteaza expresia moleculelor din calea de semnalizare a insulinei. In arteriolele tesutului adipos subcutan, obezitatea induce o scadere a expresiei proteice a moleculelor din calea de semnalizarea a insulinei, proces incetinit in cazul asocierii obezitatii cu diabetul tip II.

Originalitatea consta in: ***am aratat in paralel ca arteriole subcutane umane de la pacientii obezi si obezi cu diabet tip II prezinta modificari la nivelul moleculelor caii de semnalizare a insulinei cu rol important in evolutia celor doua patologii***.

Dezechilibrul glicemic induce procesele de fosforilare/defosforilare, insotite de multiplelor oxidari reversibile si ireversibile. Toate acestea pot interveni in disfunctia vasculara a peretelui aortic asociata diabetului. Utilizarea antioxidantilor si inhibitorilor de PTPaze poate corecta dereglarile survenite la nivelul celulelor musculare si endoteliale si poate imbunatati functia vasculara. In acest sens utilizarea PTPazelor drept tinte terapeutice poate aduce elemente noi in patofiziologia cardiovasculara.

Contract PN-III-P4-ID-PCE-2020-2465

nr. PCE 68/2021

Etapa 1 (2021): Conceperea, prepararea și caracterizarea nanocărăușilor pentru livrarea țintită a resolvinelor

Rezumatul etapei 1/2021:

Au fost obținute 3 tipuri de nanocărăuși încărcați cu resolvine, și anume nanoemulsii lipidice (P-NC/Res), nanoemulsii lipidice conjugate cu peptide de recunoaștere specifică a unor epitopi vasculari (T-NC/Res) și nanocărăuși biomimetici obținuți folosind membrane celulare izolate din monocite/ macrofage (Bio-NC/Res). Caracterizarea fizico-chimică a nanocărăușilor încărcați cu resolvine a constat în determinarea dimensiunii, încărcării electrice de suprafață, a eficienței de încorporare a resolvinelor în nanocărăuși și a stabilității acestora în timp și în medii biologice.

Au fost indepliniți toți indicatorii de realizare propuși, și anume: 1 raport cu privire la obținerea și caracterizarea fizico-chimică, la scară de laborator, a diverselor tipuri de nanocărăuși încărcați cu resolvine depus la UEFISCDI, diseminarea rezultatelor prin realizarea paginii web a proiectului (http://www.icbp.ro/static/en/en-networking_grants-grants-national_grants/nanores.html) și participarea cu 6 lucrări la Conferinte naționale și internaționale (4 prezentări orale și 2 postere). În plus, au fost publicate 2 articole în reviste cotate ISI.

Etapa 2 (2022): Validarea preclinică a nanocărăușilor concepuți pentru livrarea țintită a resolvinelor - studii in vitro

Rezumatul etapei 2/2022:

În etapa 2/2022 a proiectului NANORES, au fost efectuate studii pentru evaluarea citocompatibilității nanocărăușilor încărcați cu resolvine, preluarea acestora de către celulele peretelui vascular (celule endoteliale și celule musculare netede) și celule ale sistemului imun (macrofage) și au fost determinate proprietățile lor anti-inflamatorii.

Au fost indepliniți toți indicatorii de realizare asumați pentru etapa nr. 2, și anume:

● **1 raport** cu privire la citocompatibilitatea diferitelor tipuri de nanocărăuși încărcați cu resolvine, preluarea acestora de către celulele peretelui vascular și investigarea proprietăților lor anti-inflamatorii trimis la UEFISCDI;

● **diseminarea rezultatelor** prin participarea cu **7 lucrări la Conferinte naționale și internaționale** (2 prezentări orale și 5 postere) și **trimiterea spre publicare** a unui articol în revista ISI, Journal of Controlled Release, factor de impact 11.47.

● **Pagina web** a proiectului este disponibilă la adresa http://www.icbp.ro/static/en/en-networking_grants-grants-national_grants/nanores.html.

Scientific Report (02/05/2018 — 20/12/2018)

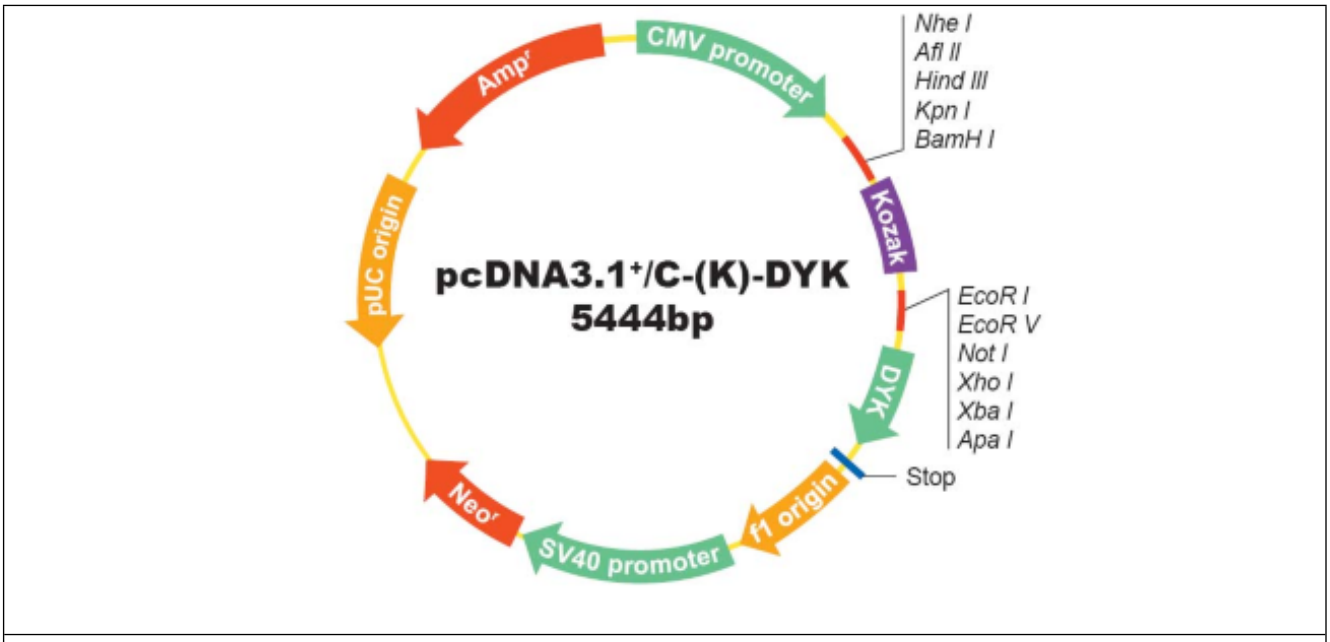
Project PN-III-P1-1.1-PD-2016-1942

"Evaluation of the therapeutic potential of non-viral apolipoprotein E gene transfer to limit progression of atherosclerosis"

Generation of non-viral transfection agents for expression of apoE3 or its fragments

1. Cloning of apoE3 sequence or its N-/C-terminal deletion fragments in a non-viral vector

The human apoE3 sequence and the N-/C-terminal regions were cloned into the non-viral vector pcDNA3.1+C-K-DYK. Driven by a CMV promoter, this expression vector for mammalian cells is equipped with a C-terminal DYK tag for easy protein detection.



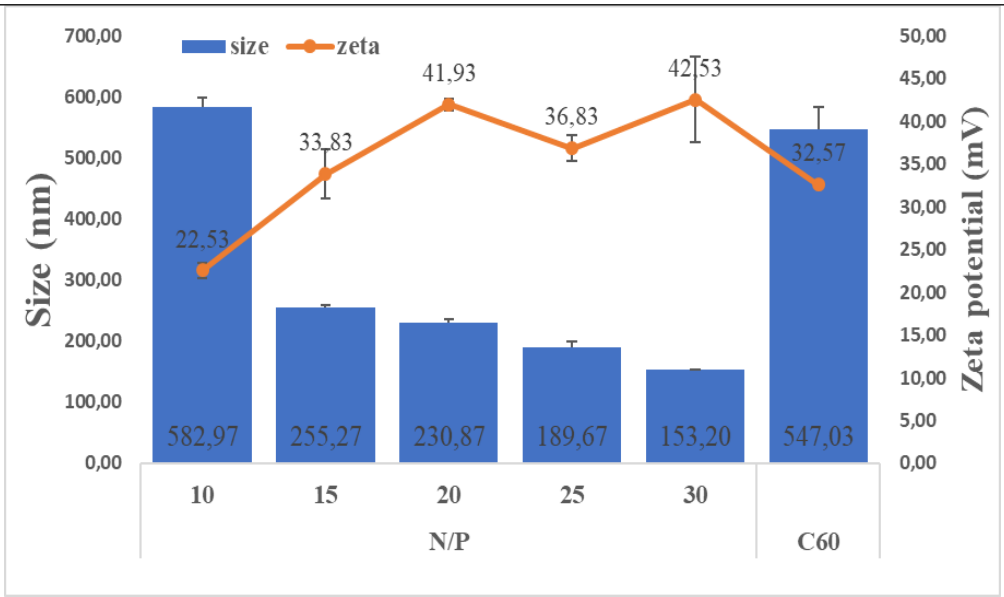
Schematic representation of the non-viral vector pcDNA3.1+C-K-DYK (5444 pb).

The entire apoE3 sequence was cloned into pcDNA3.1+C-K-DYK in EcoRI and XbaI sites. In addition, in the non-viral vector pcDNA3.1+C-K-DYK the following apoE fragments were cloned:

1. apoESSH1H2: containing the signal sequence and the first two helixes
2. apoESSH1H2RBR: containing the signal sequence, two helixes, the receptor binding region
3. apoESSH1H2RBRLBR: containing the signal sequence, two helixes, the receptor binding region and the lipid binding region
4. apoEwoRBR: containing the entire apoE sequence except for the receptor binding region
5. apoEwoLBR: containing the entire apoE sequence except for the lipid binding region

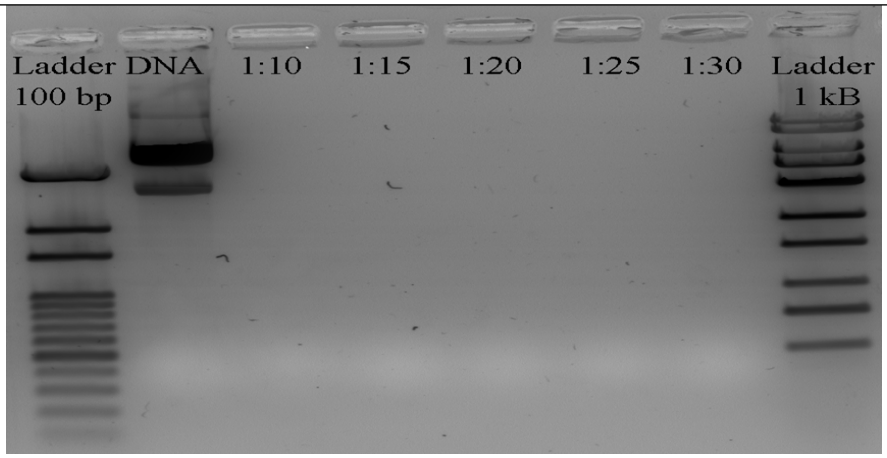
2. Coupling of the obtained plasmids to fullerene (C60) using polyethyleneimine (PEI)

To determine the optimal ratio of C60-PEI – DNA (non-viral vector) in order to obtain C60-PEI-DNA polyplexes, the C60-PEI conjugates were incubated with DNA at various N/P ratios (1:10, 1: 15, 1:20, 1:25 and 1:30), where N represents the nitrogen content of C60-PEI, and P represents the phosphorus content of the DNA. The size and zeta potential of the polyplexes were determined using a Nanosizer (Malvern). As indicated in the following figure, the C60-PEI conjugate exhibits a size of ~547 nm and a zeta potential of ~32.5 mV. In this case, the value of the hydrodynamic diameter is high and it can be attributed to expanding of the PEI chains, forming a physical network. C60-PEI-DNA polyplexes have sizes in the range 153-582 nm and zeta potential in the range of 22.5-42 mV. In the case of C60-PEI-DNA polyplexes with increasing N/P ratio, there is a decrease in size as well as an increase in zeta potential.



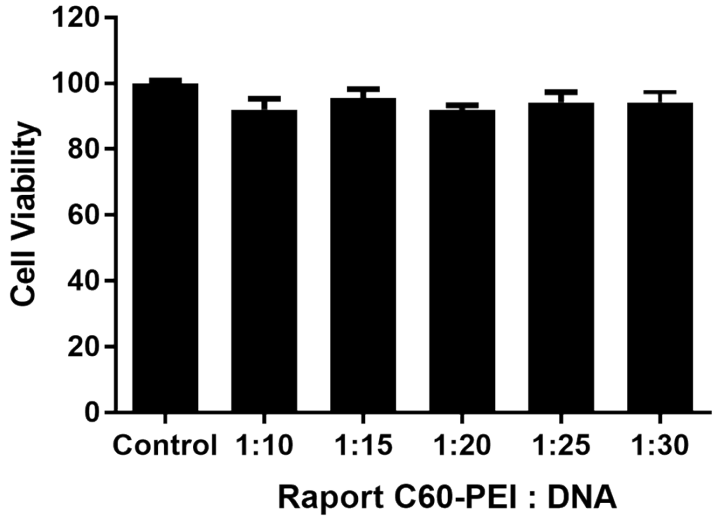
Size and zeta potential of C60-PEI-DNA polyplexes at the following N/P ratios: 1:10, 1:15, 1:20, 1:25, 1:30.

The ability of the C60-PEI conjugate to bind DNA was tested agarose gel retardation assays. The C60-PEI conjugates were incubated with DNA at various N/P ratios (1:10, 1:15, 1:20, 1:25, 1:30). The DNA concentration was maintained constant (1 μg/well) and the C60-PEI concentration increased according to the N/P ratio used (1:10, 1:15, 1:20, 1:25, 1:30). As shown in the figure below, the C60-PEI polyplexes have an excellent DNA binding capability since for all N/P ratios tested (including low N/P ratios, such as 1: 1 and 1:10) the DNA was complexed by C60-PEI. These results demonstrate that C60-PEI can be used in the generation of C60-PEI-DNA polyplexes at low N/P ratios for cell transfection purposes.



Testing the C60-PEI capacity to bind DNA by agarose gel retardation assays.

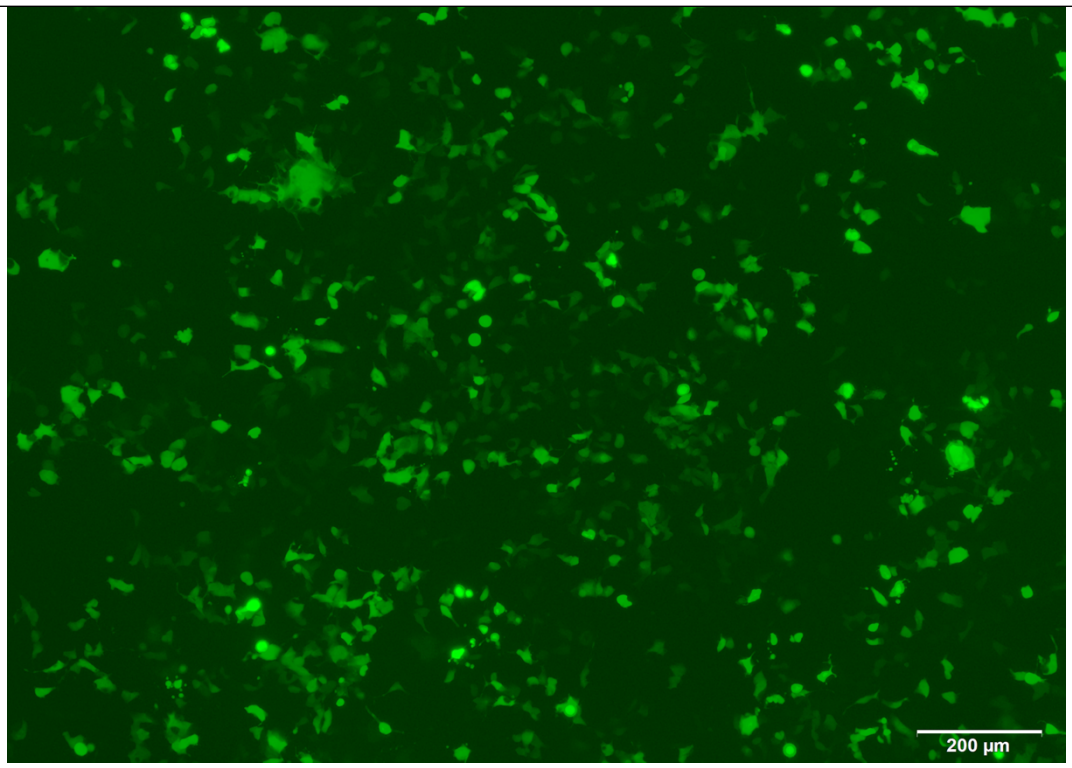
The viability of AD293 cells in the presence of C60-PEI-DNA polyplexes with various N/P ratios was determined by XTT technique. Cells were seeded in 96-well plates at a density of 10,000 cells/well in quadruplicate. One the day after seeding, C60-PEI-DNA polyplexes with various N/P ratios (1:10, 1:15, 1:20, 1:25 and 1:30) were added to the adherent cells. After 48 hours of incubation, cell viability in the presence of C60-PEI-DNA polyplexes was determined by XTT technique. As shown in the following figure, the C60-PEI-DNA polyplexes (irrespective of the N/P ratio used) have not significantly influenced cell viability, suggesting that C60-PEI-DNA polyplexes can be used in cell transfection processes.



The effect of C60PEI DNA polyplexes on cell viability.

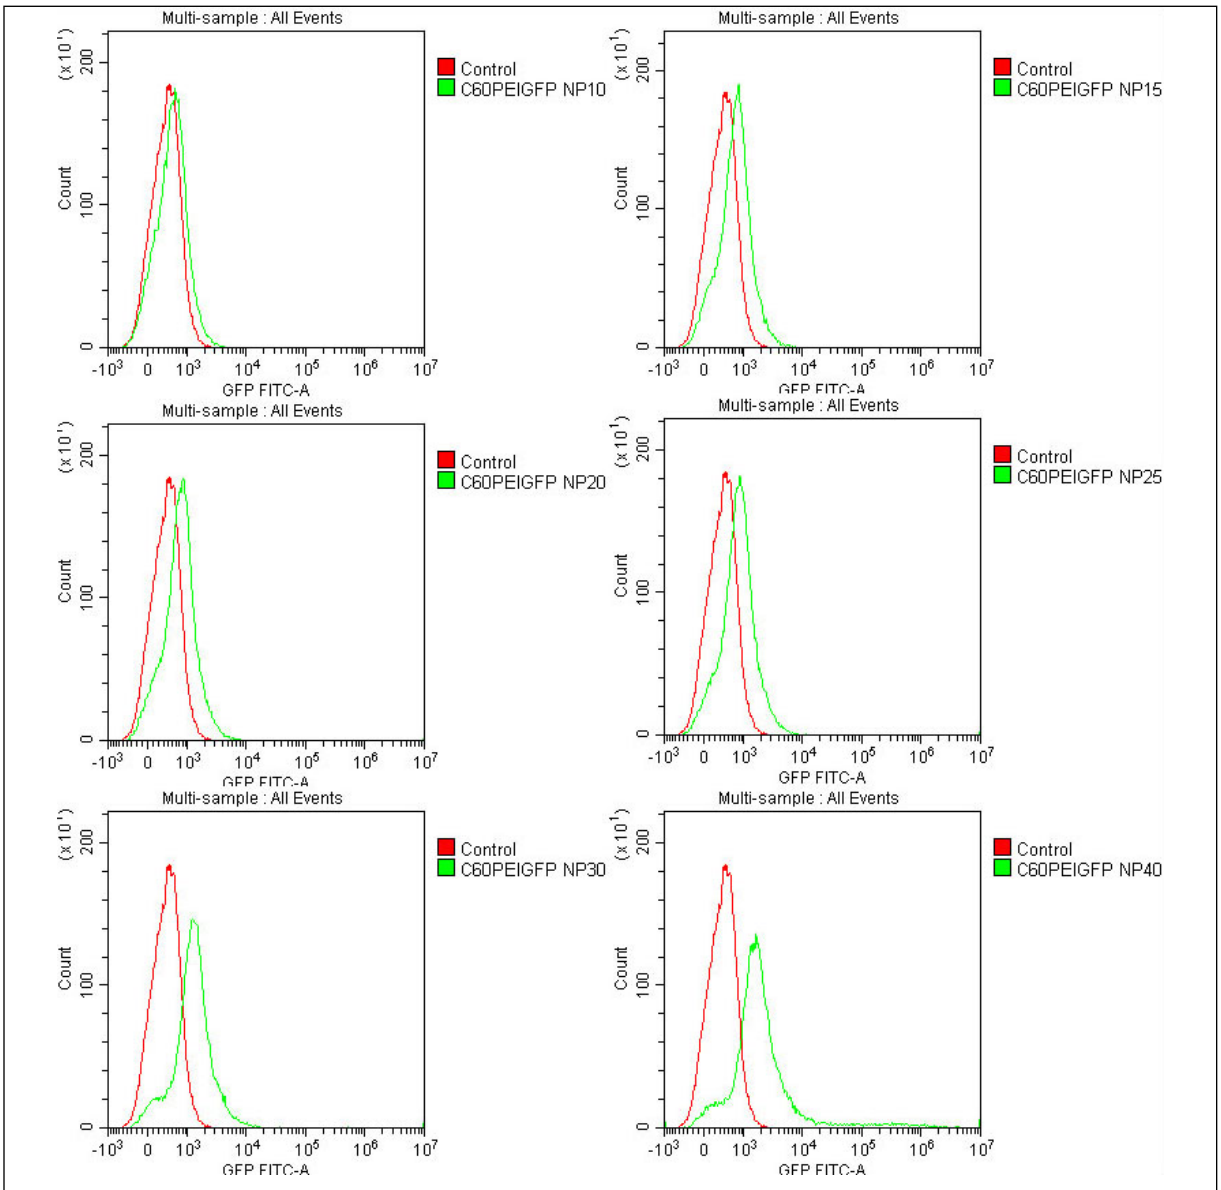
3. Testing the functionality of C60-apoE/GFP polyplexes as non-viral transfection agents

To test whether C60-PEI-DNA polyplexes can be used as transfection agents, the C60-PEI conjugates have been complexed with a specific DNA able to induce green fluorescence protein (GFP) expression that can be monitored by fluorescence microscopy. As illustrated in the following figure, AD293 cells were successfully transfected with C60-PEI-pGFP polyplexes.



AD293 cells transfected with C60-PEI-pGFP (this image was taken using a fluorescence microscope).

GFP expression in AD293 cells transfected with C60-PEI-pGFP polyplexes was also evaluated by flow cytometry. For this, AD293 cells were transfected with C60-PEI-pGFP polyplexes at various N/P ratios (1:15, 1:20, 1:25, 1:30, 1:40) and GFP expression was analyzed using a flow cytometer (Cytoflex). As shown in the figure below, GFP expression in cells transfected with C60-PEI-pGFP polyplexes increases as the N/P ratio increases.



Flow cytometry analysis of cells transfected with C60-PEI-pGFP polyplexes using increasing N/P ratios: 1:10, 1:15, 1:20, 1:25, 1:30, 1:40.

In conclusion, the results obtained this year in this project are summarized below:

1. The total sequence of apoE3 and five fragments of apoE were cloned into the non-viral vector pcDNA3.1+C-K-DYK
2. The obtained plasmids were coupled to fullerene (C60)-polyethyleneimine (PEI)
3. Functionality of C60-PEI-GFP polyplexes as non-viral transfected agents has been demonstrated *in vitro:* AD293 cells were successfully transfected with C60-PEI-pGFP (as shown by fluorescence microscopy, immunoblotting and flow cytometry experiments)

Dissemination of results:

1. Bisphenol A down-regulates hepatic apolipoprotein A1 expression, VG. Trusca, M. Dumitrescu, IM. Fenyo, IF. Tudorache, AV. Gafencu, poster presented at „ The 10th National Congress with International Participation and the 36th Annual Scientific Session of the Romanian Society of Cell Biology" Craiova, Romania, 6-9 June 2018
2. Bisphenol A down-regulates apolipoprotein A1 expression and exerts pro-atherogenic effects, VG. Trusca, M. Dumitrescu, IM. Fenyo, IF. Tudorache, AV. Gafencu, poster presented at "The 12th Central and Eastern European Proteomic Conference", Bucharest, Romania, 24 - 26 October, 2018

The results obtained in the project are part of a manuscript in preparation.

Tissue engineering of blood vessels using three-dimensional bioprinting of endothelial and smooth muscle progenitor cells

PN-III P1-1.1-PD-2016-1660

Phase II report – 2019

Abstract

Although autologous vascular grafts are the gold standard for clinical use, they are not suitable for a large number of patients due to vascular disease, amputations or previous vascular tissue harvesting. Despite the clear clinical needs of vascular substitutes, currently available synthetic grafts have proven to be successful only in large-calibre implant implants; small diameter vascular substitutes (<6 mm) have generally unsatisfactory results, with major negative side effects, such as acute thrombosis, hyperplasia and aneurysm. Therefore, biomimetic reconstruction of blood vessels through tissue engineering remains a difficult task that requires new construction techniques. The project aims to realize bioprinted vascular structures and to investigate the biocompatibility of endothelial and muscle progenitor cells in the presence of collagen and hyaluronic acid hydrogels. The obtained results showed that the cells are viable in the presence of the 3 hydrogels for 21 days. Endothelial and muscle progenitor cells are not subjected to oxidative stress and proliferate better in the presence of hydrogels than when grown in culture plates (2D system). The most intense proliferation was recorded in the hydrogel with 50% hyaluronic acid (H50), both at 7 days and at 21 days, respectively. In vascular constructs the level of VEGF is higher than in 2D system at 7 days. After 21 days of cultivation, the concentration of VEGF in vascular constructs H50 was 0.29 ng/ml, in H25 0.19 ng/ml and in H0 0.21 ng/ml comparable to EPCs cultured in 2D system (0.2 ng/ml). Also, the detection of VEGF in the EPC cultures obtained from AFSC shows that the differentiation towards the endothelial line occurred. The highest amount of nitric oxide was identified in the H50 hydrogel reaching values of 10.7 μM and 5.65 μM at 7 days and 21 days respectively. The results show that EPC and SPC express CD44 at 100% and CD49e at 99% for EPC and 94% for SPC. EPC shows increased expression for the CD54 (25%), CD56 (38%), CD105 (95.5%) markers. Also, markers CD73, CD90, and CD146 are expressed by both EPC and SPC in percentages between 70-100%. The hydrogels have a porous structure, forming large pores with a diameter between 40-150 μM. In the presence of hydrogels, the cells have a fusiform morphology and emit filopods that allow the interaction between cells and with collagen fibres.

Introduction

Cardiovascular diseases are the leading causes of mortality worldwide and require over one million bypass / blood vessel replacements annually in the United States alone [1]. Although autologous vascular grafts are the gold standard for clinical use, they are not suitable for a large number of patients due to vascular disease, amputations or previous vascular tissue harvesting. Despite the clear clinical needs of vascular substitutes, currently available synthetic grafts (for example, Dacron and Teflon) have proven to be successful only in large calibre implants; small diameter vascular substitutes (<6 mm) have generally unsatisfactory results, with major negative side effects, such as acute thrombosis, hyperplasia and aneurysm [2]. Arterial failures are generally attributed to the relatively low blood flow rate in these small vessels, which increases the rate of interactions between cells and molecules in the blood and polymeric implants. Therefore, there are strict requirements regarding the biofunctionality of the small diameter designed grafts. In order to produce grafts with normal vascular functions, at least 2 requirements must be met: (1) there is a confluent endothelium providing a nontrombogenic interface and (2) there is smooth contractile muscle tissue that can withstand haemodynamic stress and local changes in blood pressure that occur through constriction and physiological relaxation of the vessel [3]. Tissue engineering has emerged as a promising alternative approach for viable small diameter arterial grafts. Various strategies including decellularized tissue, synthetic polymeric matrices, self-assembling cell layers and hydrogels have been used to create living vascular structures and replace native blood vessels; these strategies have achieved different levels of success. These approaches generally produce vascular substitutes in the form of a robust tubular matrix containing smooth vascular or fibroblast muscle cells followed by seeding and cultivation of endothelial cells to achieve endothelialisation. This multi-step construction process is slow and requires complicated procedures and long manufacturing periods. In addition, grafting and retention rate of endothelial cells is strongly influenced by seeding mode, surface properties, cell density and culture conditions and, therefore, current methods can hardly be considered reliable for generating an intact functional endothelium. Therefore, biomimetic reconstruction of blood vessels through tissue engineering remains a difficult task that requires new construction techniques [4-7]. An important advantage of 3D bioprinting is the ability to build tissue / organ equivalents with a structure as close as possible to the native one. The precise positioning of cell-loaded bioinks simulates the anatomical features of the target tissue / organ, so that as cells proliferate, migrate and differentiate into a biomimetic construct. In particular, coaxial extrusion technique can use various biomaterials for bioprinting resulting in vessel-like structures [8].

For the successful bioprinting of a functional vessel, an essential factor is the bioink used. It must be biocompatible with the different cell types and promote the functionality of the cells and also allow the direct bioprinting of the vessels. While the hydrogels used to create vessels (fibrin, elastin, collagen, fibroin) generally have poor printability, materials suitable for co-extrusion bioprinting (alginate, gelatine methacryloyl, photopolymerized hyaluronic acid) usually have negative results due to low cellular affinity or poor mechanical properties and the functionality of the tissues is impaired.

The project aims to create vascular structures using collagen and hyaluronic acid hydrogels and endothelial and muscle progenitor cells derived from mesenchymal stem cells isolated from amniotic fluid using 3D bioprinting. Thus, the objectives for 2019 were:

I. "*Realization of the bioprinted vascular structure and investigation of the biocompatibility of EPC and SPC in the presence of the used hydrogels*". These objectives have the following activities:

I.1 *3D bioprinting of vascular structure and assessment of viability and growth of differentiated progenitor cells;*

I.2 *Research on cell proliferation, oxidative stress and phagocytosis*;

I.3 *Analysis of the secretory profile of EPC and SPC incorporated in the hydrogel*.

II. *"Evaluation of the morphology and adhesion capacity of EPC and SPC incorporated in the hydrogel".* This objective is accompanied by the following activities:

II.1 *Analysis of the rearrangements of actin filaments and microtubules by immunofluorescence*;

II.2 *Evaluation of cell morphology by scanning / transmission electron microscopy*.

I.1 3D bioprinting of vascular structure and assessment of viability and growth of differentiated progenitor cells.

Computer-aided design (CAD) software (BioCad, RegenHU, Switzerland) was used to create the 3D vascular model. Bioprinting was performed using a needle with a diameter of 0.2 mm, under pressure of 1.2 bar, speed of 1 mm / sec, creating vascular structures with a diameter of 2.5 mm, the thickness and the height of each layer 0.3 mm, followed by polymerization of each layer for 5 seconds (Fig. 1).

Fig. 1. Bioprinted 3D vascular structure using collagen-hyaluronic acid hydrogel and progenitor cells

For bioprinting, 3 hydrogels were used:

- H0, collagen hydrogel containing 2% collagen, RehenHu (Villaz-St-Pierre, Switzerland)
- H25, H0 hydrogel towhich 25% hyaluronic acid (MW 1-1.6 MDa, 1%) was added
- H50 H0 hydrogel to which 50% hyaluronic acid (MW 1-1.6 MDa, 1%) was added

Mesenchymal stem cells isolated from amniotic fluid (AFSC) were differentiated into endothelial (EPC) and muscle (SPC) progenitor cells using specific culture media and growth factors.

Endothelial differentiation of AFSC was achieved by cultivation in M200 medium supplemented with 10% FBS (fetal bovine serum), 40 ng / ml vascular endothelial growth factor (VEGF), 20 ng / ml insulin growth factor (IGF-1), 10 ng / ml epidermal growth factor (EGF), 10 ng / ml fibroblast growth factor (bFGF), 100 μg / ml penicillin, 100 μg / ml streptomycin and 50 μg / mL neomycin (Merck, Frankfurter, Germany).

Muscle differentiation was performed in M231 medium supplemented with FGF (2 ng / ml), EGF (0.5 ng / ml), heparin (5 ng / ml), IGF (2 pg / ml) and bovine serum albumin (0.2 pg / ml). The cells were maintained in these environments for 4 weeks and passed to reach the subconfluence. Cell cultures were maintained at 37°C with 5% CO_2 and 21% O_2 in a humidified atmosphere.

Viability assessment was performed using the LDH test (ThermoFischer Scientific, USA). This test measures the amount of LDH (lactate dehydrogenase) in the culture medium. LDH is a cytosolic enzyme and its presence in the culture medium demonstrates that the cells were destroyed and released extracellular LDH. Vascular constructs with EPC and SPC cultured for 21 days in DMEM medium were evaluated to determine cell viability at 7 days and 21 days.

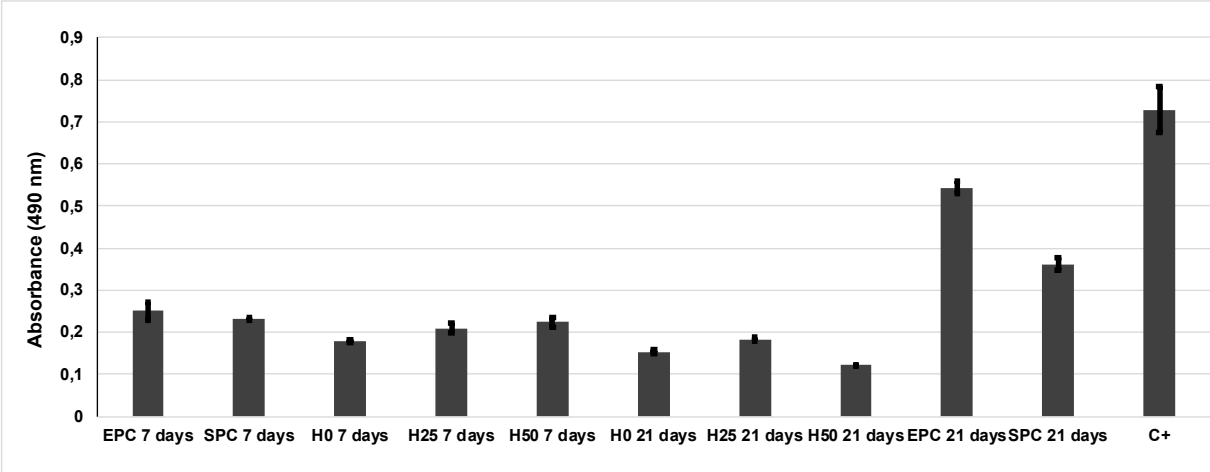


Fig. 2 Assessment of the viability of EPC and SPC in H0, H25 and H50 hydrogels, at 7 and 21 days using LDH assay

The obtained results showed that the cells are viable in the presence of the 3 hydrogels for 21 days. At 21 days EPC and SPC grown in plates without hydrogel (2D system) showed a high level of LDH compared to those in hydrogels, which suggests that collagen-hyaluronic acid hydrogels provide an optimal environment for cell growth (Fig. 2).

I.2 Research on cell proliferation, oxidative stress and phagocytosis

The cellular proliferation of EPC and SPC in hydrogels was investigated using the MTT assay. Based on this quantitative colorimetric method, the proliferation, viability and cytotoxicity of the cell are assessed. The method is based on reducing a yellow MTT tetrazolium salt (3- (4,5-dimethylthiazolyl) -2,5-diphenyltetrazolium bromide) to dark-blue formazan. The reduction achieved by mitochondrial enzymes (especially succinate dehydrogenase) is an indication of cellular / mitochondrial integrity. The insoluble formazan can be solubilized with isopropanol, dimethyl-sulfoxide or other organic solvent. The optical density (DO) of the solubilized formazan is evaluated spectrophotometrically, obtaining a function absorbance-concentration dye-number of metabolically active cells in culture. Vascular constructions grown for 7 days and 21 days, were treated with 15 µl 12 mM MTT and incubated at 37°C for 4 hours. Subsequently, 100 µl SDS-HCl solution was added, and energetically pipetted to solubilize formazan crystals, followed by one-hour incubation. Then pipetted for homogenization and remove all the bubbles to not interfere with reading. The reading was performed at the spectrophotometer at 570 nm (TECAN, Männedorf, Switzerland).

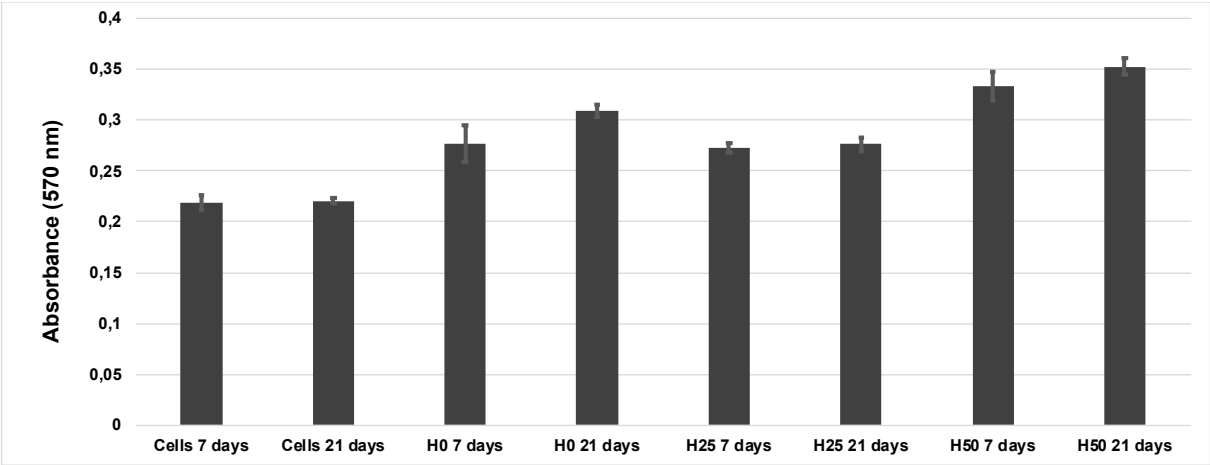

Fig. 3 Evaluation of EPC and SPC proliferation in H0, H25 and H50 hydrogels, at 7days and 21 days using the MTT assay

The results showed that the cells proliferate better in the presence of hydrogels than when grown in culture plates (2D system). In the hydrogel with 50% hyaluronic acid (H50) the most intense proliferation was recorded, both at 7 days and at 21 days. The H0 hydrogel caused an increase in proliferation by 28% at 7 days and 36% at 21 days compared to cells grown in 2D system. The H25 hydrogel allowed cell proliferation for 21 days, resulting in an increase in proliferation by 28% at 7 days and 22% at 21 days compared to cells grown in the 2D system. Hydrogel with 50% H50 hyaluronic acid caused a proliferation of over 57% at 7 days and 59% at 21 days compared with 2D control (Fig. 3).

Oxidative stress assessment was performed using the GHS assay. This kit measures the amount of glutathione, an antioxidant agent. The glutathione produced by the cells is transformed by glutathione S-transferase into oxidized glutathione, the amount of glutathione transformed being directly proportional to the amount of glutathione S-transferase enzyme that transforms glutathione linked with a luciferin precursor into oxidized glutathione linked to luciferin which emits light. The more intense the light, the more glutathione was transformed, so more glutathione was synthesized, so the cell was more stressed. Oxidative stress was assessed using the Glutathione Fluorescent Detection Kit (Invitrogen, ThermoFischer Scientific, USA).

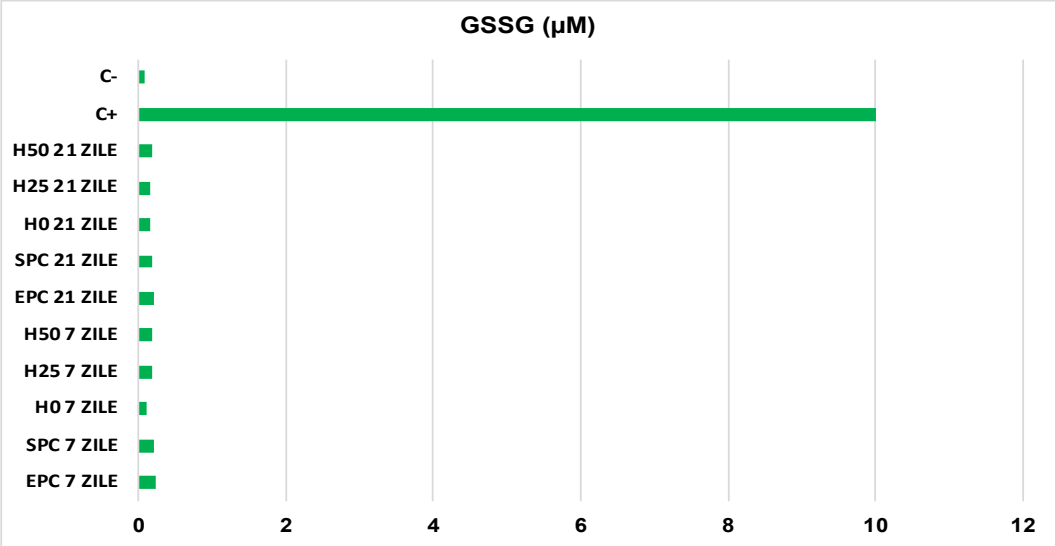

Fig. 4 Assessment of the oxidative stress of EPC and SPC in H0, H25 and H50 hydrogels, at 7 days and 21 days using GSH assay

The results showed that EPC and SPC grown in vascular constructions for 7 days and 21 days are not subjected to major oxidative stress. The highest concentration of oxidized glutathione (GSSG) was in cells grown in 2D system (0.22 µM for EPC and 0.21 µM for SPC). For the H0 hydrogel the GSSG values were 0.11µM and 0.16µM at 7 days and 21 days respectively. The H25 hydrogel recorded GSSG values of 0.18 µM and 0.16 µM, and in the H50 hydrogel the GSSG level was 0.18 µM at 7 days and 0.17 µM at 21 days from cultivation (Fig. 4).

I.3 Analysis of the secretory profile of EPC and SPC incorporated in the hydrogel

In order to demonstrate the ability of EPC and SPC to participate in vascularization, the production of VEGF and nitric oxide in the hydrogels was determined. The production of VEGF was quantified by the ELISA technique and that of nitric oxide using the Griess test.

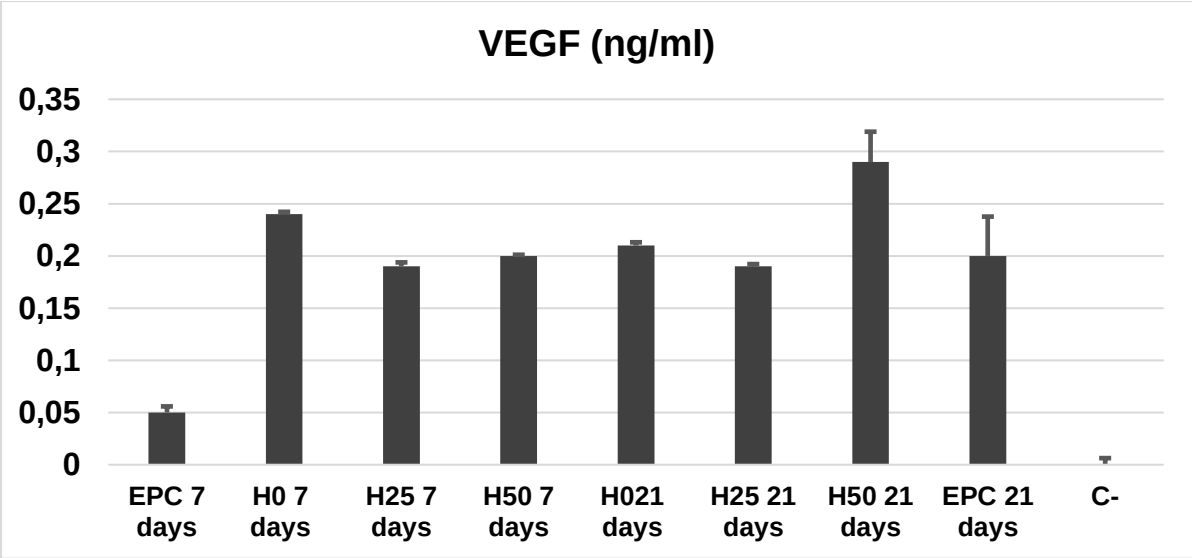

Fig. 5 VEGF concentration (ng/ml) in vascular constructions H0, H25 and H50, at 7 days and 21 days using ELISA assay

The results showed that in vascular constructions the level of VEGF is higher than in 2D system at 7 days. After 21 days of cultivation, the concentration of VEGF in vascular constructs H50 was 0.29 ng / ml, in H25 0.19 ng / ml and in H0 0.21 ng / ml comparable to EPCs raised in 2D system (0.2 ng / ml). Also, the detection of VEGF in the EPC cultures obtained from AFSC shows that the differentiation towards the endothelial line occurred (Fig. 5).

Nitric oxide (NO) is a molecular mediator of many physiological processes, including vasodilation, inflammation, thrombosis, immunity and neurotransmission. There are a number of methods for measuring NO in biological systems. One of these methods involves the use of the Griess diazotization reaction to detect spectrophotometrically the nitrite formed by the spontaneous oxidation of NO under physiological conditions. Detection and quantification of nitric oxide was performed with the Griess Reagent kit (Molecular Probe, ThermoFischer Scientific, USA). The sulphanilic acid is converted into a diazonium salt by reaction with nitrite in acid solution. The diazonium salt is then coupled to N-(1-naphthyl)-ethylenediamine, forming an azo dye that can be spectrophotometrically quantified based on its absorption at 548 nm.

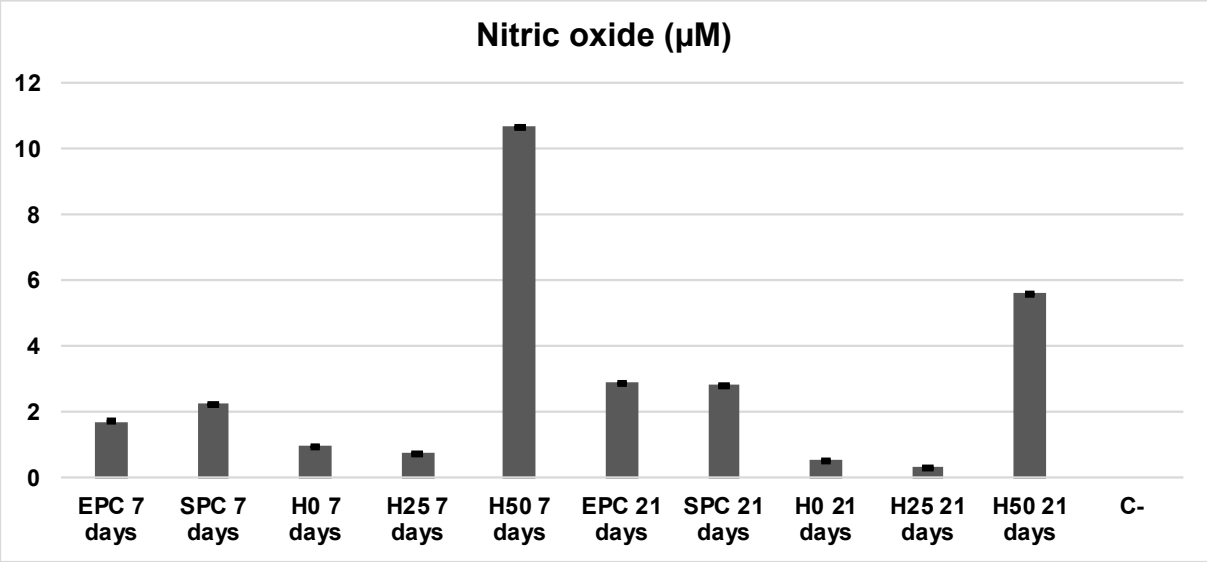

Fig. 6 Assessment of nitric oxide level in H0, H25 and H50 hydrogels, at 7 days and 21 days using the Griess test

Nitric oxide is synthesized by endothelial cells and plays a key role in maintaining vasorelaxation by exerting effects on smooth vascular muscle cells, whose contractile state defines vascular tone. NO produced in the cytosol of endothelial cells diffuses rapidly into adjacent smooth muscle cells, exerting paracrine effects by activating soluble guanylyl-cyclase to increase the synthesis of cyclic 3,5-guanosine monophosphate (cGMP) [9].

NO also decreases cytosolic Ca^{2+} concentration by inhibiting voltage-activated Ca^{2+} channels and activates protein kinases that phosphorylate proteins in the sarcoplasmic reticulum as well as Ca^{2+}-dependent potassium channels. Reduction of cytosolic Ca^{2+} concentration leads to inhibition of the calcium-calmodulin- light chains myosin-kinase complex in smooth muscle vascular cells, favouring vasorelaxation [10].

The obtained results showed that the differentiated cells from AFSC are endothelial progenitor cells because they express VEGF and nitric oxide. The highest amount of NO was identified in the H50 hydrogel reaching values of 10.7 μM and 5.65 μM at 7 days and 21 days respectively. (Fig. 6). EPCs grown in 2D system showed a NO level of 1.74 μM and 2.93 μM at 7 days and 21 days of cultivation (Fig. 6).

II.1 Analysis of the rearrangements of actin filaments and microtubules by immunofluorescence

To create a vascular structure, communication between different cell types is required. These interactions are accomplished through cell junctions, the extracellular matrix and the cytoskeleton. The adhesion of cells occurs through the interactions between the adhesion molecules such as CAMs ("cell adhesion molecules": integrins, selectins, cadherins), the transmembrane proteins located on the surface of the cell and the actin filaments, intermediate filaments and microtubules. Through these cell adhesion processes, cell migration and tissue formation are controlled [11,12]. Integrins are transmembrane receptors that facilitate communication between cells and the extracellular matrix (ECM). When ligand binds to integrins activate signal transmission pathways that mediate a number of cellular processes, such as cell cycle regulation, cytoskeleton organization, and the movement of new receptors to the cell membrane. Integrin ligands include fibronectin, vitronectin, collagen and laminin. Together with the signals from the receptors for soluble growth factors, such as VEGF, EGF, integrins contribute to cellular decisions on biological actions, such as adhesion, movement, death or differentiation. Cell attachment occurs through the formation of cell adhesion complexes, which consist of integrins and many cytoplasmic proteins, such as talin, vinculin, paxillin and act-actinin [13]. Cadherins are $Ca2^{+}$-dependent homophilic glycoproteins. Classical cadherins (endothelial, neural, and platelet) are concentrated at the level of cellular junctions, and they bind to the actin filament network through specific binding proteins called catenins. Selectins are a family of heterophilic proteins that are dependent on fucosylated carbohydrates for binding.

The three members of the family are E-selectin (endothelial), L-selectin (leukocyte) and P-selectin (thrombocyte). Selectins have many roles, but particularly important are those in the immune system, helping in the trafficking and adhesion of leukocytes [14].

Flow cytometry using fluorescent labelled specific antibodies (Gallios, Beckman-Coulter) was used to measure adhesion molecules and cellular interactions. Cells ($1x10^5$ cells / marker) were labelled with fluorochrome-conjugated primary antibodies (FITC - Fluorescein-isothiocyanate and PE - Phycoerythrin) for CD11b (αM integrin), CD29 (β1 integrin), CD31 (PECAM-1), CD44 (HCAM)), CD49e (α5 integrin), CD54 (ICAM-1), CD56 (NCAM), CD73, CD90 (Thy-1), CD105 (endoglin), CD106 (VCAM-1), CD117 (kit-c), CD133 (prominin), CD146 (MCAM), VEGFR1, FOS ALK, and HLA-ABC (Beckman-Coulter). AFSC, EPC and SPC were detached using acutase and washed in phosphate saline (PBS). The cells were then incubated with primary antibodies at room temperature and in the dark for 30 minutes. Further, the cells were washed and centrifuged at 400g, 10 min, in PBS with 1% BSA. For negative controls, cells were stained with isotype IgG antibodies (Beckman-Coulter). Flow cytometry data were analysed using Gallios software (Beckman-Coulter).

Table 1. Results obtained from AFSC and progenitor cells immunophenotyping by flow cytometry

No	MARKER	AFSC	EPC	SPC
1.	CD11b PE (integrin α_M)	4.2%	1.3%	0.08%
2.	CD29 PE (integrin β1)	28%	4%	0.2%
3.	CD31 FITC (PECAM-1)	6.5%	1.3%	0.45%
4.	CD44 FITC (HCAM)	100%	100%	100%
5.	CD49e PE (integrin α5)	100%	99%	94%
6.	CD54 FITC (ICAM-1)	12.5%	25%	5.7%
7.	CD56 PE (NCAM)	13%	38%	1.8%
8.	CD73 FITC	99%	90%	98.5%
9.	CD90 FITC (Thy-1)	97%	95%	100%
10.	CD105 FITC (endoglin)	95.5%	2.5%	1.7%
11.	CD106 PE (VCAM-1)	0%	1.5%	0.14%
12.	CD117 PE (c-kit)	5%	1.7%	0%
13.	CD133 APC (prominin)	5%	1%	0.29%
14.	CD146 PE (MCAM)	98%	70%	2.2%
15.	VEGFR1 PE	7%	3.5%	1.6%
16.	FOS ALK PE	7.5%	3%	3.5%
17.	HLA-ABC PE	100%	1.3%	100%

The results showed that EPC and SPC express CD44 (HCAM) at 100% and CD49e (α5 integrin) at 99% for EPC and 94% for SPC. EPC shows increased expression for the CD54 (25%), CD56 (38%), CD105 (95.5%) markers. Also, markers CD73, CD90, and CD146 are expressed by both EPC and SPC in percentages between 70-100% (Table 1).

II.2 Evaluation of cell morphology by scanning / transmission electron microscopy

Scanning electron microscopy (SEM) was used to observe the behaviour of EPC and SPC in collagen and hyaluronic acid hydrogels. EPC and SPC were homogenized in H0, H25 and H50 hydrogels and bioprinted according to the blood vessel model created in BioCAD. At 7 days and 21 days, constructions were analysed by SEM. They were washed with PBS and fixed in 2.5% glutaraldehyde for 1 hour at room temperature. Then glutaraldehyde was removed and successive dehydration with ethanol (40%, 60%, 70%, 80%, 90% and 100%) was performed for 10 minutes each. The SEM analysis was performed with a HITACHI S2600N electron microscope, at 25 keV, on samples coated with a thin layer of silver.

The results showed that the cells adhere and distribute evenly in the collagen and hyaluronic acid hydrogels, which demonstrates the biocompatibility of these hydrogels.

The H0 hydrogel has a porous structure, forms large pores with a diameter between 80-150μM, H25 has smaller pores, between 40-120μM and H50 between 80-150 μM. In the presence of the H0 hydrogel, the cells have a fusiform morphology and emit filopods that allow the cells to interact with each other and with the collagen fibres. The H25 and H50 hydrogels allow a good growth of cells, forming a rich extracellular matrix which allows a good adhesion and the possibility of organizing in a tissue (Fig. 7).

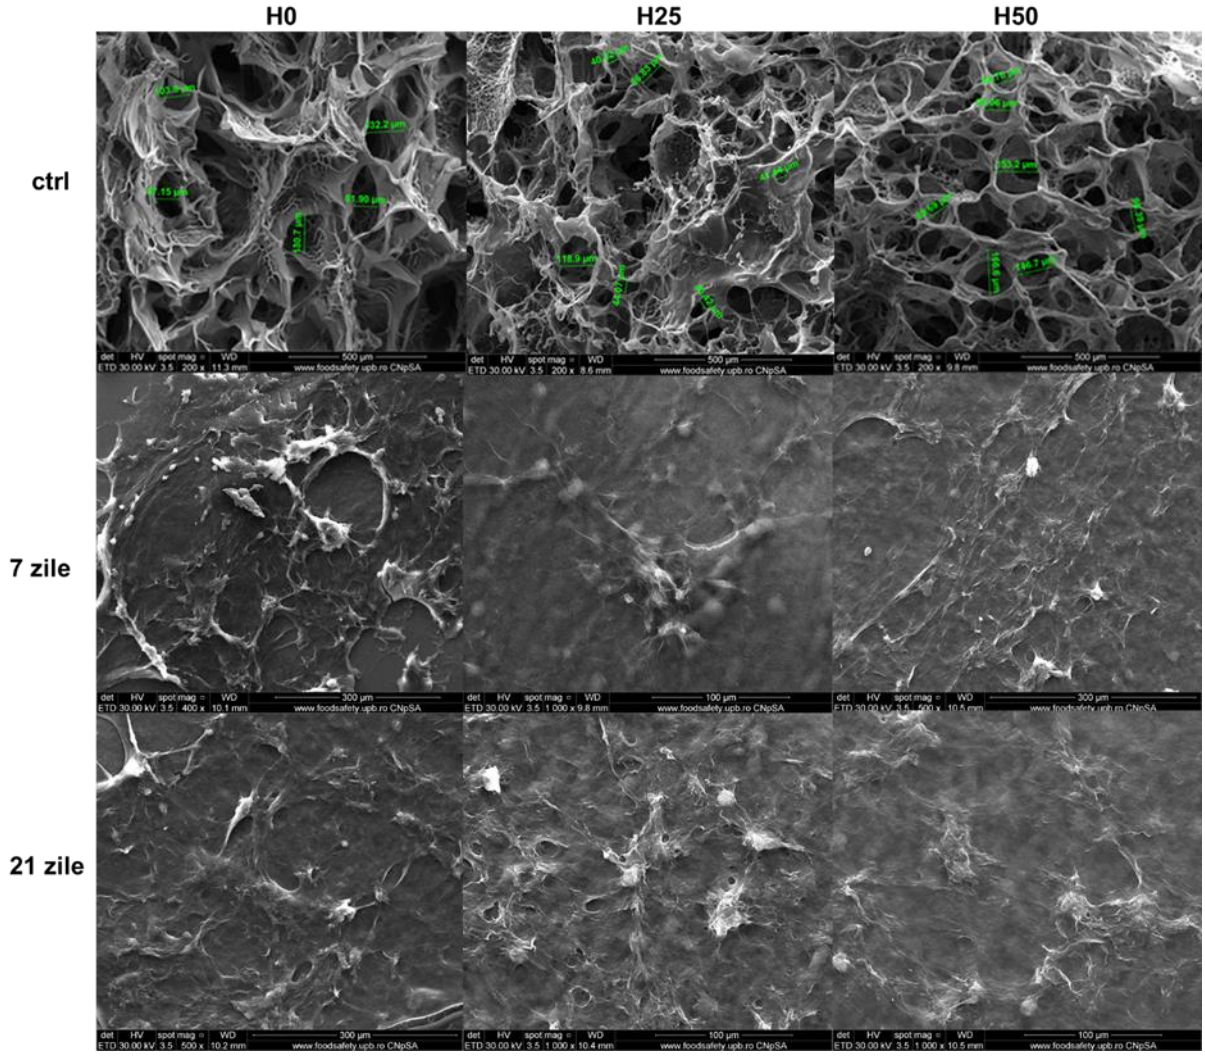

Fig. 7 Scanning electron microscopy images of H0, H25 and H50 hydrogels populated with EPC and SPC at 7 days and 21 days

In conclusion, the collagen-hyaluronic acid hydrogels studied have good biocompatibility. The obtained results showed that in the vascular structures created the cells are viable, proliferating and secreting factors necessary for the formation of blood vessels. The cells in the vascular structures' express markers specific to the endothelial and muscular cells, suggesting the possibility of vascular graft formation. The project will continue with a functional analysis of the vascular structures. Will be analysed functional properties of the vascular structures, by assessing the elasticity, the tensile strength and the contractility.

Mass Spectrometry evidence for modified protein composition of pulmonary lipid rafts in experimental diabetes

Elena Uyy, Viorel-Iulian Suica, Raluca Maria Boteanu, Felicia Antohe, Maya Simionescu

Institute of Cellular Biology and Pathology "Nicolae Simionescu", Bucharest, Romania

Objective

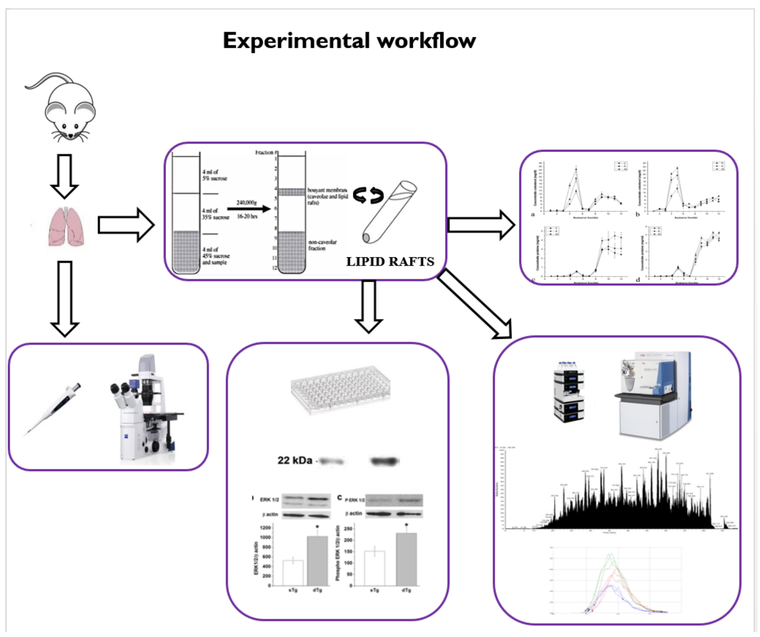
• Diabetes and the associated hyperglycemia affect pulmonary physiology and biochemistry inducing endothelial impairment, as the first step in lung vascular dysfunction. Lipid rafts are involved in signal transduction, cholesterol homeostasis and vesicular trafficking.

•The present study aimed to determine whether lipid raft proteome could be involved in the onset of diabetic state in the pulmonary tissue

•To document the effect of hyperglycemia on lung endothelial cells, we designed experiments on streptozotocin-induced diabetes (sD and their control WT) and on double transgenic diabetic mice (dTg and their control sTg) and investigated (1) the early morphological changes occurring in endothelial cells, (2) the ACE activity and cholesterol content of lipid rafts, and (3) relative protein quantification.

Material and methods

The lungs were harvested, homogenized and lipid rafts, a membrane enriched fraction, were isolated by sucrose gradient ultracentrifugation. Biochemical assays and LC-MS/MS analysis were performed on detergent resistant membrane (lipid rafts) microdomains isolated from the lungs of diabetic and non-diabetic mice. Also, the lungs were investigated by electron microscopy (see the experimental flow design)



Results

CHARACTERIZATION OF ANIMALS

The animals (sD, dTg, WT, sTg) exhibited variations in the body weight and blood glycaemia. The diabetics (sD and dTg) mice lost weight, were short of energy and appetite, and reached pathological blood glucose values. The WT and sTg animals maintained or even gained weight, while presenting a normal blood glucose level (table 1).

Table 1
Characteristics of diabetic and controls mice.

Mice type	WT	sD	sTg	dTg
Body weight (g)	36 ± 1.8	26.83 ± 0.5	25 ± 0.5	16 ± 0.5
Blood glucose (mg/dl)	90 ± 15	265 ± 20	110 ± 1.5	430 ± 2.5

Data are expressed as mean ± SEM.

Electron microscopy results showed a well-developed synthesis apparatus in diabetes, demonstrating high metabolic activity (Fig.3)

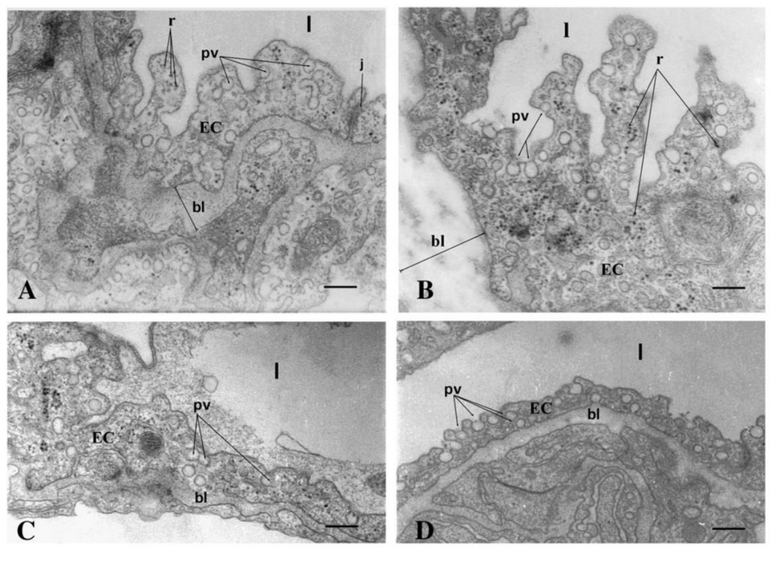


Figure 1. *Note the presence of a highly convoluted apical plasmalemma, the noticeably increased number of plasmalemmal vesicles (caveolae) and ribosomes (r), and the hyperplasic basal lamina (bl) in the double transgenic mice (A, B) vs. (C) single transgenic (D) wild type control mice. pv: plasmalemmal vesicles; I: capillary lumen; EC: endothelial cell; j: junction. Bars= 200 nm.*

Results

•BIOCHEMICAL AND MASS SPECTROMETRIC CHARACTERIZATION OF LIPID RAFTS

• ACE activity and cholesterol concentrations in the fractions obtained after ultracentrifugation of lung homogenate

Tissues from streptozotocin-induced diabetic mice (sD), wild type mice (WT), double transgenic diabetic mice (dTg) and single-transgenic non-diabetic controls (sTg) were homogenized in a buffer containing Triton X-100 and separated on sucrose gradient as describe in materials and methods. ACE enzymatic activity (Fig.2) and cholesterol concentrations (Fig. 3) was measured in the fractions collected after ultracentrifugation of lung homogenate. Also, caveolin-1 expression (Fig. 3: A and B) was investigated by Western blots and densitometric analysis in fraction 4-6 from controls mice (WT) vs. streptozotocin–induced diabetic mice (sD) and single transgenic mice (sTg) vs. double transgenic mice (dTg).

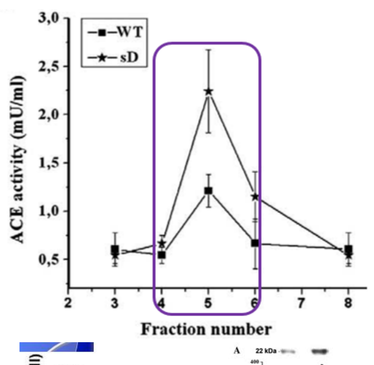

Figure 2 *- ACE enzymatic activity measured in the sucrose gradient separated lung fractions. Note that the ACE activity was 2 times higher in diabetic condition than in the control probes in the lipid rafts enriched membrane fractions 4-6.*

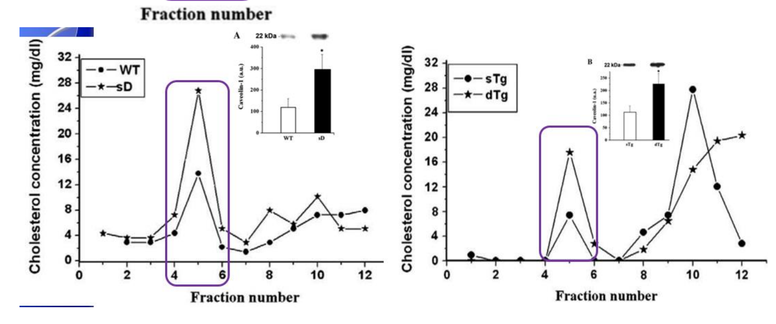

Figure 3 *. The cholesterol concentrations assayed in the 12 collected fractions revealed that in all cases fractions 4-6 (the lipid raft-enriched membrane fraction) present high cholesterol concentration. Note the significantly increased level of cholesterol in diabetic mice.*

• Global Comparative Shotgun Proteomic Analysis

LC-MS/MS experiments performed on lipid rafts enriched membrane fractions isolated from dTg and sTg lung tissue led to the identification of a large number of proteins (1748 proteins) (Fig. 4A)

The relative quantification of the proteins evidenced a total of 88 proteins showing up-regulated abundance (1.5 fold increase of dTg/sTg ratio) while 90 proteins presented down-regulated expressions (0.67 fold lower of dTg/sTg ratio) (Fig. 4C). The post-filtering PCA revealed the excellent differentiation of the dTg and sTg groups. The Protein Center bioinformatics platform was used to identify relevant biological events from the complex data sets. 13 inter-relation maps were found to be over-represented (FDR p value < 0.05 for dTg/sTg) in lipid rafts-enriched membrane fraction isolated from lung tissue (Fig. 4D)

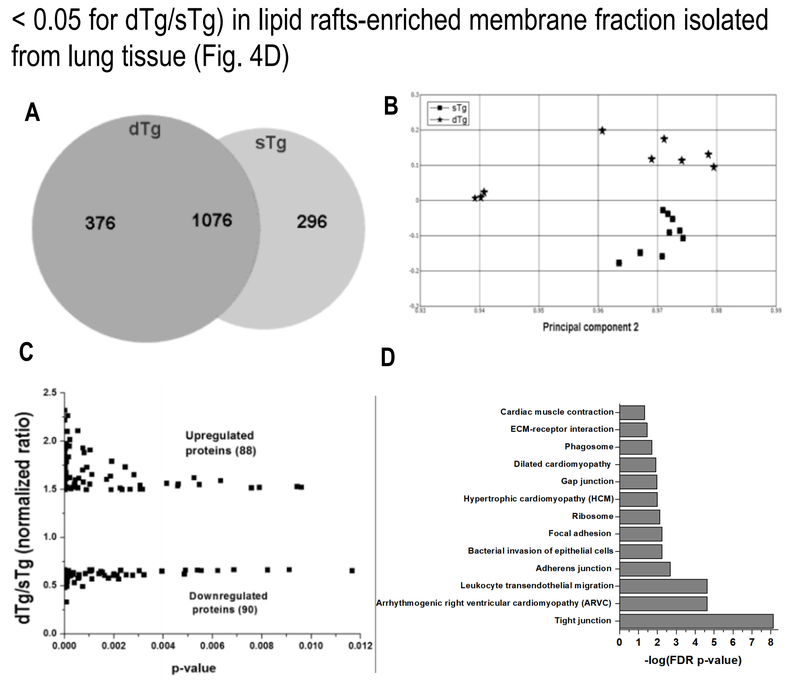

Figure 4. *Characterization of isolated DRMs. (a) Venn diagram of the MS identified proteins in DRMs (fractions 4-6) representing merged experiments from all the technical and biological replicates of the diabetic (dTg) versus control tissue (sTg). (b) Principal Component Analysis of filtered peptides isolated from dTg versus their sTg mice showing the biological significant differences between the two groups. d) The up- and down-regulated ribosomal proteins normalized to the total ion current per MS experiment shown as dTg/sTg ratio. (D)* Over-represented KEGG pathway maps found to be significant (FDR p value < 0.05) statistical over-representation against the mouse database.

Results

- **Ribosomal regulatory proteins in diabetes**.

The list of differentially abundant proteins was correlated with KEGG databases and the Ribosome signaling pathway was found to be systematically over-represented (FDR p-value = 2.66E-4). Within this pathway, the abundance of eight ribosomal proteins was found to be altered in dTg animals, that were statistically up or down regulated in dTg samples versus sTg (Fig. 5B).

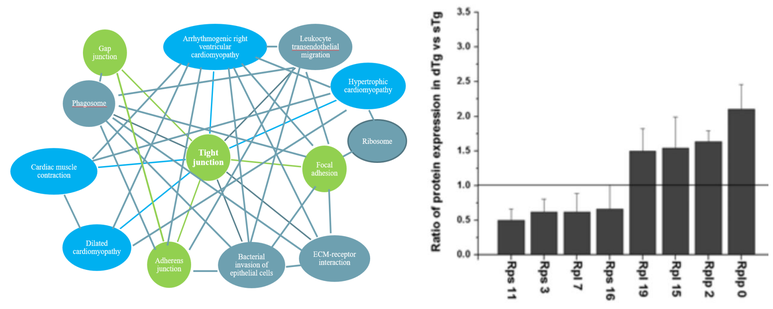

Figure 5*. A. Analysis of pathway crosstalk based on protein-protein interaction networks. The circles indicate the pathways and the lines indicate the links between any two pathways. B. Expression of quantified ribosomal proteins shown as normalized ratio of dTg/sTg.*

- **Mass Spectrometry quantification of alarmins abundance in diabetes**

LC-MS/MS analysis revealed that hyperglycemia has a modulatory effect on the expression of alarmin proteins that co-fractionated with lipid rafts.

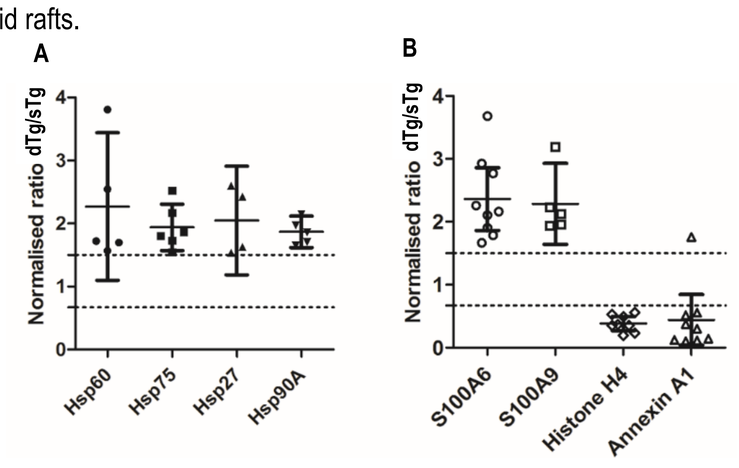

Figure 6. Differential abundance of alarmins in lipid raft enriched membrane isolated from genetically induced diabetic mice (dTg) relative to the control group (sTg). Four members of the HSP (A) and two of the S100 (B) families were clearly more abundant in the diabetic animals than in the control group. Note the statistically significant decreased abundance of the Histone H4 and Annexin A1 proteins (B). The means of the relative ratio of diabetic (dTg) over control (sTg) were calculated in GraphPad Prism with 95% confidence intervals.

Discussion

In diabetic lung, the endothelial cells exhibit both structural and biochemical modifications accompanied by enhanced cholesterol content and ACE enzymatic activity. In adition, mass spectrometry experiments showed a modified expression of caveolin-1, alarmins, ribosomal and junctions proteins associated with lipid rafts. This may point out toward a possible novel regulatory pathways in the mechanism of microangiopathy installation modulated by the lipid rafts composition in the diabetic lung.

Acknowledgements

•We thank Radu Dorel Lucian, M.D., Ph.D., Associate Professor from "Cantacuzino" National Institute of Research and Development for Microbiology and Immunology, Bucharest, Romania for the transgenic-induced diabetes mice, Madalina Oppermann, Ph.D, for valuable collaboration. We thank Dr. D. Popov for the streptozotocin-induced diabetes mice, Mrs. Mariana Pascu for excellent technical assistance and Mrs. Misici Marilena for tissue sectioning. INTRODUCTION

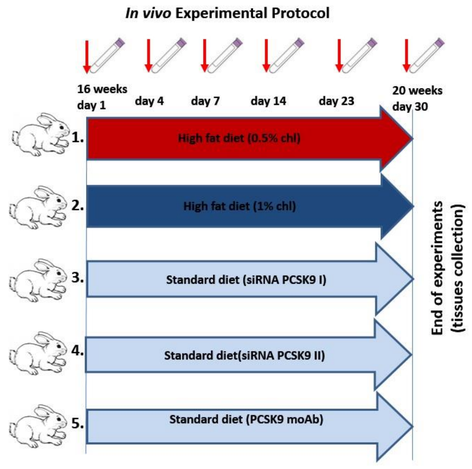
Background. Atherosclerosis is a lipoprotein-driven disease that leads to plaque formation at specific sites of the arterial tree through intimal inflammation, fibrosis, necrosis, and calcification. Sometimes such plaques may suddenly cause life-threatening coronary thrombosis clinically described as acute coronary syndrome.

Hypothesis. An atherosclerotic rabbit model, with a lipoprotein metabolism similar to the human patient, have been proposed to explore the mechanisms leading to plaque instability. We expect to identify an unambiguous alarmin expression pattern, associated to specific atherogenic signalling pathways that may explain the residual risk of cardiovascular-related events and associated mortality.

Aim. The project will explore the plaque instability and the early signs of risks and/or protective factors in coronary disease by using an experimental design comprising both the classical pharmacology (statin administration) and the newest generation of molecular biology approaches (RNA silencing or biological active agents such as PCSK9 antibodies). In preliminary studies the hypercholesterolemic food concentration and treatment to be used was evaluated.

METHODS

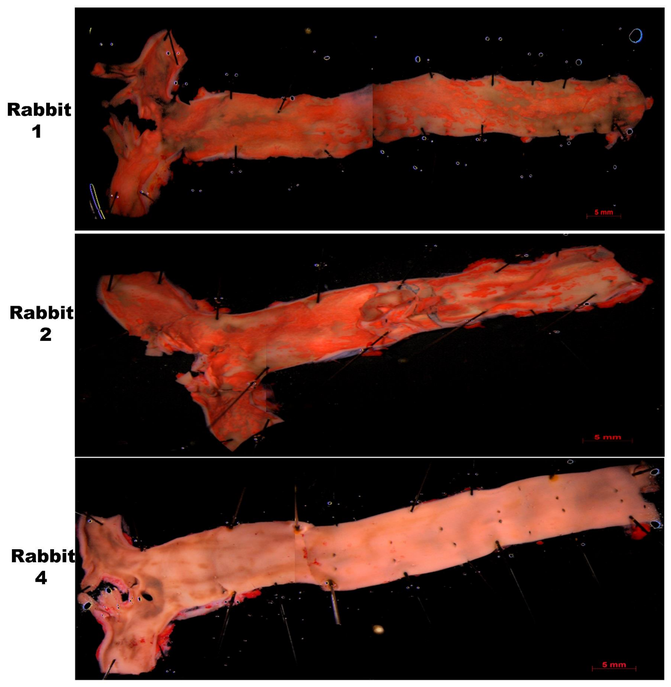


A schematic of experimental design

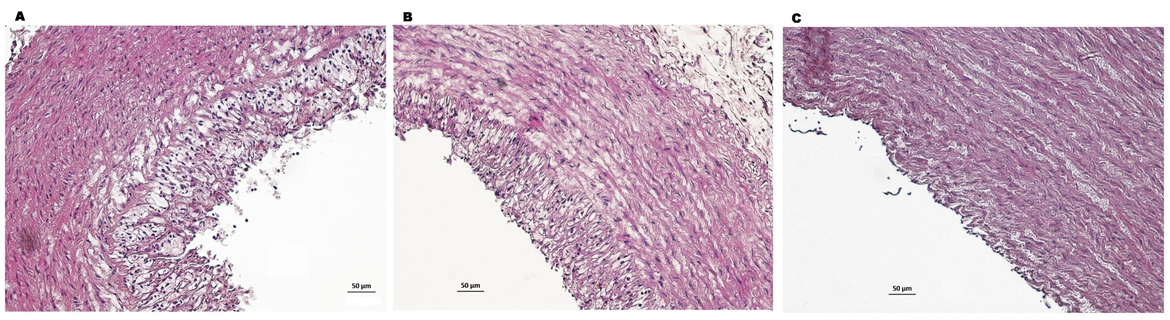
Adult male New Zeeland White rabbits (16 weeks-old) were randomly split into 5 groups: two animals were fed a diet containing either 0.5% or 1% high cholesterol diet and three animals were fed a standard diet together with inhibition of PCSK9 for 4 weeks. The inhibition of PCSK9 were obtained either with siRNA (molecule I or II) or using monoclonal antibodies against PCSK9 (Evolocumab, Repatha, AMGEN).

RESULTS

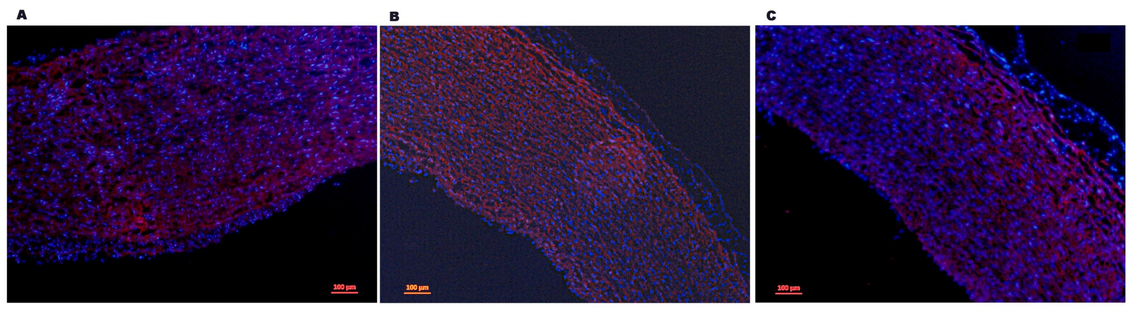
Hyperlipidemic diet induces atherosclerotic plaque progression



The presence of atherosclerotic lesions were assessed by Oil Red O staining. Representative images of aortic atherosclerosis in cholesterol-fed rabbits (rabbit 1 and rabbit 2), comparative with rabbit 4 that were fed a standard diet.

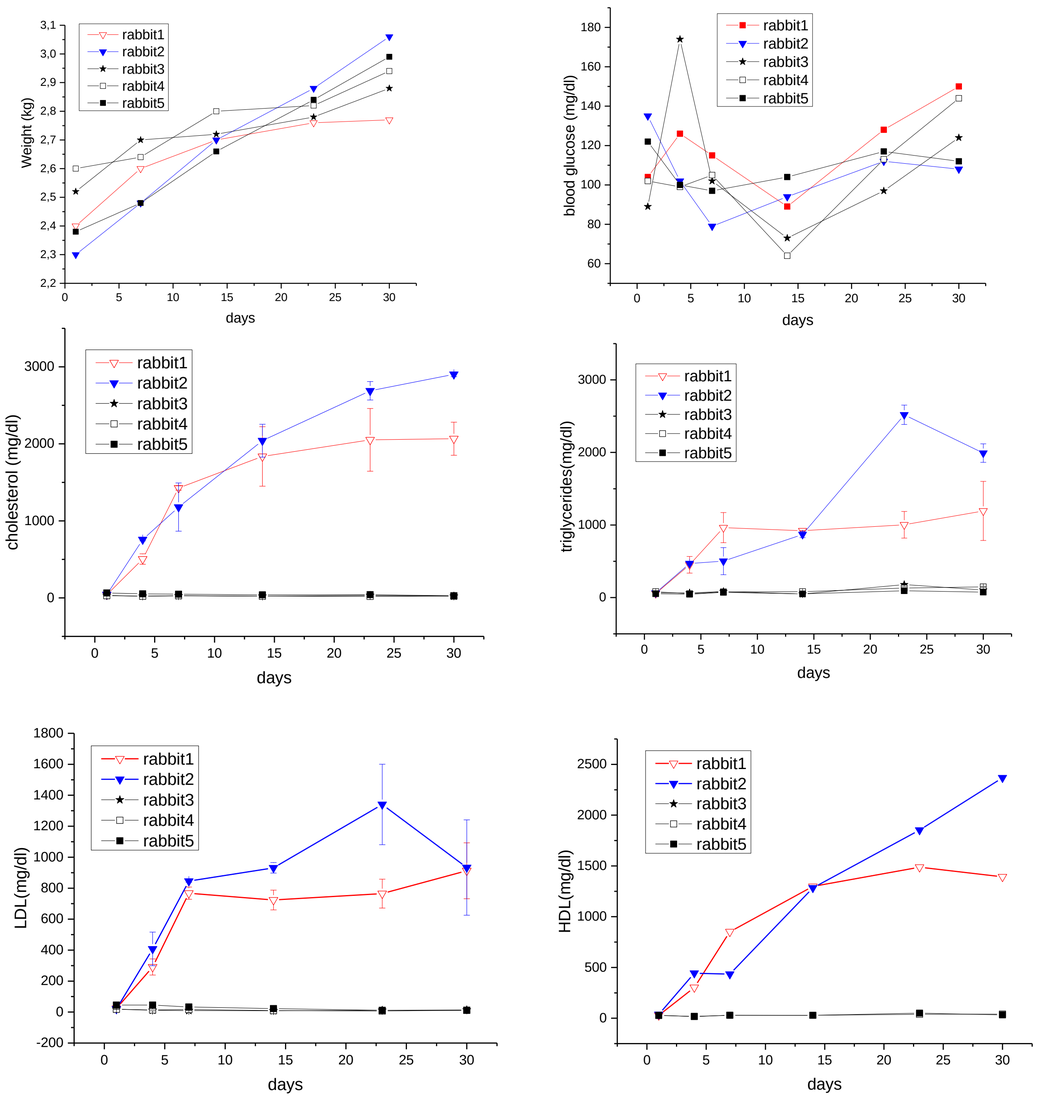


Microscopically atherosclerotic lesions. The presence of atherosclerotic lesions were assessed by hematoxylin and eosin staining, that is essential to evaluate the quality of the lesions (A, B) such as cellular and extracellular matrix component features and plaque vulnerability.

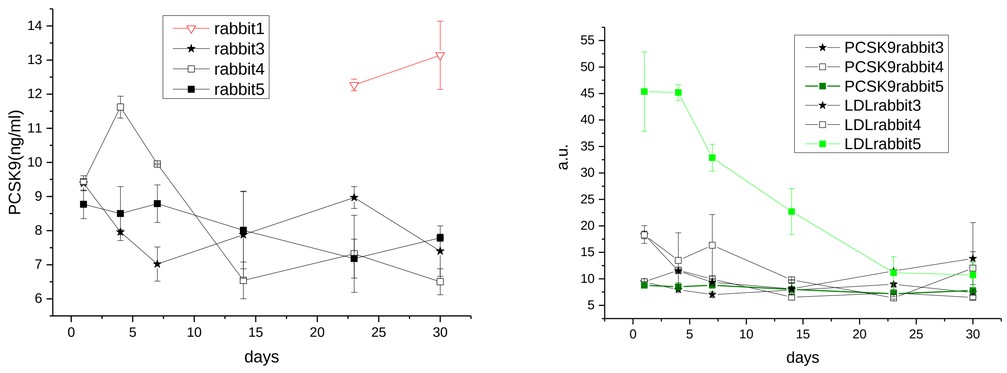


Immunohistochemical investigations of the lesions. In the present study, we found that irrespective of the cholesterol concentration diet the atherosclerotic plaques (A, B) higher expression of α-smooth muscle actin were detected than in the animals fed a standard diet (C).

Hyperlipidemic diet induces a significant increase in lipid parameters in the plasma



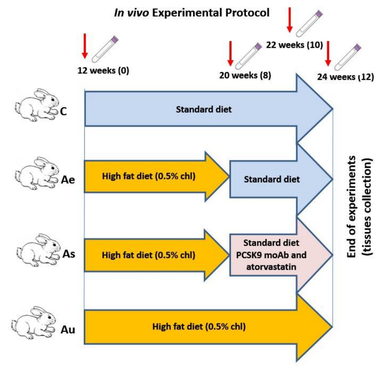
Body weight, blood glucose and plasma lipid profiles. Total cholesterol (TC), low-density lipoprotein cholesterol (LDL), and triglyceride levels were measured by using Dialab kits.



Levels of PCSK9 protein in plasma samples were detected by ELISA kit. The administration of anti PCSK9 antibody showed a decrease of the plasma PCSK9 protein and LDL in the treated animals.

CONCLUSIONS

The preliminary results suggest that hypercholesterolemic diet induces atherosclerotic plaque progression in rabbit model and for more advanced lesions, the 0.5% cholesterol diet will be extended to 12 weeks. The inhibition with anti PCSK9 demonstrated to be functioning in the decreasing of LDL plasma and could be successfully used in the proposed study.



Acknowledgments. The work was supported by the Romanian Academy and Ministry of Research and Innovation grant UEFISCI no. 41/2018.

Prezentare Proiect CARDIOPRO

Institutul de Biologie si Patologie Celulara “Nicolae Simionescu” (IBPC-NS) este un centru de cercetare fundamentala al Academiei Romane, cu experienta de 33 de ani in studiul la nivel celular si molecular al sistemului cardiovascular in conditii normale si patologice, cu precadere a maladiilor majore care afecteaza grav societatea moderna: ateroscleroza, diabet, obezitate si disfunctiile neurovasculare.

Scopul proiectului:

Extinderea si modernizarea infrastructurii de cercetare in domeniul cardio-diabetologiei in vederea accelerarii rezultatelor stiintifice si a transferului lor din laborator in clinica - medicina translationala.

Aceasta va contribui la cresterea capacitatii de cercetare a echipei IBPC-NS, cu consecinte in profilaxia si imbunatatirea tratamentului bolilor cardiovasculare cat si asupra nivelului de competitivitate a stiintei Românesti si integrarea in Aria Europeana de Cercetare.

Obiectivele proiectului:

1) **Cresterea calitatii si competitivitatii cercetarii** prin achizitionarea de echipamente noi in vederea introducerii tehnologiilor moderne, competitive pe plan European. Dotarea laboratoarelor a fost facuta astfel incat sa sustina noi directii de cercetare in cardio-diabetologie: lipidomica, proteomica, genomica-transcriptomica si terapie moleculara, patofiziologie si farmacologie, biopatologia si terapia inflamatiei si medicina regenerativa.

2) **Promovarea tehnologiilor de virf** in cercetarea orientata pentru prevenirea si tratarea maladiilor cardiovasculare si diabezitate, cercetare menită să contribuie la modernizarea actului medical si prin aceasta la scaderea incidentei grave a mortalitatii prin boli cardiovasculare.

3) **Integrarea IBPC-NS in Aria Europeana de Cercetare** prin intarirea relatiilor de colaborare existente, nationale si internationale.

4) **Valorificarea integrala si extinderea potentialului uman din IBPC-NS**: atragerea de tineri cercetatori, crearea de noi locuri de munca, reducerea „brain-drain”.

5) **Dezvoltarea institutională** bazata pe strategia de dezvoltare existentă a institutului şi elaborarea unui plan de actiuni pe termen scurt, mediu si lung; profesionalizarea managementului cercetării şi consolidării rolului ştiinței în societate.

Componente principale proiect:

A. Reabilitarea constructiilor si instalatiilor

Reabilitarea structurala a cladirii de laboratoare, termoizolarea cladirii pentru imbunatatirea performantei energetice, modernizarea suprafetelor construite, a tuturor instalatiilor functionale (ventilatii, climatizari, termice, sanitare, electrice curenti tari si slabi) care sa asigure conditiile unei functionări optime a echipamentelor si aparaturii de cercetare, precum si recompartimentari ce au condus la extinderea spatiilor dedicate cercetarii;

B. Dotari cu echipamente de C-D de inalta performanta

Achizitia a peste 150 echipamente si aparate de C-D, si alte dotari de înaltă performanță, la nivelul standardelor de cercetare ale UE, care au intrat in dotarea celor 13 laboratoare noi infiintate si a laboratoarelor existente, in sprijinul noilor directii de cercetare in cardio-diabetologie:

⇨ *Lipidomica*

Sistem complet gaz cromatograf cu autoinjector şi detectori, cuplat cu spectrometru de masă - Agilent Technologies

Cromatograf lichid de înaltă performanță (UHPLC) cu sistem de injecție a probei şi detectori multimod - Agilent Technologies

Sistem pentru cromatografie lichidă rapidă pentru proteine (FPLC), cu detector UV şi colector de fracțiuni - GE Healthcare

Spectrofluorimetru - ABL&E-Jasco

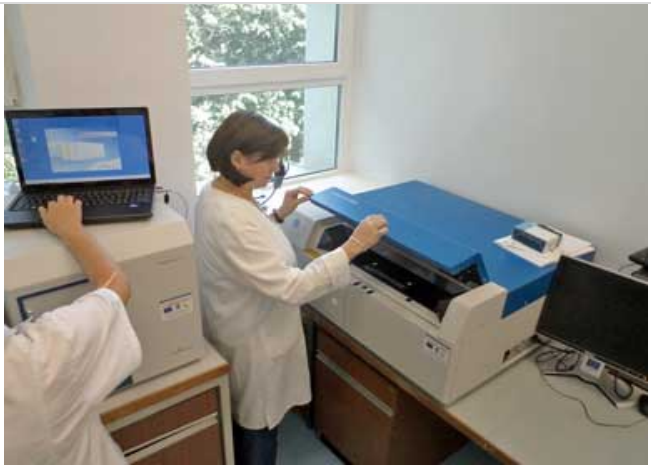
Sistem Real-Time PCR ViiA7 - Applied Biosystems

Aparat pentru preluare imagini in flluorescenta, luminiscenta, UV si vizibil LAS-4000 - GE Healthcare

⇨ Proteomica

Sistem spectrometrie de masa - Thermo Scientific

Spectrofotometru de mare performanta cu capabilitati de fluorescenta si luminiscenta - BMG Labtech



Typhoon FLA 9500 high performance variable mode laser scanner - GE Healthcare

Sistem de nanocromatografie de lichide Easy Nano LC II, Thermo Scientific

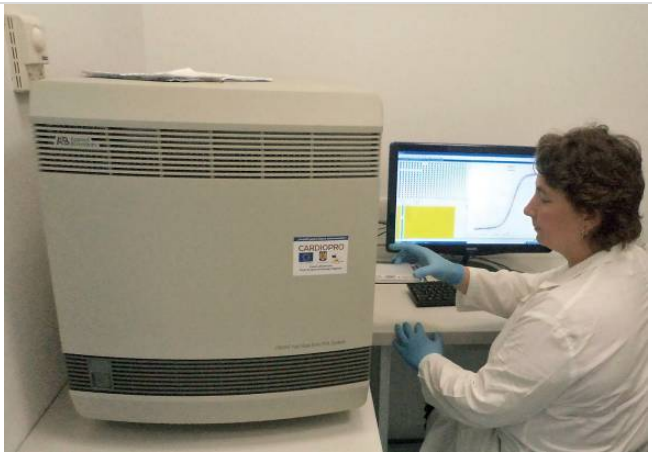
Sistem automat de excizare spoturi - Bio-Rad

Sisteme de mare performanta pentru electroforeza bidimensionala - GE Healthcare / Bio-Rad

⇨ Genomica-transcriptomica si terapie moleculara

Aparat pentru pirosecventiere - Qiagen

Statie de pipetare - Qiagen



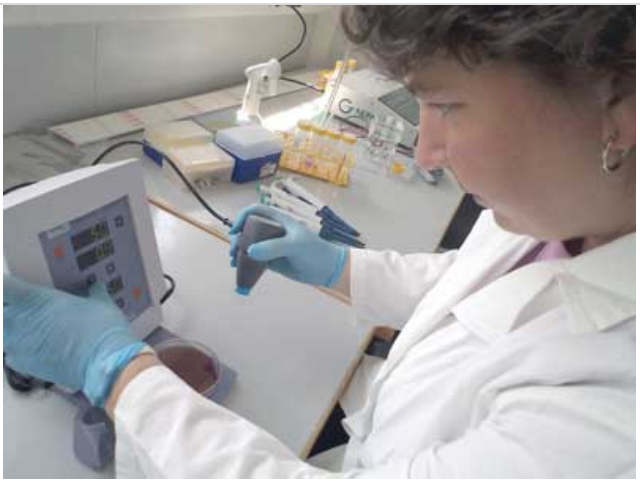
Real Time PCR - Applied Biosystems

Real-time PCR thermocycler LightCycler 480II- Roche

Microscop optic inversat de fluorescenta, Carl Zeiss

Sonicator Bioruptor Plus - Diagenode

Aparat electroporare in vitro si in vivo - NepaGene

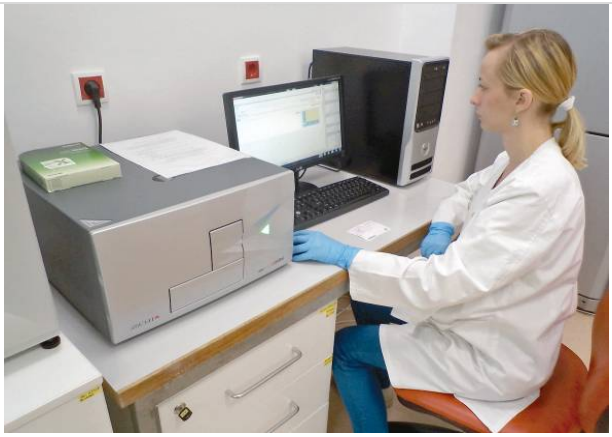


Aparat sonoporare - Sonidel

⇨ *Patofiziologie si farmacologie*

Sistem microdisectie cu laser Zeiss

Echipament complex pentru miografie izometrica - DMT



Spectrofotometru pentru microplaci - TECAN

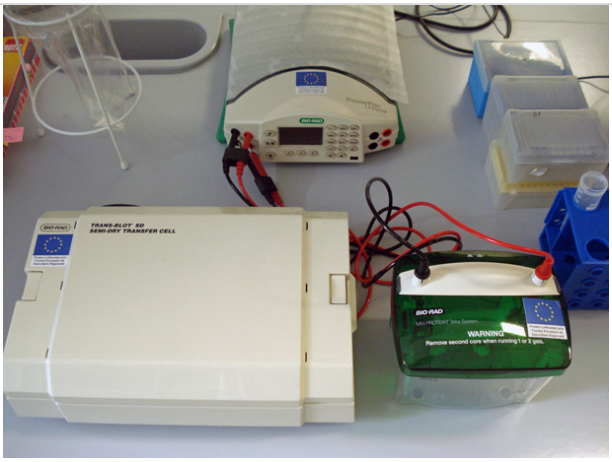
Echipament de PCR conventional (thermocycler) - Applied Biosystems

⇨ *Biopatologia si terapia inflamatiei*

Sistem adeziune in flux laminar - OLYMPUS

Hote cu flux laminar - Euroclone

Centrifuga – Beckman Coulter



Electroforeza, Bio-Rad

⇨ *Medicina regenerativa in terapii celulare*

Citometru de flux - Beckman Coulter

Analizor automat de biochimie, Randox

Microscop inversat - Nikon

Sistem Millar pentru masurarea functiei cardiace prin determinarea concomitenta a presiunii si volumului cardiac

Microscop de fluorescenta, inversat, de cercetare - Zeiss

Vibratom automat - Leica

La acestea adaugandu-se dotarile pentru facilitatile comune departamentelor de cercetare din Institut:

⇨ *IMAGISTICA*

Ultramicrotom EMUC7 cu sistem de sectionare la temperatura joasa EMFC7 - Leica

Sistem confocal - Leica

Ecograf pentru animale mici Vevo 2000- Visualsonic

Sistem tomograf pentru animale mici de laborator IVIS SPECTRUM - Caliper

⇨ LABORATORUL CENTRAL CULTURI CELULARE

Camere curate cu diferite clase de curatenie

⇨ PLATFORMA DE MODELARE EXPERIMENTALA

Rack-uri ventilate cu custi pentru animale mici de laborator, Allentown

Hota biologica de securitate si transfer de animale – ALLENTOWN,
Izolator de transfer mobil 2 manusi - EuroBioConcept

C. Intarirea capacitatii administrative si institutionale

Aceasta componenta a avut in vedere:

- definirea nivelului si rolului Institutului ca actor pe piața internațională a cunoaşterii şi mobilizarea resurselor Institutului de colaborare cu firmele în domeniu;
- introducerea si aplicarea conceptelor privind managementul cercetării;
- practici si metode de valorificare a potentialului de colaborare si participare la rețele naționale şi internaționale, inclusiv acces la instrumente financiare, care să asigure masa critică şi obținerea de rezultate valoroase ale cercetarii la nivel internațional;
- continua evaluare a performanței cercetării.

A fost elaborata Strategia privind dezvoltarea institutionala a IBPC-NS pentru perioada 2012-2015

MERCK

BUN VENIT,

dragi Colegi și Prieteni ai Institutului,

În numele echipei noastre este o plăcere și onoare pentru mine să vă spun:
Bun Venit la această Sărbătoare a IBPC-NS pe care o considerăm o Sărbătoare a Cercetării Românești!

La 40 de ani, fie om, fie Instituție, trebuie să privească deopotrivă, în urmă, în prezent și în viitor. Asta am încercat și noi. Am scos o carte cu amintiri din trecut, am tipărit o carte cu realizări prezente și speranțe de viitor și am organizat acest simpozion în care am invitat Prietenii Institutului, între care, unii prezenți, alții absenți au avut un rol esențial în viața noastră științifică și personală.

Omagiul nostru pentru cei care nu sunt azi cu noi.

Întâlnirea aceasta este o celebrare a șansei noastre de a explora biologia Celulei – pentru că Celula este Viață, este un Univers redus la esență.
Programul este remarcabil și conferențiarii excelenți.

Vă mulțumim că ne sunteți azi alături și sperăm ca acest eveniment să arate încă o dată coeziunea și puternicele legături umane care se pot face prin Știință și pentru Știință.

WELCOME,

dear Colleagues and Friends of our Institute,
On behalf of our team it is a pleasure and honor for me to:
Welcome you to the ICBP-NS Anniversary that we consider as a celebration of Romanian research!

At the age of 40, either a human being or an Institution, must look back, at present, and at the future.
That's what we tried. We brought out a book with memories, we printed a book with present achievements and future hopes and we organized this Anniversary Symposium in which we invited the Friends of the Institute, among which, some present, others absent played an essential role in our scientific and personal life.

Our tribute to those who are not with us today.

This meeting is a celebration of our chance to explore the biology of the Cell - because the Cell is Life, the Cell is a Universe reduced to its essence.
The program of this symposium is excellent and the lecturers outstanding.
Thank you for joining us today and we hope that this event will once again show the cohesion and strong human connections that can be made through Science and for Science.

Bine ați venit în România!/ Welcome to Romania!
Bine ați venit în IBPC!/ Welcome to ICBP!

17.10 -17.25 Mihai Bogdan Preda: "Remote activity of mesenchymal stromal cells in chemical diabetes
17.25 -17.40 Anca Gafencu: "Three killer molecules: engineering adenoviruses for expression of FasL, TNFα and TRAIL"
17.40 -17.50 Mădălina Dumitrescu: "Granting killer properties to mesenchymal stromal cells by FasL-adenoviral transduction"
17.50 -18.00 Violeta Trusca: "The killing capacity of mesenchymal stromal cells -overexpressing TNFα"
18.00 -18.10 Marton Fogarasi: "Design and engineering of TRAIL-expressing mesenchymal stromal cells"

18.10 -19.00 Session III: Lessons from in vivo studies of killer MSC

18.10 -18.25 Mădălina Fenyo: "Immunomodulation of diabetic mice with killer cells"
18.25 -18.35 Ana-Maria Catrina: "Diabetic status determined by islet inflammation and insulin production in immunomodulated diabetic mice"
18.35 -19.00 Discussion

19:30: GALA DINNER

POSTERS: THERAVALDIS PROJECT (19.09.2019)

1) 3D bioprinting model of the aortic valve leaflets
Butoi E., Ciortan L., Iordache F., Macarie R.D., Tucureanu M.M., Alexandru D. Maniu H., Simionescu A., Manduteanu I.

2) Development of a bioprinted 3D model of aortic valve leaflet seeded with human valvular interstitial and endothelial cells
Butoi E., Cecoltan S., Ciortan L., Macarie R.D., Iordache F., Tucureanu M.M., Vadana M., Maniu H., Alexandru D., Simionescu A., Manduteanu I.

3) Constructing of 3D gelatin scaffolds for aortic valve tissue engineering
Butoi E., Cecoltan S., Ciortan L., Macarie R.D., Iordache F., Tucureanu M.M., Vadana M., Maniu H., Alexandru D., Simionescu A., Simionescu M., Manduteanu I.

4) Natural 3D models for tissue engineering of aortic valve
Tucureanu M., Ciortan L., Macarie R., Vadana M., Cecoltan S., Butoi E., Simionescu A., Manduteanu I.

5) Studies on transfection efficiency and toxicity of different nanocarriers of shrna-expressing plasmid on human valvular interstitial cells
Rebleanu D., Constantinescu C.A., Voicu G, Simionescu A., Manduteanu I., Calin M.

6) Establishing Correlations Between Structural and Functional Cardiac Changes and Plasma and Hemodynamic Parameters in Atherosclerosis -Associated Diabetes Mellitus
Alexandru N., Filippi A., Constantinescu C., Frunza S., Tucureanu M., Rebleanu D., Ciortan L., Fenyo M., Simionescu A., Manduteanu I., Georgescu A.

7) High glucose increase pro-osteogenic molecules expression in valvular cells in a 3D model of human aortic valve
Mihaela V., Ciortan L., Macarie R., Tucureanu M., Cecoltan S., Mihaila A.C., Simionescu A., Butoi E., Mânduteanu I.

8) Extracellular matrix remodeling induced by diabetic stimuli in a 3D model of human aortic valve leaflet
Macarie R.D., Cecoltan S., Ciortan L., Simionescu A., Butoi E., Manduteanu I.

9) Number and function of circulating endothelial progenitor cells decline in apolipoprotein E-deficient mice with diabetes and high-fat diet
Filippi A., Alexandru N., Voicu G., Constantinescu C.A., Rebleanu D., Constantin A., Fenyo M., Simionescu D.,Simionescu A., Manduteanu I., Georgescu A.

10) High glucose concentrations and TGF-β1 induce endothelial to mesenchymal transition in valvular endothelial cells
Rebleanu D., Voicu G., Constantinescu C., Ciortan L., Simionescu A., Manduteanu I., Calin M1

11) High glucose concentrations potentiate the induction of osteoblast phenotype of valvular interstitial cells exposed to osteogenic factors
Voicu G., Constantinescu C., Rebleanu D., Simionescu A., Simionescu M., Manduteanu I., Calin M.

12) VCAM-1 targeted nanoparticles are specifically internalized by high glucose-activated valvular endothelial cells cultured in a dynamic 3D bioreactor
Constantinescu C.A., Rebleanu D., Voicu G., Ciortan L., Cecoltan S., Simionescu D., Simionescu A., Manduteanu I., Calin M.

13) Study to establish an optimal model for investigation of diabetes-induced aortic valve disease
Constantinescu C.A., Ciortan L., Rebleanu D., Tucureanu M., Alexandru N., Calin M., Simionescu A., Georgescu A., Manduteanu I.

14) SMAD3 silencing inhibits endmt transition in valvular endothelial cells exposed to high glucose and osteogenic factors

Rebleanu D., Voicu G., Constantinescu C.A., Ciortan L., Macarie R.D., Vadanei M., Simionescu A., Manduteanu I., Calin M.

15) Polyplexes carrying a shRNA plasmid down-regulate the transcription factor runx2 in valvular interstitial cells exposed to high glucose concentrations and osteogenic factors

Voicu G., Constantinescu C.A., Rebleanu D., Simionescu A., Simionescu M., Manduteanu I., Calin M.

POSTERS (20.09.2019)

1) Mesenchymal stromal cells-derived factors improve the colonization of collagen 3D scaffolds with skin cells

Rosca A.M., Tutuianu R., Pruna V., Albu Kaya M.G., Neagu T.P., Lascar I., Simionescu M., Titorencu I.

2) Mesenchymal stromal cells derived exosomes sustain the re-epithelialization process on skin organotypic models

Tutuianu R., Rosca A.M., Pruna V., Lascar I., Neagu P., Simionescu M., Titorencu I.

3) Isolation and characterization of human hypertrophic derived myofibroblasts

Florea G., Iacomi D. M., Radulescu L., Tutuianu R., Pruna V., Rosca A.M., Lascar I., Simionescu M., Titorencu I.

4) Effects of low-dose proton radiation on oxidative stress produced in endothelial and epithelial cells

Mihaila A., Vadana M., Bacalum M., Raileanu M., Ciortan L., Caciun L., Esanu T.R., Manduteanu I., Simionescu M., Butoi E.

5) Generation and characterization of distinct mouse neutrophil subpopulations

Ciortan L., Macarie R., Cecoltan S., Mihaila A., Vadana M., Tucureanu M., Manduteanu I., Simionescu M., Butoi E.

6) Optimization of transfection using fullerene-based nanoparticles for gene therapy purposes

Trusca V.G., Fenyo I.M., Dumitrescu M., Pinteala M., Gafencu A.V.

7) Interleukin-10 signal sequence cloned in front of the luciferase drives the reporter protein secretion

Moise L.G., Tudor L.E., Trusca V.G., Gafencu A.V.

8) The secretory potential of interleukin-10 by the encapsulated endothelial cells

Tudor L.E., Moise L.G., Trusca V.G., Fundueanu G., Bucatariu S., Simionescu M., Gafencu A.V.

9) VCAM-1 targeted flavanone-loaded lipid nanoemulsions exert anti-inflammatory effects on activated endothelial cells

Fuior E.V., Voicu G., Deleanu M., Rebleanu D., Constantinescu C.A., Safciuc F., Simionescu M., Călin M.

10) A new family of vanadium compounds stimulates insulin receptor phosphorylation in HepG2 cells in a time and dose-dependent manner

Cărnuță M.G., Pătrașcu A.A., Maxim C., Anghelache M.F., Mânduțeanu I., Popescu D.L, Călin M.

11) Downregulation of receptor for advanced glycation end products (RAGE) in the aorta of APOE-deficient mice using P-selectin targeted RAGE-shRNA lipoplexes

Constantinescu C.A., Fuior E.V., Rebleanu D., Voicu G., Deleanu M., Tucureanu M, Butoi E., Mânduțeanu I., Escriou V., Simionescu M., Călin M.

12) Development and characterization of an in vitro experimental model of hypertrophic cardiomyocytes of pathological type

Comarita I.K., Constantin A., Alexandru N., Filippi A., Nemecz M., Vilcu A., Procopciuc A., Tanko G., Simionescu M., Georgescu A.

13) Isolation and characterization of mesenchymal stem cells from subcutaneous adipose

tissue and bone marrow from the hamster
Procopciuc A., Comarita I.K., Vilcu A., Filippi A., Alexandru N., Nemecz M., Tanko G., Constantin A., Georgescu A.

14) Study of vascular dysfunction and cardiac hypertrophy in an experimental animal model of atherosclerosis
Vilcu A., Comarita I.K., Procopciuc A., Safciuc F., Alexandru N., Filippi A., Constantin A., Nemcz M., Tanko G., Simionescu M., Georgescu A.

15) Epigenetic regulation of NADPH oxidase 5 expression by histone acetyltransferase-activated mechanisms in human macrophages exposed to inflammatory conditions; potential role in atherosclerosis
Vlad M.L., Manea S.A., Raicu M., Muresian H., Simionescu M., Manea A.

16) Activation of p300 histone acetyltransferase-dependent signaling pathways induces NADPH oxidase expression and oxidative stress in the kidney of diabetic mice
Lazar A.G., Cosac M.T. , Vlad M.L., Raicu M., Manea A., Manea S.A.

17) Murine macrophages proteomic alterations induced by neutrophil secretome using dynamic pulsed SILAC methodology
Suica V.I., Ivan L., Uyy E., Cerveanu-Hogas A., Boteanu R., Butoi E., Manea A., Antohe F., Simionescu M.

18) Alarmins expression in atherosclerotic lesions under severe anti-hyperlipidemic treatment; a mass spectrometry based proteomic approach
Uyy E., Ivan L., Suica V.I., Boteanu R., Hansen R., Antohe F.

19) Proteomic profiling of junctional proteins in HMGB1-stimulated human coronary artery endothelial cells
Boteanu R, Antohe F., Simionescu M.

20) Probiotics administration to hyperlipidemic hamsters modulates microRNAs levels in liver and serum
Niculescu L.S., Dulceanu M.D, Stancu C.S., Carnuta M.G., Barbalata T., Sima A.V.

21) Hyperlipidemia alters the quality of HDL and impedes cholesterol efflux in the small intestine; the effect of ginger extract
Barbalata T., Deleanu M., Carnuta M.G., Niculescu L.S., Sima A.V., Stancu C.S.

22) Human macrophages exposed to aggregated LDL become foam cells, without developing endoplasmic reticulum, oxidative or inflammatory stress
Sanda G.M., Toma L., Stancu C.S., Deleanu M., Moraru O.E., Sima A.V.

23) Influence of aging on the quality and dynamics of mouse cardiac fibroblasts
Rusu E.G., Lupan A. M., Marinescu C., Preda M.B., Burlacu A.

24) MicroRNAs characteristic to fibrosis and hypertrophy are up-regulated during natural cardiac aging
Lupan A. M., Rusu E.G., Marinescu C., Preda M.B., Burlacu A.

25) Hypoxia regulates the pro-angiogenic effect of subcutaneously transplanted mesenchymal stromal cells
Preda M.B., Popescu S., Tutuianu R., Rosca A.M., Simionescu M., Burlacu A.

PROGRAM

INTERNATIONAL CONFERENCE

42nd ANNUAL SCIENTIFIC SESSION

OF THE ROMANIAN SOCIETY FOR CELL BIOLOGY

A hybrid event organized **online** and **onsite**

under the aegis of the Romanian Academy

by

Institute of Cellular Biology and Pathology "Nicolae Simionescu"

Bucharest branch of Romanian Society for Cell Biology (RSCB)

and

Section of Biological Sciences of the Romanian Academy

Dedicated to the Researcher's and Designer's Day

20-21 November 2025

Locations: online (Zoom) and onsite at ICBP "Nicolae Simionescu"

8, Bogdan Petriceicu Hașdeu Street, Bucharest 050568, Romania

Organizing and Scientific Committee

- **Acad. Maya SIMIONESCU**, President of RSCB
- **Dr. Anca V. GAFENCU**, President of Bucharest RSCB Branch
- **Dr. Loredan S. NICULESCU**, General Secretary of RSCB
- **Prof. Cătălina G. PISOSCHI**, President of RSCB Craiova Branch
- **Prof. Tudor C. BADEA**, President of RSCB Brașov Branch
- **Assoc. Prof. Vlad-Alexandru TOMA**, President of RSCB Cluj Branch
- **Prof. Anca HERMENEAN**, President of RSCB Arad Branch

Motto: Together we can find ideas... and good ideas change the world

Dear Colleagues,

We are delighted to invite you to attend the upcoming International Conference, **the 42nd Annual Scientific Session of the Romanian Society for Cell Biology** (RSCB) held under the auspices of the Romanian Academy.

The Conference is dedicated to "the Researchers and Designer's Day".

The event will take place on 20 - 21 November 2025 as a hybrid gathering, both onsite and online, and will be hosted in the Aula George Palade of ICBP-NS.

The conference is intended to be a celebration of our everlasting desire to understand the wonders of the nature, outside and within us, and to share ideas, experiences, get inspiration and build bridges between fields and generations of researchers.

The program includes 10 scientific sessions comprising

- Keynote lectures
- Round Table on *Pathophysiology and Molecular Interactions*
- Round Table on *Modulation of chronic inflammatory response polarization and amplitude by a vertebrate-specific gene: RGC-32*
- Round Table on *Omics Approaches in Molecular Pathology*
- Young Scientists presentations
- Short Communications (ePosters)
- General Assembly of RSCB members

As shown below, the program covers a large diversity of scientific topics, an expression of the development of cellular and molecular biology nowadays.

This year, there will be presented 25 papers and 15 ePosters by 53 participants.

We are lucky to have in our Society excellent senior scientists and numerous young and talented investigators.

We look forward to your valuable participation and appreciate your time and consideration.

Maya Simionescu

and the Organizing Committee

PROGRAM

Day One – Thursday, 20 November 2025

9:30 - 10:15 Opening session

- **Acad. Maya SIMIONESCU**, President, RSCB
- **Acad. Marius ANDRUH**, Vice-president of the Romanian Academy
- **Book launch event:** *NICOLAE SIMIONESCU – ARHITECTUL ȘCOLII ROMÂNEȘTI DE BIOLOGIE CELULARĂ*, Ion Longin Popescu

10:15 - 10:45 Scientific Session 1

Chair: **Acad. Maya SIMIONESCU**

Keynote lecture

- **Prof. Kyriakos KYPREOS**, ICBP-NS, Bucharest and University of Patras, Greece - *Unmet Cardiovascular Risk beyond LDL-C: Insights into Contributing Factors*

10:45 - 11:00 Coffee break

11:00 - 12:00 Scientific Session 2

Chairs: **Prof. Carmen E. COTRUTZ** and **Assoc. Prof. Vlad-Alexandru TOMA**

Round Table - *Pathophysiology and Molecular Interactions*

- **Darius D. RUS,** Babes-Bolyai University, Cluj-Napoca - *Non-Enzymatic Sugar Association Leads to Structural and Functional Modification in Haemoproteins*
- **Marta ANATOLIE**, Institute of Animal Physiology and Genetics, Czech Academy of Science, Libechov, Czech Republic - *From Endomitosis to Aberrant Chromosome Pairing: Cellular Mechanisms Driving Clonal Reproduction and Male Sterility in Fish Hybrid Complexes*
- **Doinița TEMELIE-OLINICI**, "Grigore T. Popa" University of Medicine and Pharmacy Iași - *The Role of IL-6 in Activating the "Molecular Scar" of Psoriasis*
- **Kriti PATHAK**, Promega GmbH - *NanoLuc® Luciferase: A New Era of Gene and Protein Reporter Technologies*

12:00 - 13:00 Lunch break

13:00 - 14:30 Scientific Session 3

Chairs: **Acad. Anca V. SIMA** and **Dr. Camelia S. STANCU**

Young Scientists Communications

- **Teodora BARBĂLATĂ**, Postdoc, ICBP-NS, Bucharest - *Overexpression of Endogenous Apolipoprotein A-I and Paraoxonase 1 Genes in the Liver of apoE$^{-/-}$ Mice by CRISPR/dCas9: an Approach to Impede Atherosclerosis Progression*
- **Marius MULȚESCU**, Ph.D. student, ICBP-NS, Bucharest - *Human Apolipoprotein A-II Modulates the Mitochondrial Respiration in Endothelial Cells*
- **Mihaela G. TURTOI**, Postdoc, ICBP-NS - *Nanodelivery of Bioactive Natural Products to Inhibit Endothelial-to-Mesenchymal Transition: A Novel Therapeutic Strategy for Atherosclerosis*
- **Ruxandra ANTON**, Ph.D. student, ICBP-NS, Bucharest - *Targeted Nanoparticles for Hsp90 Inhibitors Delivery to Fibrotic Cardiac Tissue*
- **Diana V. UȚĂ**, Ph.D. student, ICBP-NS, Bucharest - *Preliminary Data Evaluating the TLR4 Inhibition as a Strategy to Mitigate Diabetic Foot Syndrome*
- **Paul-Ștefan PANAITESCU**, Ph.D. student, "Iuliu Hatieganu" University of Medicine and Pharmacy Cluj-Napoca - *Effect of Gut Microbiota-Derived Metabolite TMAO on Neurodegeneration, Inflammation, Oxidative Stress and Motor Function in Animal Models of Parkinson's Disease*
- **Răzvan-Geo ANTEMIE**, Ph.D. student, "Iuliu Hatieganu" University of Medicine and Pharmacy Cluj-Napoca - *In Vitro Evaluation of the Antioxidant Activity of Polyphenol Quinazolin-4(3h)-One and Catechol Hydrazinyl-Thiazole Derivatives on a Selection of Cell Lines*
- **Ioana REDNIC**, Ph.D. student, University of Medicine and Pharmacy of Craiova - *Antioxidant and Neuroprotective Perspectives of Some Edible Fruit's Extracts Based on a Comparative Phytochemical Profiling and Bioactivity*
- **Bianca SOCEANU**, Ph.D. student, "Grigore T. Popa" University of Medicine and Pharmacy Iași - *The Role of Bioactive Molecular Components of Human Milk in Regulating Cellular Processes*

14:30 - 14:45 Coffee break

14:45 - 15:30 Scientific Session 4

Chairs: **Prof. Anca HERMENEAN** and **Dr. Anca V. GAFENCU**

Short Communications Session (e-Posters) - Part 1

- **Laura M. DĂIAN** et al., ICBP-NS, Bucharest - *Preliminary Dynamics of β-Cell Adjustment to Reduced Mass and Diet-Related Stress*
- **Elena M. LAMBĂ** et al., ICBP-NS, Bucharest - *Sweet Habits: Shaping Pancreatic β-cell Adaptation*
- **Mădălina DUMITRESCU** et al., ICBP-NS, Bucharest - *Expression of Apolipoprotein E4 by Adenovirus-Mediated Gene Transfer to ApoE Deficient Mice Modulates the Properties of HDL in a Dose Dependent Way*
- **Ioana M. FENYO** et al., ICBP-NS, Bucharest - *Apolipoprotein A1 is involved in glucose homeostasis*
- **Nino MARQUÉ** et al., Institut Agro Rennes-Angers, Rennes, France - *Peroxidase Activity of Hemoglobin Subjected to Glycative Stress by Measuring Peroxidase Activity and Molecular Changes in Hemoproteins in a High-Sugar Concentration Microenvironment*
- **Claudia-Andreea MOLDOVEANU** et al., Babes-Bolyai University, Cluj-Napoca - *Matrix Metalloproteinases as Early Biomarkers in Parkinson's Disease*
- **Mihaela BALAȘ** et al., Faculty of Biology, University of Bucharest - *Exploring the Biological Effects of $EuTiO_2$ Nanoscintillator-Mediated Radio-Photodynamic Therapy in Breast Cancer Cells*

15:30 - 15:45 Coffee break

15:45 - 17:00 Scientific Session 5

Chairs: **Prof. Tudor BADEA** and **Acad. Ileana MÂNDUȚEANU**

Round Table - *Modulation of chronic inflammatory response polarization and amplitude by a vertebrate-specific gene: RGC-32*

- **Tudor BADEA**, Transylvania University Brașov - *Response Gene to Complement 32 - a Modulator of Inflammatory Responses in Mice and Humans*
- **Sonia VLAICU**, University of Maryland School of Medicine, Baltimore, USA - *The Role of Response Gene to Complement-32 in Atherogenesis*
- **Alexandru TATOMIR**, University of Maryland School of Medicine, Baltimore, USA - *RGC-32 as a new factor regulating reactive astrocytosis in neuroinflammation*
- **Horea RUS**, University of Maryland School of Medicine, Baltimore, USA - *RGC-32 is a Biomarker of Disease Activity and Treatment Response in Multiple Sclerosis*

Day Two – Friday, 21 November 2025

9:30 - 10:00 Scientific Session 6

Chair: **Dr. Felicia ANTOHE**

- **Rostyslav BILYY,** ICBP-NS, Bucharest - *Seeing the Invisible: Imaging Neutrophil-Derived ROS in Tumor and Inflammatory Tissues?*

10:00 - 10:20 Scientific Session 7

Chairs: **Dr. Irina TITORENCU** and **Dr. Elena BUTOI**

Short Communications Session (e-Posters) - Part 2

- **Raluca ȚUȚUIANU** et al., ICBP-NS, Bucharest - *Characterization and Biological Assessment of Sturgeon-Derived Collagen Porous Scaffolds for Soft Tissue Engineering*
- **Sergiu-Marian VATAMANU** et al., ICBP-NS, Bucharest - *Establishment and Characterization of Human Gingival Fibroblast Cultures*
- **Ana-Maria ROŞCA** et al., ICBP-NS, Bucharest - *Composites Based on Collagen, Chondroitin Sulfate, and Sage Oil with Potential Use in Dentistry*
- **Daniela-Mădălina GHEȚU** et al., ICBP-NS, Bucharest - *Phenoxazine Counteracts High-Glucose-Induced Alterations of Human Mitochondrial Genes: Results on Cardiac Organoids*

10:20 - 10:30 Coffee break

10:30 - 11:45 Scientific Session 8

Chairs: **Prof. Ioana STREAȚĂ** and **Prof. Cătălina G. PISOSCHI**

Round Table - *Omics Approaches in Molecular Pathology*

- **Ioana STREAȚĂ**, University of Medicine and Pharmacy of Craiova - *Multiomics Assessment in Rare Diseases*
- **Anca-Lelia RIZA** and **Mihai G. NETEA**, University of Medicine and Pharmacy of Craiova - *Functional Genomics in Sepsis*
- **Daniel PIRICI**, University of Medicine and Pharmacy of Craiova - *Water channel aquaporin 4 modulates amyloid deposits and cognitive performance in a transgenic animal model for Alzheimer's disease*
- **Adrian FRANTEA**, University of Medicine and Pharmacy of Craiova - *Dual Transcriptome – Proteome Analysis Reveals Distinct Immune Endotypes in Sepsis*

- **Răzvan PLEȘEA**, University of Medicine and Pharmacy of Craiova - *Genotype and Phenotype Correlations in Breast Cancer - Single Center Experience*

11:45 - 12:00 Coffee break

12:00 - 12:30 Scientific Session 9

Chair: **Acad. Maya SIMIONESCU**

Keynote lecture

- **Prof. Anca D. DOBRIAN**, Department of Biomedical and Translational Sciences, Eastern Virginia Medical School at Old Dominion University, Norfolk, VA USA- *Extracellular Vesicles: from cellular sentinels to mediators of the biology of adversity*

12:30 - 12:50 Scientific Session 10

Chair: **Dr. Manuela CĂLIN**

Short Communications Session (e-Posters) - Part 3

- **Carmen NECULACHI** et al, ICBP-NS, Bucharest - *MiR-210 Deficiency Enhances Pro-Inflammatory Activation and Disrupts M2 Macrophage Differentiation in Murine Models*
- **Cătălina MARINESCU-COLAN** et al., ICBP-NS, Bucharest - *From Cancer to Infarcted Hearts: GLIPR1 as a Detrimental Regulator in Activated Cells*
- **Gabriela TANKO** et al., ICBP-NS, Bucharest - *An R Shiny-Based Platform for Automated Quantitative Analysis of Insulin Granule on Electron Micrographs*
- **Alexandra VÎLCU** et al., ICBP-NS, Bucharest - *Exploring the Role of Mitochondrial Dysfunction in Cardiac Hypertrophy in an Experimental Model of Atherosclerotic Cardiovascular Disease; Evaluation of the Therapeutic Potential of MTP-131*

12:50 - 13:00 Coffee break

13:00 - 13:30 General Assembly of RSCB members

- 2025 Reports of RSCB Branches
- 2025 Financial Report for RSCB
- Proposals for 2026 Scientific Meeting of RSCB
- Varia Topics
- Final Conclusions and Remarks: Presidents of RSCB Branches

ȘCOALA DE VARĂ:

"Nanoparticule inteligente pentru livrarea directionată de compuși bioactivi: preparare, caracterizare si aplicații"

va fi organizata in cadrul proiectului

PN-III-P1-1.2-PCCDI-2017-0697 (INTERA): "**Terapii inteligente pentru boli non-comunicabile, bazate pe eliberarea controlată de compuși farmacologici din celule încapsulate după manipulare genetică sau bionanoparticule vectorizate** (13PCCDI/2018),

sub-proiect INTERA 3: "**Nanobioparticule inteligente concepute pentru vectorizarea compușilor bioactivi în terapia inflamației vasculare**"

in perioada **23-24 mai 2019**, in **Bucuresti**.

Tematica: Progresele înregistrate în domeniul nanotehnologiilor și aplicarea acestora în medicină a dus la apariția nanomedicinei. Formularea agenților terapeutici în nanoparticule determină cresterea eficacității acestora prin livrarea specifică la țesuturile afectate și reducerea efectelor secundare.

Școala de vară va oferi o imagine de ansamblu în folosirea nanoparticulelor inteligente pentru livrarea de compusi bioactivi, acoperind fundamentele formării și stabilității nanoparticulelor organice și anorganice, împreună cu metode de caracterizare a acestora si folosirea lor pentru transportul directionat.

Pe langă cursurile teoretice care vor furniza informații despre diferite tipuri de nanoparticule inteligente, inovatoare pentru livrarea de medicamente, tehnologiile de încapsulare și tehnicile de caracterizare a nanoparticulelor, vor fi o serie de demonstrații practice în laboratoarele Facultatii de Chimie Aplicată și Știința Materialelor, Departamentul Știința și Ingineria Materialelor Oxidice și Nanomateriale, Universitatea POLITEHNICA din București si ale Institutului de Biologie si Patologie Celulara "N.Simionescu" din Bucuresti.

Comitet stiintific de organizare:

Dr. Manuela Calin, IBPC "NS", Bucuresti

Dr. Anca Gafencu, IBPC "NS", Bucuresti

Prof. Anton Ficai, UPB, Bucuresti

Dr. Gheorghe Fundueanu, ICMPP, Iasi

ȘCOALA DE VARĂ:

"Nanoparticule inteligente pentru livrarea directionată de compuși bioactivi: preparare, caracterizare si aplicații"

Program:

23 Mai 2019

LOCATIA: Universitatea POLITEHNICA din București, Facultatea de Chimie Aplicată și Știința Materialelor, Departamentul Știința și Ingineria Materialelor Oxidice și Nanomateriale, **Cladire CAMPUS**, Bulevardul Iuliu Maniu nr. 6.

9:00-12:00 Prezentari teoretice: cladire CAMPUS

9:00-10:00 Obtinerea si caracterizarea nanoparticulelor magnetice; nanoformulari cu polifenoli (Prof. Dr. Ing. Anton Ficai, Conf Dr. Ing. Denisa Ficai)

10:00-11:00 Folosirea nanoparticulelor magnetice ca vectori pentru transportul de compusi bioactivi (Dr. Adrian Fifere, ICMPP)

11:00-11:30: Sinteza și caracterizarea nanoparticulelor magnetice acoperite cu polizaharide **(**Drd. Chim. Cornelia Ioana Ilie, UPB),

11:30-12:00: Nanoparticule de oxid de fier acoperite cu dextran biosintetizat ca platforma pentru transportul polifenolilor (Dr. Anca Petrovici, ICMPP)

12:00-13:00 Masa de pranz – la cantina UPB

13:00-17:00 Demonstrații practice in laboratoare UPB, cladire CAMPUS

● Sinteza nanoparticulelor magnetice utilizand metoda coprecipitarii din solutie (Drd. Chim. Cornelia Ioana Ilie, Dr. Ing. Angela Spoiala),

● Incarcarea nanoparticulelor magnetice cu polifenoli (Drd. Chim. Cornelia Ioana Ilie, Dr. Ing. Angela Spoiala),

● Caracterizarea nanoparticulelor magnetice utilizand metode fizico chimice specific (Drd. Chim. Cornelia Ioana Ilie, Dr. Ing. Angela Spoiala)

24 Mai 2019

LOCATIA: Institutul de Biologie si Patologie Celulara “N.Simionescu”, Str. B.P.Hasdeu nr 8

9:00-12:00 Prezentari teoretice - amfiteatrul G.E. Palade

9:00-10:00 Folosirea nanoparticulelor lipidice pentru transportul directionat de agenti terapeutici la peretele vascular (Dr. Manuela Calin)

10:00-10:30 Tehnici de obtinere si caracterizare a nanoparticulelor lipidice directionate specific (Dr. Daniela Rebleanu)

10:30-11:00 Reducerea activarii endoteliului cu ajutorul nanoemulsiilor lipidice incarcate cu polifenoli (Drd. Elena-Valeria Fuior)

11:00-11:30 Principii de baza in citometria in flux (Dr. Alexandru Filippi)

11:30-12:00 Principii de baza in microscopia de fluorescenta si confocala pentru studiul celulelor stem mezenchimale in vitro si in vivo (Dr. Bogdan Preda)

12:00-13:00 Masa de pranz

13:00-17:00 Demonstrații practice in laboratoare IBPC-NS.

Demonstratiile practice se vor realiza pe 3 grupe, prin rotatie.

- **Grupa 1.** Lab. BioNanoMed: Metode de obtinere si caracterizare a nanoparticulelor lipidice (Drd. EV Fuior, Dr. D. Rebleanu, Drd. CA Constantinescu); Lab. Citometrie in flux: Determinarea eficientei de preluare a nanoparticulelor de catre celule cu ajutorul citometrului de flux (Dr. A. Filippi)
- **Grupa 2.** Lab. Biologia Celulelor Stem: Vizualizarea preluarii nanoparticulelor de catre celulele stem mezenchimale (Dr. B. Preda)
- **Grupa 3.** Lab. Reglare Genica si Terapii moleculare: Modele experimentale: culturi celulare, marcare, inducerea expresiei de proteine reporter sau cu potential terapeutic. Formarea complexelor nanoparticule- ADN si testarea complexarii pe gel de agaroza. (Dr. A. Gafencu, Dr. V. Trusca)

PROIECT PN II PARTENERIATE Adriana Georgescu

Monday, 06 December 2010 22:42 Laboratories - Vascular Dysfunction in Diabetes and Obesity

PROIECT PN II PARTENERIATE

PN2 42138 / 1.10.2009, Dr. Adriana Georgescu

Titlul proiectului:

Raportul dintre microparticulele circulante si celulele endoteliale progenitoare, un nou marker celular al disfunctiilor endoteliale induse de asocierea dintre hipertensiune si hipercolesterolemie; efectul anti-aterosclerotic al irbersartanului

Director proiect: Dr. Adriana Georgescu, cercetator stiintific principal II **-** *Institutul de Biologie si Patologie Celulara „Nicolae Simionescu", Bucuresti* si Postdoctorand - *Institutul de Chimie Macromoleculara „Petru Poni", Iasi*

Proiect finantat de: Unitatea Executiva pentru Finantarea Invatamantului Superior, Cercetarii, Dezvoltarii si Inovarii (UEFISCDI)

Directia de Finantare a Dezvoltarii si Inovarii

Programul: Parteneriate in domenii prioritare

Domeniul: Sanatate

Acronim proiect: MPEPC

Perioada: 2008-2011

Rezumatul proiectului:

Ateroscleroza este o afectiune inflamatorie, in care factori de risc ca, hiperlipidemia, hipertensiunea, diabetul, pot stimula direct sau indirect endoteliul arterial provocand atat disfunctii, cat si lezari celulare. Datorita numarului in crestere al bolilor cardiovasculare, exista un interes deosebit pentru investigarea mecanismelor disfunctiilor endoteliale, cum ar fi intelegerea raportului dintre microparticulele circulante (MPs) si celulele endoteliale progenitoare (EPCs), ce ar putea conduce la noi strategii terapeutice.

Scopul: Studiul propus are ca tinta dezvoltarea unui nou model animal, hamsterul hipertensiv-hipercolesterolemic (HH) in scopul de a explora noi markeri biologici (MPs si EPCs) ai modificarilor structurale si functionale ale arteriolelor, cu potentiale aplicatii in cercetarea clinica si ingrijirea pacientilor. In acest sens, prin utilizarea modelului HH tratat cu irbersartan (HHI), ne vom concentra asupra abordarii unui nou tratament bazat pe capacitatea antagonistului receptorului AT1, irbersartan, de a reduce presiunea sangelui, nivelele de colesterol, nivelele de MPs, de a creste EPCs, dar si de a imbunatatii disfunctiile endoteliale asociate atat hipertensiunii cat si hipercolesterolemiei. Avem in vedere o abordare complexa impreuna cu o echipa de cercetatori proveniti din cercetarea fundamentala si din cea clinica, pentru a evidentia biomarkerii de relevanta in medicina si noi tinte pentru terapie.

Principalele obiective sunt:: (1) Caracterizarea modelelor animale experimentale HH si HHI comparativ cu cel al hamsterilor control (C), respectiv a pacientilor HH si HHI fata de subiectii control (C); (2) Cuantificarea nivelelor de MPs si EPCs circulante in corelatie cu concentratiile plasmatice de glucoza si colesterol, cu alterarile presiunii sangelui arterial si ale ritmului cardiac, atat la animalele investigate cat si la pacienti; (3) Caracteristicile structurale ale peretelui vascular arterial la animale si la pacienti, in corelatie cu nivelele de MPs si EPCs; rolul metaloproteazelor matriceale (MMPs) si a inhibitorilor tisulari ai metaloproteazelor (TIMP); (4) Evaluarea functiei peretelui arterial in relatie cu modificarile structurale si biochimice, la grupele experimentale de animale si pacienti; (5) Efectul MPs si EPCs asupra reactivitatii arteriolelor de rezistenta izolate de la modelele animale; **(**6) Studiul relatiei cauzale directe dintre cresterea eliberarii de MPs, scaderea nivelelor de EPCs si raspunsul inflamator al peretelui vascular arterial, prin investigarea exprimarii proteice a markerilor inflamatori specifici (P-selectina, E-selectina, vWF, TF, IL-6, MCP-1, RANTES, eNOs, VEGF, SDF-1) in hamsteri; (7) Investigarea mecanismelor moleculare prin care MPs

si EPCs influenteaza functia peretelui vascular arterial in grupele de animale studiate; rolul receptorilor AT1 pentru AngII.

Metodele includ: modele animale experimentale, date clinice ale pacientilor, testari biochimice, citometria de flux, microscopia electronica, tehnica miografului izometric, biologia moleculara.

Rezultatele estimate sunt: (1) realizarea unui model animal, care mimeaza afectiunile umane atat din punct de vedere metabolic cat si patofiziologic (cum ar fi lezarile celulare ce apar in ateroscleroza umana); (2) gasirea unor noi biomarkeri ai disfunctiilor endoteliale, ce vor oferi nu numai tinte noi in patofiziologie, ci si oportunitatea clinica de a detecta bolile intr-un stadiu timpuriu, de a cuantifica riscul acestora, si de a aplica terapia adecvata la pacienti.

Implementarea obiectivelor proiectului va creste competenta cercetarii biomedicale, vizibilitatea stiintei romanesti, transpunerea ideilor de la masa de lucru la patul bolnavului si atragerea tinerilor cercetatori catre cercetarea biomedicala. Toate activitatile sunt in concordanta cu obiectivul general al programului 4, Sanatate, tematica de cercetare 4.1.6.; 4.1.1. ; 4.1.3.

Concluzii: Rezultatele studiului vor evidentia o noua provocare in restabilirea homeostaziei peretelui arterial, prin controlul farmacologic al eliberarii MPs si EPCs.

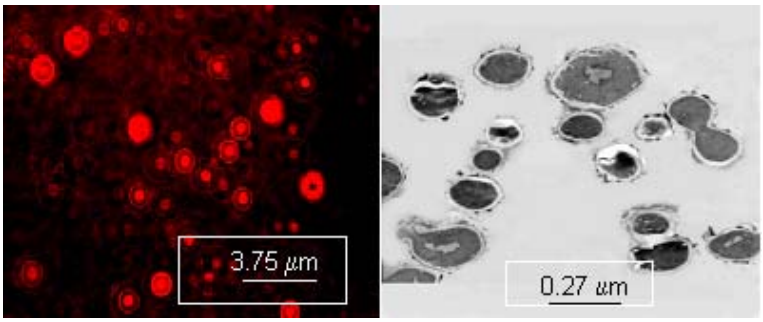
Participantii la realizarea proiectului:

1. Institutul de Biologie şi Patologie Celulară "Nicolae Simionescu" - ***Coordonator***

2. Spitalul Clinic de Urgenta Bucuresti - **Partener 1**

3. Spitalul de Urgenta al M.A.I."Profesor Dr. D. Gerota" – **Partener 2**

Obiectivele generale: Studiul are ca scop: **(1)** dezvoltarea unui nou model animal, hamsterul hipertensiv-hipercolesterolemic (HH), pentru a urmari existenta unei posibile corelatii intre microparticulele circulante (MPs), celulele endoteliale progenitoare (EPCs) si contributia lor la disfunctia vasculara; **(2)** investigarea efectului tratamentului cu irbersartan asupra animalelor HH; **(3)** o abordare complexa a pacientilor HH, pentru a evidentia noi biomarkeri de relevanta in medicina si noi tinte pentru terapie.



Microparticulele circulante

Modul de organizare a proiectului (managementul proiectului): Planul de lucru

Etapa intermediara an 2009

Obiectiv.1. **Caracterizarea modelelor animale experimentale HH si HHI comparativ cu cel al hamsterilor control (C), respectiv a pacientilor HH si HHI fata de subiectii control (C);**

Etapa finala an 2009

Cuantificarea nivelelor de MPs si EPCs circulante in corelatie cu concentratiile plasmatice de glucoza si colesterol, cu alterarile presiunii sangelui arterial si ale ritmului cardiac, atat la animalele investigate cat si la pacienti;

Etapa unica an 2010

Obiectiv 3. Caracteristicile structurale ale peretelui vascular arterial la animale si pacienti, in corelatie cu nivelele de MPs si EPCs; rolul metaloproteazelor matriceale (MMPs si a inhibitorilor tisulari ai metaloproteazelor (TIMP);

Obiectiv 4. Evaluarea functiei peretelui arterial in relatie cu modificarile structurale si biochimice, la grupele experimentale de animale si pacienti;

Etapa unica an 2011

Obiectiv 5. Efectul MPs si EPCs asupra reactivitatii arteriolelor de rezistenta izolate de la modelele animale;

Obiectiv 6: Studiul relatiei cauzale directe dintre cresterea eliberarii de MPs, scaderea nivelelor de EPCs si raspunsul inflamator al peretelui vascular arterial, prin investigarea exprimarii proteice a markerilor inflamatori specifici (P-selectina, E-selectina, vWF, TF, IL-6, MCP-1, RANTES, eNOs, VEGF, SDF-1) in hamsteri;

Obiectiv 7: Investigarea mecanismelor moleculare prin care MPs si EPCs influenteaza functia peretelui vascular arterial in grupele de animale studiate; rolul receptorilor AT1 pentru AngII.

Rezultate obtinute

Rezultate semnificative pentru anul 2009:

Pentru etapa intermediara: **Rezultatul de baza a fost** realizarea unui model animal, care mimeaza afectiunile umane atat din punct de vedere metabolic cat si patofiziologic (cum ar fi lezarile celulare ce apar in ateroscleroza umana). Astfel, am aratat ca dieta cu colesterol, unt si NaCl administrata hamsterilor a fost eficienta in inducerea hipercolesterolemiei si hipertensiunii, modificari obtinandu-se atat la valorile inregistrate la parametri biochimici si tensiune arteriala; cat si la nivelul acumularii de lipide din peretele arterial si arcul aortic. Tratarea hamsterilor hipercolesterolemici-hipertensivi cu irbersartan s-a dovedit a avea efecte benefice, imbunatatind valorile obtinute pentru acesti parametri si de asemenea reducand acumularea de lipide la nivelul arterelor si a arcului aortic asociata cu cei doi factori de risc. In paralel cu modelul animal, au fost selectate si caracterizate loturile de pacienti luate in studiu.

Cunoscand ca ateroscleroza este o afectiune multifactoriala complexa, cu numeroase etiologii, ce actioneaza sinergetic pentru a promova dezvoltarea leziunii, noul model animal hamsterul hipertensiv-hipercolesterolemic(HH), care imita metabolic si patofiziologic afectiunile umane va ajuta la elaborarea de tratamente preventive sau de ameliorare a bolii.

Pentru etapa finala: **Rezultatele** au aratat ca, comparativ cu grupul C, HH a evidentiat o crestere marcata a MPs (EMPs, PMPs, LMPs) si o scadere semnificativa a EPC in corelatie directa cu cresterile semnificative obtinute in concentratiile plasmatice de colesterol si trigliceride, in presiunea sangelui sistolica si diastolica si in ritmul cardiac. In plus, experimentele au aratat potentialul irbersartanului de a corecta toti parametrii alterati in HH.

In concluzie, hipercolesterolemia asociata cu hipertensiunea este acompaniata de cresteri semnificative ale nivelelor plasmatice circulante de MPs (EMPs, PMPs, LMPs) si de reduceri substantiale de EPCs, relatia dintre ele putand fi considerata un marker al disfunctiei vasculare. Irbersartanul, antagonist al receptorului AT1, s-a dovedit a avea un control farmacologic important asupra nivelelor circulante de MPs si EPCs.

Rezultate semnificative pentru anul 2010:

Rezultatele au arata ca: in cazul hamsterilor, comparativ cu grupul control, la grupul HH s-au inregistrat: **(1)** modificari structurale (ingrosarea mediei si a laminei bazale, ingustarea intimei, activarea celulelor endoteliale si a celulelor musculare netede (SMC) si transformarea lor intr-un fenotip secretor, migrarea SMC din media in intima, incarcarea cu lipide a SMC, cresterea numarului de organite celulare, de elemente contractile, acumularea de colagen), ce sugereaza remodelarea vasculara a peretelui arterial; **(2)** prezenta MPs in peretele vascular arterial **(3)** expresie proteica modificata semnificativ a markerilor inflamatori specifici (*MMP-2, MMP-9, MMP-12, TIMP-1, TIMP-2, colagen de tip 1)* cu rol in migrarea SMC, hiperplazia intimei, remodelarea vasculara; **(4)** raspuns contractil redus al arteriolelor la noradrenalina (NA, 10^{-8} – 10^{-4} M), 5-hidroxitriptamina (5-HT, 10^{-8}-10^{-4}M) si potasiu (K^{+}, 24.4 mM, 42.46 mM, 64.1 mM, 83.93 mM, 123.7 mM); **(5)** vasodilatatie dependenta de endoteliu la acetilcolina (ACh, 10^{-8} – 10^{-4} M) si independenta de endoteliu la nitroprusiat de sodiu (SNP, 10^{-8} – 10^{-4} M) drastic reduse. In cazul pacientilor HH, indicele intima-medie si glezna-brat a fost alterat semnificativ comparativ cu acela masurat la subiectii sanatosi. De asemenea, placile de aterom, disfunctia endoteliala sunt prezente la pacientii HH. In plus, experimentele au aratat potentialul irbersartanului de a corecta toti parametrii alterati in HH.

In concluzie, hipercolesterolemia asociata cu hipertensiunea este acompaniata de alterari semnificative ale structurii si functiei peretelui arterial, de inflamatia acestuia, ce se coreleaza cu modificarile parametrilor biochimici, cu cresterile nivelelor plasmatice de MPs circulante (EMPs, PMPs, LMPs) si cu reduceri substantiale de EPCs, relatia dintre ele putand fi considerata un marker al disfunctiei

vasculare. De asemenea, moleculele pro-inflamatorii si MPs din peretele vascular sunt responsabile de aparitia modificarilor functionale la HH, iar tratamentul cu irbersartan, antagonist al receptorului AT1, s-a dovedit a avea un control farmacologic important.

Indicatorii specifici directiei de cercetare 4: Sanatate

Ø **Concepte/studii ale mecanismelor de adaptare ale organismului;**

- Realizarea cu succes a unui model experimental animal.

- Adaptarea hamsterilor la noua dieta alimentara bogata in sare si colesterol.

Ø **Metode pe baze moderne de investigatie in medicina;**

- Stabilirea de noi biomarkeri celulari ai bolilor cardiovasculare si aterosclerozei la pacientii simptomatici si asimptomatici prin citometrie de flux.

- Investigarea tensiunii arteriale (sistolica si diastolica) la animale.

- Stabilirea disfunctiei vasculare la animale utilizand tehnica miografului computerizat.

- Tehnica de imunohistochimie pentru evidentierea unor markeri bilogici in placa atero.

- Tehnica Western Blott pentru cuantificarea epresiiilor proteice a moleculelor inflamatorii.

Ø **Terapii moderne;** metode de preventie si interventionale la nivel naţional, arondate la spaţiul european de operare

-Efectul benefic al irbersartanului (medicament antihipertensiv) in prevenirea si regresia aterosclerozei.

- Rolul pozitiv al EPCs in redresarea disfunctiei vasculare.

Dans le résumé ci-dessous, sont présentés brièvement les objectifs, la méthodologie et les conclusions envisagées sur la base des résultats obtenus des études présentées dans la deuxième partie de la thèse, le chapitre CONTRIBUTIONS ORIGINALES.

But et objectifs

But:

Les études effectuées dans cette thèse visent à rendre compte du rôle et de la manière dont la protéine HMGB1 intervient dans le processus inflammatoire installé dans des conditions hyperlipidémiques – athérosclérotiques et de diabète type 1 expérimentalement induit.

Objectifs:

a. L'analyse de la distribution cellulaire et subcellulaire de la protéine HMGB1 dans le système cardio-pulmonaire soumis au processus inflammatoire déjà existant dans des conditions hyperlipidémiques.

b. La contribution de l'alarmine HMGB1 dans la signalisation cellulaire présente dans l'inflammation induite par le stress hyperlipidémique.

c. L'étude de la protéine HMGB1 dans les macrophages activés par l'incubation au sérum hyperlipémique.

d. L'analyse de la molécule HMGB1 du point de vue génique et protéique à la suite de l'administration du traitement avec fluvastine sodique aux animaux qui ont des plaques athérosclérotiques développées par une diète hyperlipidémique.

e. L'évaluation de l'effet induit par l'administration de la fluvastine sodique sur les protéines de la cascade de signalisation initiée par HMGB1 pendant l'hyperlipidémie induite expérimentalement.

f. L'investigation de la localisation de la protéine HMGB1 dans le tissu pulmonaire soumis à l'hyperglycémie de stress du diabète sucré type 1.

g. La détection des moyens de signalisation activés par l'alarmine HMGB1 dans le pulmonaire diabétique.

- Méthodologie expérimentale

1. Modèles expérimentales
   1.1 Le hamster hyperlipidémique
   1.2 Les souris ayant un diabète type 1 induit expérimentalement
   1.3 Les cultures cellulaires
2. Cryosections
3. Microscopie électronique
4. Déterminations biochimiques
5. La technique ELISA (Enzyme-linked immunosorbent assay)
6. L'extraction de protéines
7. L'électrophorèse SDS-PAGE
8. Technique Western blot
9. L'isolation ARN total
10. Real Time PCR semi-quantitative
11. L'analyse statistique

- Conclusions générales

Les résultats des études effectuées dans cette recherche ont montré que:

1 – La diète hyperlipidémique peut induire la libération de l'alarmine HMGB1 dans le sérum, en lui attribuant le statut de marqueur des événements athérosclérotiques déclenchés ultérieurement par l'état hyperlipidémique.

2 – L'expression génique accrue et le niveau protéique élevé de l'alarmine HMGB1 dans l'extrait protéique qui provient du cœur des animaux hyperlipidémiques , indiquent l'existence du processus inflammatoire au niveau de cet organe.

3 – Le poumon des animaux hyperlipidémiques a montré une croissance de l'expression génique et un niveau élevé de la protéine HMGB1 dans les deux

fractions protéiques subcellulaires analysées, tout en signalant la présence de l'inflammation tissulaire.

4 – La liaison démontrée entre HMGB1 et l'hyperlipidémie expérimentale offre à l'alarmine le statut de cible incontestable de la stratégie thérapeutique utilisée afin d'améliorer l'état clinique du patient et également pour une évolution positive du patient.

5 – Dans le tissu cardiaque et pulmonaire l'expression protéique accrue de la protéine HMGB1 entre en corrélation positive avec le niveau élevé du récepteur RAGE et avec la forte phosphorylation de la kinase AKT. Toutes ces données nous fournissent la possibilité d'affirmer que dans le cas des animaux hyperlipidémiques, l'interaction HMGB1 – RAGE peut maintenir le processus inflammatoire par l'activation du système de signalisation PI3K/ AKT.

6 – Les résultats obtenus apportent des informations nouvelles pour la compréhension des mécanismes qui sont à la base du processus inflammatoire déclenché par les perturbations du métabolisme lipidique et entretenu par la protéine HMGB1.

7 – L'administration de la fluvastine aux animaux qui ont subi au départ une diète hyperlipidémique a eu un effet positif au niveau du tissu cardiaque, effet traduit par l'arrivée de la molécule HMGB1 à un niveau génique semblable à celui détecté sur les animaux cobayes control.

8 – Le traitement avec la fuvastine a eu le même effet positif sur le récepteur RAGE et sur la kinase AKT1 phosphorilates. Ainsi, la conséquence majeure de ces événements moléculaires générés par l'action de la fluvastine est représentée par la diminution de la synthèse de novo des molécules pro-inflammatoires, inclus la RAGE et le HMGB1, ayant comme conséquence la diminution de l'inflammation tissulaire.

9 – Une autre nouveauté que nous avons réussi à démontrer est représentée par la capacité de la fluvastine à réduire de manière significative la concentration sérique de l'alarmine HMGB1.

10 – Nous avons pu enregistrer la diminution de l'expression génique et protéique de la molécule HMGB1, dans le tissu pulmonaire chez les animaux control. Egalement, le niveau du récepteur RAGE et le degré de phosphorylation de la kinase AKT ont été diminués de manière significative, en troublant ainsi l'interaction HMGB1-RAGE et implicitement la signalisation par PI3K/AKT, qui active le facteur de transcription NF-kB. Ainsi, le niveau des cytokines pro-inflammatoires diminuera et le processus inflammatoire perdra également son intensité.

11 – Les expérimentations effectuées apportent des nouvelles preuves qui soutiennent l'hypothèse que l'alarmine HMGB1 fonctionne comme un médiateur de l'inflammation systémique généré pendant le stress hyperlipidémique.

12 – Le modèle expérimental *in vitro* proposé, s'intègre dans la catégorie des modèles utilisés dans l'étude des cellules spumeuses qui sont à l'origine du processus d'athérosclérose.

13 – Le sérum hyperlipidémique induit la translocation de l'alarmine HMGB1 du noyau en cytoplasme, processus démontré par la quantité significativement réduite de HMGB1 dans le noyau mais élevé dans le cytoplasme des macrophages pour qu'à la fin HMGB1 soit sécrétée dans le milieu extracellulaire.

14 – Les résultats obtenus rendent possible l'introduction de la protéine HMGB1 sur la liste de cytokines impliqués dans la pathogénie de l'athérosclérose, tout en ayant en vue sa relocalisation subcellulaire dans les macrophages chargés de lipides ce qui indique le rôle important de l'alarmine HMGB1 des étapes préliminaires au processus athérosclérotique.

15 – Les macrophages activés avec du sérum hyperlipidémique expriment sur leur surface le récepteur RAGE dans une quantité plus considérable que les cellules control. Dans le même contexte hyperlipidémique a été mis en évidence le système de signalisation PI3K/AKT chez les macrophages activés, par la phosphorylation de la kinase AKT à la thréonine de la position 308.

16 – Les résultats de l'étude *in vitro* représentent une preuve incontestable que HMGB1 est un médiateur important de l'inflammation déclenchée par le stress hyperlipidémique et que son blocage pourrait envisager un ralentissement du processus athérogénique.

17 Les animaux doubles transgéniques ont souffert pendant 8 semaines de divers déséquilibres métaboliques et somatiques qui ont conduit à l'installation du diabète sucré type 1, en représentant ainsi, un choix conforme aux exigences de l'expérimentation.

18 – Les modifications biochimiques produites aux animaux dTg, représentées surtout par le niveau glycémique élevé ont généré à ces animaux un manque d'énergie expliqué par le manque de l'insuline qui assure le nécessaire énergétique des cellules. Cet état a amené implicitement à une perte de poids de ces animaux diabétiques.

19 – La morphologie atypique de l'endothélium vasculaire pulmonaire détectée chez les souris dTg et le niveau élevé de la protéine HMGB1 dans le poumon diabétique expliqués par synthèse élevée de HMGB1 et par sa translocation du noyau vers le cytosol, indiquent l'existence du processus inflammatoire au niveau de ce tissu.

20 – Le processus inflammatoire mis en évidence dans le poumon diabétique, est maintenu et par la suite amplifié par les systèmes de signalisation activés par l'alarmine HMGB1. Ainsi, nous n'avons pas signalé seulement le niveau élevé du récepteur RAGE dans le tissu pulmonaire des souris mais aussi, son activation mise en évidence par la phosphorylation de la kinase AKT1 et par le niveau élevé de la sous-unité p65 du facteur de transcription NF-kB. Etant donné le fait que le facteur nucléaire kappa b est impliqué dans la synthèse de novo du récepteur RAGE mais aussi de l'alarmine HMGB1, nous considérons que dans le poumon diabétique est induit un état inflammatoire qui peut acquérir l'ampleur nécessaire afin de produire des modifications histologiques tissulaires et ainsi, d'affecter la fonction pulmonaire.

21 – A la lumière de ces données de même qu'aux implications qu'elles entrainent, des éventuelles thérapies qui ciblent le blocage de l'alarmine HMGB1 pourraient être essentielles dans la diminution des complications cardio-vasculaires associées à l'hyperlipidémie et au diabète.

In this summary, the objectives, methodology and general conclusions based on the results obtained from the studies included in Part II of the paper, the original contributions, are briefly presented.

Aim and objectives

Aim:

To determine the role and how HMGB1 protein acts in the inflammatory process installed in hyperlipidemic - atherosclerosis conditions and diabetes type I induced experimentally.

Objectives:

a. To analyze the cellular and subcellular distribution of HMGB1 protein in cardiopulmonary system under existing inflammatory process in hyperlipidemic conditions.

b. Assess the contribution of alarmin HMGB1 in inflammatory cell signaling induced by hyperlipidemic stress.

c. Study the HMGB1 protein expression in macrophages activated by exposure to hyperlipidemic serum.

d. Examine the gene and protein expression of HMGB1 after treatment with fluvastatin sodium in animals which developed atherosclerotic plaque through hyperlipidemic diet.

e. Evaluate the fluvastatin effect on HMGB1 signaling cascade during experimentally induced hyperlipidemia.

f. Investigate the HMGB1 protein localization in lung tissue under hyperglycemic stress in type 1 diabetes.

g. Detect the signaling pathways activated by HMGB1 in diabetic lung.

Experimental methodology

1. Experimental models
   1.1 Hyperlipidemic hamster
   1.2 Mouse model of type 1 diabetes
   1.3 Cell culture
2. Cryosections
3. Electron microscopy
4. Biochemical analysis
5. Enzyme-linked immunosorbent assay (ELISA)
6. Protein extraction
7. SDS-PAGE Electrophoresis
8. Western blot
9. RNA isolation
10. Quantitative real-time polymerase chain reaction
11. Statistical analysis

General conclusions

Results obtained from the studies achieved in this thesis showed that:

1 – Hyperlipidemia can induce the release of HMGB1 in serum, leading to a situation in which the alarmin HMGB1 acts as a marker of atherosclerotic events that occur after a hyperlipidemic diet.

2 – Increased gene expression and high protein level of alarmin HMGB1 in the heart of hyperlipidemic animal, revealed the existence of the inflammatory process. .

3 – The lung of hyperlipidemic animals showed an increase of HMGB1 gene and protein expression in both subcellular protein fractions analyzed, signaling the presence of tissue inflammation.

4 – The demonstrated link between HMGB1 and experimental hyperlipidemia gives the alarmin a certain target status for therapeutic strategy used to improve the clinical condition for a favorable evolution of the patient.

5 – In the heart and lung tissue, the increased HMGB1 protein expression correlates positively with high levels of RAGE and a strong phosphorylation of AKT. This new data demonstrated for the first time that in hyperlipidaemic animals, HMGB1 - RAGE interaction maintains the inflammatory process by activating PI3K/ AKT signaling pathway.

6 – The results provide new information for understanding the mechanisms underlying inflammatory process triggered by disturbances of lipid metabolism maintained by HMGB1 protein.

7 – Fluvastatin treatment of the animals fed initially with hyperlipidemic diet had a positive impact on cardiac tissue by bringing the expression of HMGB1 gene and protein at a level similar to that detected in control animals.

8 –The fluvastatin treatment had the same positive effect on RAGE and phosphorylated AKT1. Thus, the major consequence of these molecular events generated by the action of fluvastatin is represented by decreasing *de novo* synthesis of pro-inflammatory molecules, including RAGE and HMGB1, having as consequence the reduction of tissue inflammation.

9 – Another element of novelty demonstrated is the ability of fluvastatin to reduce significantly the serum concentrations of alarmin HMGB1.

10 – Gene and protein expression of HMGB1 in lung tissue of treated animals were decreased. Furthermore, RAGE and phosphorylation level of AKT were significantly reduced, which affected HMGB1-RAGE interaction and therefore the PI3K/AKT signaling, which activates the transcription factor NF-kB. Thus, the pro-inflammatory cytokines will fall and with them the inflammatory process will lose its intensity.

11 – The experiments provide further evidence supporting the hypothesis that alarmin HMGB1 acts as a mediator of systemic inflammatory stress generated during hyperlipidemia.

12 – The *in vitro* experimental model proposed fits to the category of models used in the study of foam cells, a cell population present mainly within atherosclerotic lesions.

13 – The hyperlipidemic serum induce HMGB1 translocation from the nucleus into the cytoplasm, a process demonstrated by the significantly reduced amount of HMGB1 in the nucleus, but increased in the cytosol of macrophages, and finally secreted in the extracellular environment.

14 – The results make possible the introduction of HMGB1 on cytokines list involved in the pathogenesis of atherosclerosis; its subcellular relocation in macrophages loaded with lipids, indicating the existence of an important role of alarmin HMGB1 since the early stages of atherosclerosis.

15 – Macrophages activated with hyperlipidemic serum expressed on their surface RAGE in a higher quantity than control cells. In this hyperlipidemic context, the activation of PI3K/AKT signaling pathway was proved in activated macrophages by AKT phosphorylation on threonine 308.

16 – *In vitro* findings are clear evidence that HMGB1 is an important mediator of inflammation triggered by hyperlipidemic stress; blocking the HMGB1 release could be a feasible method to slow the atherosclerotic process.

17 – Double transgenic animals suffered during eight weeks various metabolic and somatic disorders leading to the onset of diabetes type 1, representing a choice conform to the requirements of the experiment.

18 – Biochemical changes produced in dTg animals were represented mostly by the high glycemic condition and luck of energy, explained by decreased insulin secretion. This condition implicitly led to weight loss of diabetic animals.

19 – Atypical morphology of pulmonary endothelium and high levels of HMGB1 protein detected in diabetic lung of dTg mice, which is explained by the high rate of synthesis and the translocation of HMGB1 from the nucleus to the cytosol, indicate the existence of the inflammatory process in the tissue.

20 –The inflammatory process revealed in diabetic lung is maintained and further enhanced by signaling pathways activated by HMGB1. Besides the high levels of RAGE in lung tissue of diabetic mice, the results demonstrated its activation by AKT phosphorylation and the high expression level of p65 subunit of NF-kB transcription factor. Because nuclear factor kB is involved in *de novo* synthesis of both RAGE and HMGB1, we consider that in diabetic lung was induced an inflammatory condition that can gain the amplitude necessary to produce changes in tissue histology and lung function impairment.

21 – In light of these data and their implications, possibly targeted therapies that block alarmin HMGB1 may be essential for reducing cardio-respiratory complications associated with hyperlipidemia and diabetes.

- 2012 -

INTRODUCERE

In ultimii ani, au fost detectate cateva proteine endogene capabile sa indice celulele si tesuturile lezionate. Aceste proteine pot initia raspunsuri inflamatorii si au fost clasificate din anul 2006, sub denumirea de alarmine (Bianchi M.E., 2007). Alarmina *high mobility group box 1* (HMGB1) a fost studiata si implicata in numeroase patologii, dar rolul ei nu a fost, inca, pe deplin inteles, ceea ce ne-a determinat ca in aceasta lucrare sa investigam modul in care proteina HMGB1 intervine in procesul inflamator prezent in hiperlipidemia si diabetul tip 1 indus experimental.

HMGB1 este o proteina nucleara cu o mobilitate crescuta si numeroase functii desfasurate la nivelul nucleului, dar care surprinzator detine un rol extracelular foarte important, reprezentat de capacitatea de a semnaliza distrugerea celulara si tisulara. Studiile realizate pana in acest moment au aratat ca proteina HMGB1 intervine in patogenia bolilor care prezinta, mai ales, stari inflamatorii acute si cronice. Totusi, exista numerose intrebari fara raspuns in acest moment, cu privire la modalitatile prin care alarmina HMGB1 induce si intretine inflamatia. Astfel, am considerat esentiala realizarea unor experimente care sa ne permita cunoastera si intelegerea modului in care proteina HMGB1 este implicata in mecanismele moleculare care intervin in declansarea si mentinerea proceselor inflamatorii asociate disfunctiilor vasculare din starea hiperlipidemica si diabetica.

Lucrarea de doctorat este structurata in doua parti, care cuprind in total 7 capitole, 68 figuri si 3 tabele. Prima parte, consacrata cunostintelor actuale in domeniul abordat, include 2 tabele si 20 figuri, dintre care 4 sunt originale, fiind realizate pe baza datelor din literatura, iar restul de 16 figuri sunt modificate sau preluate ca atare, mentionandu-se de fiecare data in text sursa si prelucrarile suferite. In partea a doua, atribuita contributiilor originale se gasesc un tabel si 48 figuri originale, insumand grafice, diagrame, electroforeze si montaje cu imagini de microscopie optica sau electonica. Teza contine 227 titluri bibliografice si are urmatorul cuprins:

In rezumatul de fata sunt prezentate pe scurt obiectivele, metodologia si concluziile generate pe baza rezultatelor obtinute in urma studiilor cuprinse in partea a II-a a lucrarii, **CONTRIBUTII ORIGINALE**.

Scop si obiective

Scop:

Studiile realizate in aceasta teza au urmarit rolul si modul in care proteina HMGB1 intervine in procesul inflamator instalat in conditii hiperlipidemice – aterosclerotice si de diabet tip I indus experimental.

Obiective:

a. Analiza distributiei celulare si subcelulare a proteinei HMGB1 in sistemul cardio-pulmonar supus procesului inflamator existent in conditii hiperlipidemice.

b. Contributia alarminei HMGB1 in semnalizarea celulara prezenta in inflamatia indusa de stresul hiperlipidemic.

c. Studierea proteinei HMGB1 in macrofagele activate prin expunere la serul hiperlipidemic.

d. Examinarea moleculului HMGB1 din punct de vedere genic si proteic dupa administrare tratamentului cu fluvastatina sodica la animalele cu placi aterosclerotice dezvoltate prin dieta hiperlipidemica.

e. Evaluarea efectului indus de admistrarea fluvastatinei sodice asupra proteinelor din cascada de semnalizare initiata de HMGB1 in timpul hiperlipidemiei induse experimental.

f. Investigarea localizarii proteinei HMGB1 in tesutul pulmonar supus stresului hiperglicemic din diabetul zaharat tip 1.

g. Detectia cailor de semnalizare activate de alarmina HMGB1 in palmanul diabetic.

Metodologie experimentala

1. Modele experimentale

   1.1 Hamsterul hiperlipidemic

   1.2 Soareci cu diabet tip 1 indus experimental

   1.3 Culturi celulare

2. Criosectiuni
3. Microscopie electronica
4. Determinari biochimice
5. Tehnica ELISA (Enzyme-linked immunosorbent assay)
6. Extractia de proteine
7. Electroforeza SDS-PAGE
8. Tehnica Western blot
9. Izolare ARN total
10. Real Time PCR semi-cantitativ
11. Analiza Statistica

Concluzii generale

Rezultatele studiilor efectuate in aceasta lucrare au aratat ca:

1 – Dieta hiperlipidemica poate induce eliberarea alarminei HMGB1 in ser, conferidu-i statutul de marker al evenimetelor aterosclerotice declansate ulterior de starea hiperlipidemica.

Pentru a demonstra daca dieta hiperlipidemica afecteaza cantitatea de HMGB1, s-a masurat, nivelul seric de HMGB1, folosind tehnica ELISA de captura. Valorile detectate pentru HMGB1 seric la hamsterii control (C) au fost in limite normale, de 4,2 ± 1,09 ng/ml. In schimb, hamsterii cu dieta hiperlipidemica (H) au avut concentratia serica de HMGB1 de 5 ori mai mare (21.2 ± 9.6 ng/ml; $p < 0.01$), comparativ cu grupul control (Fig. 30).

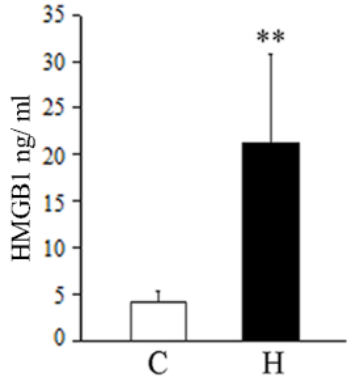

Fig. 1 Concentratia de HMGB1 detectata in serul animalelor hiperlipidemice prin metoda ELISA captura. Datele sunt prezentate ca medie ± SD; p** < 0,01 vs. C

2 – Expresia genica crescuta si nivelul proteic ridicat al alarminei HMGB1 in extractul proteic provenit din inima animalelor hiperlipidemice, indica existenta procesului inflamator la nivelul acestui organ.

La hamsterii hiperlipidemici s-a detectat ca expresia genei Hmgb1, izolat din ventriculul stang, creste de 1,89 ori fata de hamsterii control (Fig. 2*a*).

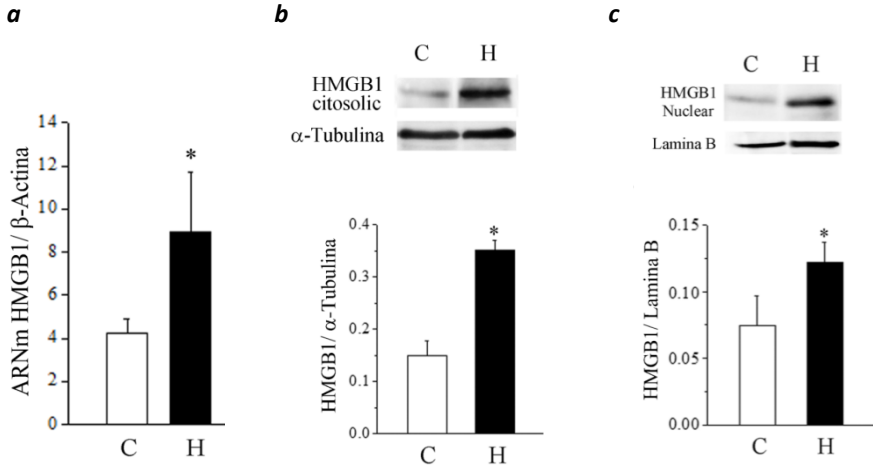

Fig. 2 HMGB1 in tesutul cardiac *(a)* Nivelul ARNm al HMGB1. *(b)* Identificarea prin *Western blot* a proteinei HMGB1 in fractia imbogatita in proteine citosolice *(c)*. Imuno-transfer reprezentativ pentru HMGB1 in fractia nucleara. Pentru normalizarea rezultatelor s-au folosit β-Actina, α Tubulina si respectiv Lamina B. Datele sunt prezentate ca medie ± SD; p* < 0,05 vs. C.

Datele obtinute prin *Western blot* au aratat ca la hamsterii hiperlipidemici nivelul de HMGB1 din fractia imbogatita in proteine citosolice, creste semnificativ ($p < 0,05$), acesta fiind de 2,35 ori mai mare comparativ cu animalele din grupul C (Fig. 2*b*), iar in fractiile imbogatite in proteine nucleare nivelul proteinei HMGB1 detectat a fost de 1.63 ori mai mare decat cel obtinut la hamsterii din grupul control (Fig. 2*c*).

3 – Plamanul animalelor hiperlipidemice a aratat o crestere a expresie genice si un nivel ridicat al proteinei HMGB1 in cele doua fractii proteice subcelulare analizate, semnalizand prezenta inflamatiei tisulare.

La animale hiperlipidemice, expresia genei Hmgb1 a inregistrat o crestere de 1,58 ori ($p < 0.05$) fata de animalele control. De asemenea, in fractia imbogatita in proteine citosolice a grupului H, nivelul proteinei HMGB1 este de 4.42 ori mai mare decat in cea a grupului C (Fig. 3*a*), iar in fractia nucleara a existat o

crestere semnificativa (p < 0,05) de 1,64 ori la hamsterii hiperlipidemici fata de grupul control (Fig. 3*b*).

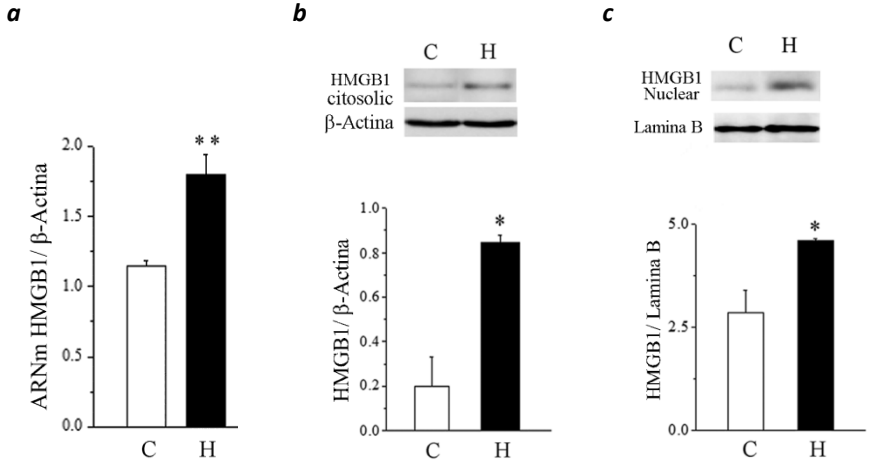

Fig. 3 Detectia proteinei HMGB1 in tesutul pulmonar. *(a)* Expresia genica a moleculei HMGB1 *(b)* Identificarea prin *Western blot* a proteinei HMGB1 in fractia imbogatita in proteine citosolice *(c)*. Imuno-transfer reprezentativ pentru HMGB1 in fractia nucleara. Pentru normalizarea rezultatelor s-au folosit β-Actina si respectiv lamina B. Datele sunt prezentate ca medie ± SD; p* < 0,05 vs. C, p** < 0,01 vs. C.

4 – Legatura demonstrata dintre HMGB1 si hiperlipidemia experimentala, ii ofera alarminei statutul de tinta certa a strategiei terapeutice folosita in vederea imbunatatirii starii clinice si pentru o evolutie favorabila a pacientului.

5 – In tesutul cardiac si pulmonar expresia proteica crescuta a proteinei HMGB1 se coreleaza pozitiv cu nivelul ridicat al receptorului RAGE si cu fosforilarea puternica a kinazei AKT. Aceste date ne ofera posibilitatea sa afirmam pentru prima data ca la animalele hiperlipidemice, interactiunea HMGB1 – RAGE poate mentine procesul inflamator prin activarea caii de semnalizare PI3K/ AKT.

Rezultatele obtinute au aratat ca in conditii hiperlipidemice nivelul receptorului RAGE creste semnificativ (p < 0.05), atat in inima cat si in tesutul

pulmonar, acesta fiind de 2,37 si respectiv 1,8 ori mai mare decat nivelul detectat la grupul C. In tesuturile analizate s-a putut observa la animalele H o fosforilare notabila a AKT1 la Thr^{308}, acesta fiind de 10 ori mai mare in tesutul cardiac si de 6 ori mai mare in cel pulmonar.

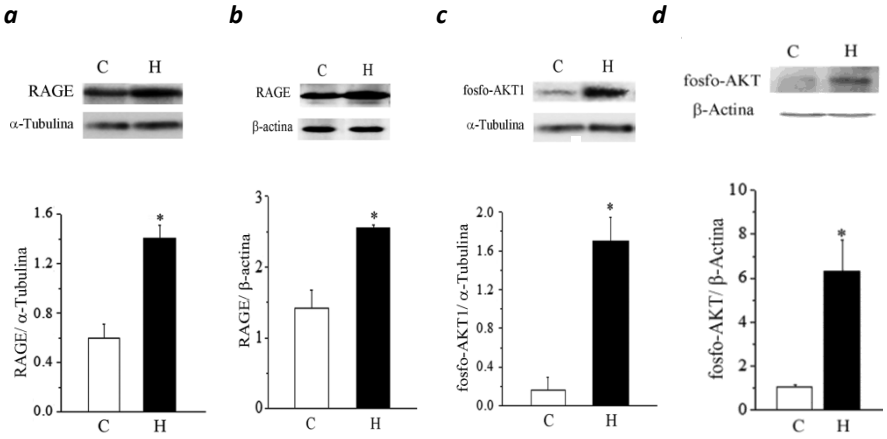

Fig. 4 Analiza receptorului RAGE Identificarea nivelului de AKT1 fosforilat. *(a)* Evidentierea receptorului RAGE in tesutul cardiac si *(b)* pulmonar. *(c)* Detectia AKT-1 fosforilat in inima si *(d)* palman. Pentru normalizarea rezultatelor s-au folosit α Tubulina si β-Actina. Datele sunt prezentate ca medie ± SD; p* < 0,05 vs. C.

7 – Administrarea fluvastatinei animalelor care au primit initial o dieta hiperlipidemica a avut un efect pozitiv la nivelul tesutului cardiac prin aducerea moleculului HMGB1 la un nivel genic si proteic asemanator cu cel detectat la animalele control.

La hamsterii hiperlipidemici tratati cu fluvastatina sodica (Ht) s-a detectat ca expresia genei Hmgb1, scade de 1,89 ori fata de hamsterii hiperlipidemici (Fig. 5*a*), iar nivelul proteinei HMGB1 in fractia citosolica este de 2,18 ori mai mic la animalele Ht comparativ cu cele din grupul H (Fig. 5*b*). Prin analiza densitometrica a benzilor proteice obtinute s-a demonstrat ca la hamsterii hiperlipidemici tratati, nivelul moleculei HMGB1 a scazut, in fractia nucleara, de 2,16 ori fata de grupul hamsterii hiperlipidemici (Fig. 5*c*).

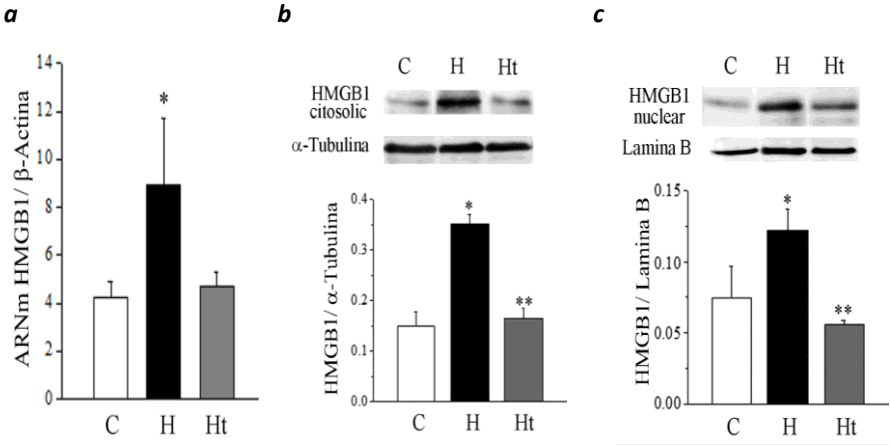

Fig. 5 Efectul produs de fluvastatina sodica asupra proteinei HMGB1 in inima. *(a)* Nivelul ARNm al HMGB1. *(b)* Imunodetectia alarminei HMGB1 in fractia imbogatita in proteine citosolice si *(c)* nucleare Pentru normalizarea rezultatelor s-au folosit β-Actina, α Tubulina si respectiv lamina B. Datele sunt prezentate ca medie ± SD; p* < 0,05 vs. C, p** < 001 vs H.

8 – Tratamentul cu fluvastatina a avut acelasi efect pozitiv asupra receptorului RAGE si a kinazei AKT1 fosforilate. Astfel, consecinta majora a acestor evenimente moleculare generate de actiunea fluvastatinei este reprezentata de diminuarea sintezei de novo a moleculelor pro-inflamatoare, inclusiv RAGE si HMGB1, avand consecinta reducerea inflamatiei tisulare.

Studiul in care s-a urmarit efectul hiperlipidemiei asupra caii de semnalizare initiata de HMGB1, a aratat ca la hamsterii hiperlipidemici expresia receptorului RAGE scadede 2,3 ori in grupul Ht in comparatie cu grupul H (Fig. 6*a*). De asemenea, rezultatele obtinute au indicat ca intre cele trei grupe de animale luate in studiu nu au existat modificari semnificative in nivelul de AKT1 in tesutul cardiac (Fig. 6*b*). Totusi, fluvastatina sodica a redus fosforilarea kinazei de 7,7 ori in grupul Ht fata de grupul H (Fig. 6*c*)

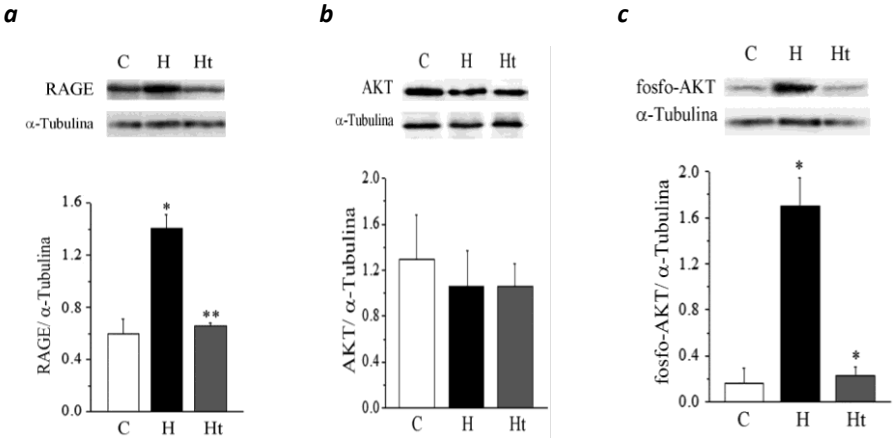

Fig. 6 Efectul pozitiv al tratamentului cu fluvastatina asupra moleculelor *(a)* RAGE, *(b)* AKT1 si *(c)* foso-AKT1 in tesutul cardiac. Datele sunt prezentate ca medie ± SD; p* < 0,05 vs. C, p** <0.01 vs. H.

9 – Un alt element de noutate demonstrat, il constituie capacitatea fluvastatinei de a reduce semnificativ concentratia serica a alarminei HMGB1.

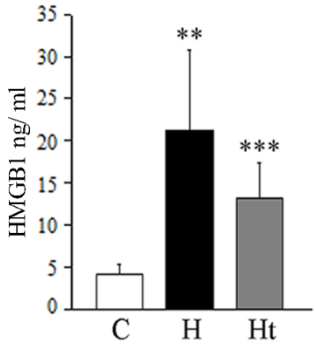

Fig. 7 Nivelul de HMGB1 seric detectat prin tehnica ELISA captura. Fiecare proba a fost masurata in triplicat. Datele sunt prezentate ca medie ± SD; p** < 0,01 vs. C, p*** <0.001 vs. C.

10 – La animalele tratate s-a inregistrat scaderea expresiei genice si proteice a HMGB1, in tesutul pulmonar. De asemenea, nivelul receptorului RAGE si gradul de fosforilare a kinazei AKT au fost in mod semnificativ reduse, fiind astfel afectata interactiunia HMGB1-RAGE si implicit semnalizare prin PI3K/ AKT, care activeaza factorul de transcriere NF-kB. Astfel, nivelul citokinelor pro-

inflamatorii va scadea, iar odata cu ele si procesul inflamator isi va pierde din intensitate.

Efectul medicamentului a fost observat si in plaman, unde expresia genica a proteinei HMGB1 a scazut de 1,46 ori la animalele tratate comparativ cu cea a grupului de animale hiperlipidemice, iar experimentele de imunnodetectie au confirmat scaderea expresiei proteice a HMGB1 de 1,2 ori in fractia citosolica (Fig. 45*a*) si de 1,27 (Fig. 45*b*) in fractia nucleara a hamsterilor tratati comparativ cu cei din grupul hiperlipidemic.

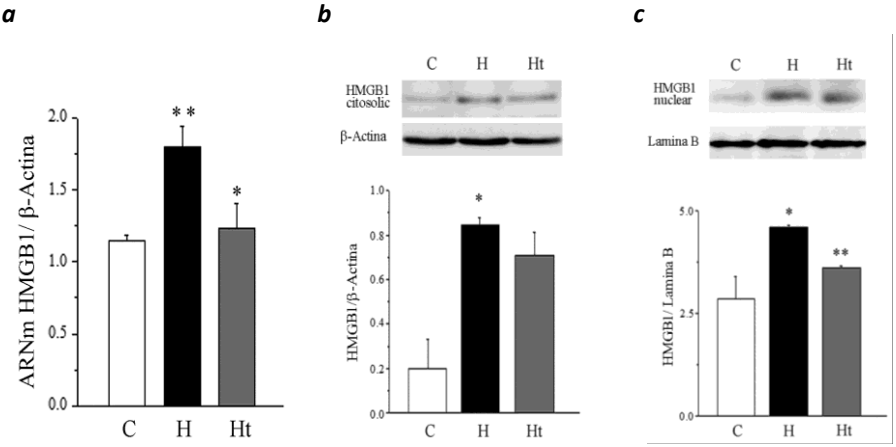

Fig. 8 Expresia genica *(a)* si proteica a moleculei HMGB1 in fractiile imbogatite in proteine citosolice *(b)* si nucleare *(c)* obtinute din tesutul pulmonar. Datele sunt prezentate ca medie ± SD; p** < 0,01 vs. C, p* <0.05 vs. H, corespunzatoare graficului (*a)*; p* < 0,05 vs. C, p** < 0,01 vs H, corespunzatoarea graficelor *(b)* si *(c)*.

Medicamentul administrat hamsterilor din grupul Ht a reusit sa scada de 2,6 ori efectul hiperlipidemiei asupra receptorului, asa cum se poate observa in Fig. 9*a*. In timp ce nivelul kinazei AKT1 a ramas aproape neschimbat la cele trei grupe de animale studiate (Fig. 9*b*), fosforilarea notabila a AKT1 la Thr^{308} observata in tesutul pulmonar al hamsterilor care au primit dieta hiperlipidemica a fost si de aceasta data redusa de 1,75 ori la hamsterii, carora li s-a administrat prin gavaj tratamentul cu fluvastatina sodica (Fig. 9*c*).

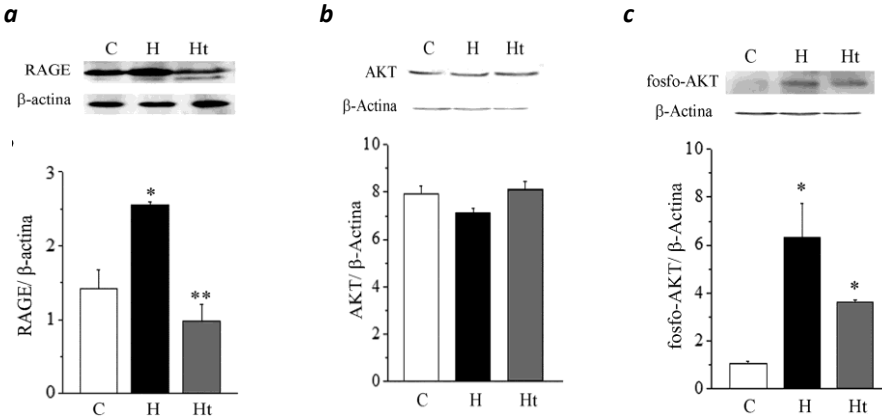

Fig. 9 Efectul pozitiv al tratamentului cu fluvastatina asupra moleculelor *(a)* RAGE, *(b)* AKT1 si *(c)* foso-AKT1 in plaman. Datele sunt prezentate ca medie ± SD; p* < 0,05 vs. C p** <0.01 vs. H, graficului (*a*); p* < 0,05 vs. C, corespunzatoarea graficelor *(b)* si *(c)*.

11 – Experimentele prezentate aduc noi dovezi care sustin ipoteza ca alarmina HMGB1 functioneaza ca un mediator al inflamatiei sistemice generate in timpul stresului hiperlipidemic.

12 – Modelul experimental *in vitro* propus, se incadreaze in categoria modelelor folosite in studierea celulelor spumoase, populatie preponderenta in leziunile aterosclerotice.

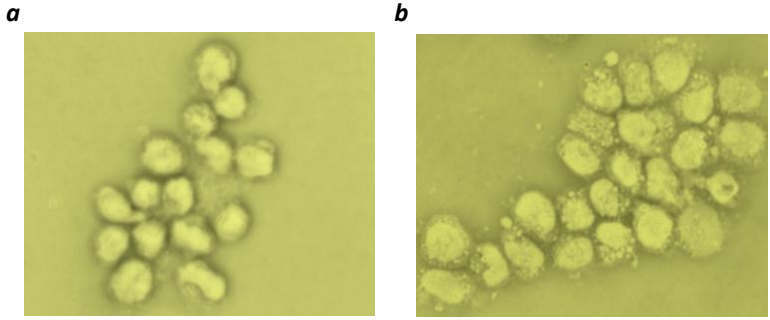

Fig. 10 Aspectul macrofagelor in cultura dupa 48h. *(a)* Celule control; *(b)* Celule activate cu ser hiperlipidemic. Imagini realizate in contrast de faza cu obiectivul 40x.

13 – Serul hiperlipidemic induce translocarea alarminei HMGB1 din nucleu in citoplasma, proces demonstrat prin cantitatea semnificativ redusa de HMGB1 in nucleu, dar crescuta in citosolul macrofagelor, pentru ca in final HMGB1 sa fie secretata in mediul extracelular.

Analiza densitometirca a benzilor proteice detectate cu anticorpi specifici a aratat ca in cazul celulelor activate (A), nivelul citosolic al moleculei HMGB1 a fost de 1,5 ori mai mare decat la celulele control (C), dar nivelul nuclear al proteinei a fost de 7 ori mai mic la celulele A comparativ cu celulele C, demonstrandu-se astfel ca serul hiperlipidemic folosit in activarea monocitelor U937 este capabil sa produca relocalizarea proteinei HMGB1 din nucleu in citosulul macrofagelor incarcate cu lipide.

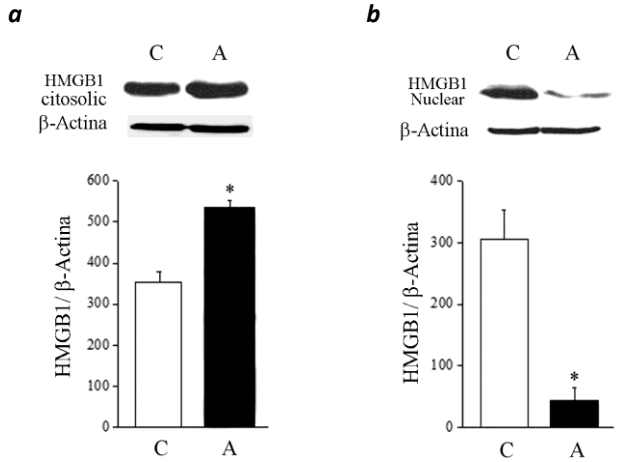

Fig. 11 Localizarea proteinei HMGB1 in fractia imbogatita in proteine citosolice *(a)* si nucleare *(b)* izolate din celulele control si activate cu ser hiperlipidemic. Datele sunt prezentate ca medie ± SD; p* < 0,05 vs. C.

14 – Rezultatele obtinute fac posibila introducerea proteinei HMGB1 pe lista citokinelor implicate in patogenia aterosclerozei, avand in vedere relocalizarea sa subcelulara in macrofagele incarcate cu lipide, ceea ce indica existenta unui rol important al alarminei HMGB1 inca din etapele timpurii ale procesului aterosclerotic.

15 – Macrofagele activate cu ser hiperlipidemic exprima pe suprafata lor receptorul RAGE intr-o cantitate mai mare decat celulele control. In acelasi context hiperlipidemic, a fost evidentiata activarea caii de semnalizare PI3K/AKT la macrofagele activate, prin fosforilarea kinazei AKT la treonina din pozitia 308.

Analiza densitometrica a benzilor proteice obtinute a aratat ca serul hiperlipidemic actioneaza asupra exprimarii proteinelor implicate in cascada de semnalizare HMGB1-RAGE via AKT.

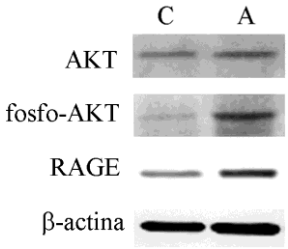

Fig. 12 Evidentierea prin *Western blot* a proteinelor AKT1, fosfo-AKT1, RAGE si β-actina in celule U 937 control si activate cu ser hiperlipidemic.

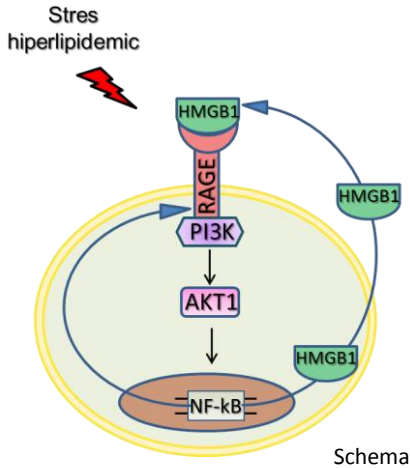
16 – Rezultatele studiului *in vitro* reprezinta o dovada clara ca HMGB1 este un mediator important al inflamatiei declansate de stresul hiperlipidemic, iar blocare ei ar putea reprezenta o cale fezabila de a incetini procesul aterogenic.



Schema personala

Fig. 13 HMGB1 mediator al procesului inflamator initiat de stresul hiperlipidemic

In urma corelarii acestor date cu cele obtinute anterior, consideram ca alarmina HMGB1 este secretata de macrofagele incarcate cu lipide, iar dispunerea ei in mediul extracelular ii va permite interactiunea cu receptorul RAGE, exprimat pe suprafata acestor celule. Astfel, HMGB1 intretine procesul inflamator declansat de stresul hiperlipidemic.

17 – Animalele dublu transgenice (dTg) au suferit pe parcursul a opt saptamani diferite dezechilibre metabolice si somatice care au condus la instalarea diabetului zaharat de tip 1, reprezentand o alegere conforma cu cerintele experimentelor.

18 – Modificarile biochimice produse la animale dTg, reprezentate mai ales de nivelul glicemic ridicat, a generat acestor animalele o stare lipisita de energie, explicata prin lipsa insulinei care asigura necesarul energetic celular. Aceasta stare a dus implicit la scaderea in greutate a animalelor diabetice.

Tabel 1

Caracteristicile animalelor control si diabetice

Grupa de animale	sTg	dTg
Greutate corp (g)	25 ± 0.5	16 ± 0.5
Glucoza (mg/dl)	110± 1.5	430 ± 2.5

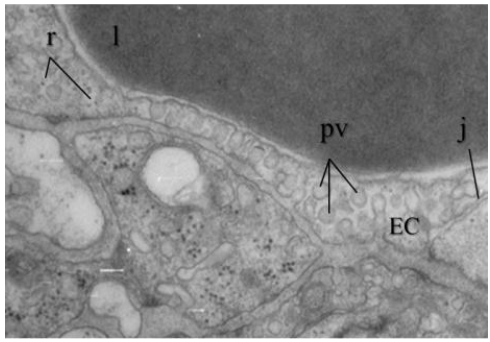
Datele sunt prezentate ca medie ± SEM.

19 – Morfologia atipica a endoteliului vascular pulmonar detectata la soarecii dTg si nivelul ridicat al proteinei HMGB1 in plamanul diabetic, fapt explicat prin rata mare de sinteza a HMGB1 si prin translocarea ei din nucleu in citosol, indica existenta procesului inflamator la nivelul acestui tesut.

La soarecii dTg, microscopia electronica a permis detectia unor modificari structurale evidente la nivelul celulelor endoteliale din capilarele pulmonare. Astfel, endoteliul a afisat un aparat sintetic bine dezvoltat reprezentat de reticulum endoplasmatic si numerosi ribozomi indicand o intensa activitate secretorie. In plus, la soarecii dublu transgenici, numarul caveolelor endoteliale a fost mai ridicat decat la soarecii din grupul control. De asemenea, lamina bazala a

fost considerabil ingrosata la soarecii dTg, comparativ cu cea a soarecilor sTg (Fig. 14).

a



b

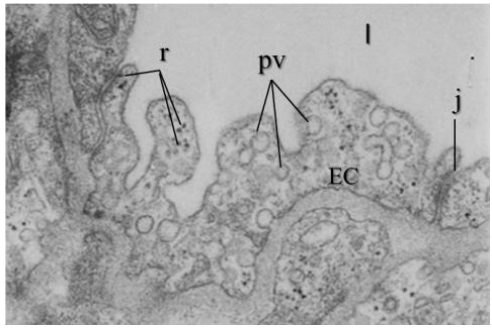


Fig. 14 Microscopia electronica a endoteliului vascular pulmonar la animalele sTg folosite control *(a)* si dTg *(b)* ; r: ribozomi, l:lumen, pv: vezicule plasmalemale, j: jonctiune. Bara = 200 nm

Evaluarea proteinei HMGB1 in tesutul pulmonar al soarecilor sTg si dTg, s-a realizat atat prin tehnica de real time PCR cat si Western blot, pentru a putea stabili si evidentia cu certitudine existenta eventualelor modificari din expresia genica, respectiv proteica a moleculei. Astfel, la soarecii diabetici s-a detectat ca expresia genei Hmgb1, creste de 1,75 ori fata de soarecii control (Fig . 15*a*), nivelul alarminei HMGB1 in fractia imbogatita in proteine citosolice creste semnificativ,

acesta fiind de 3,14 ori mai mare comparativ cu animalele din grupul C (Fig. 15*b*), iar in
fractia imbogatita in proteine nucleare creste de 3,94 ori comparativ cu animalele din grupul control (Fig. 15*c*).

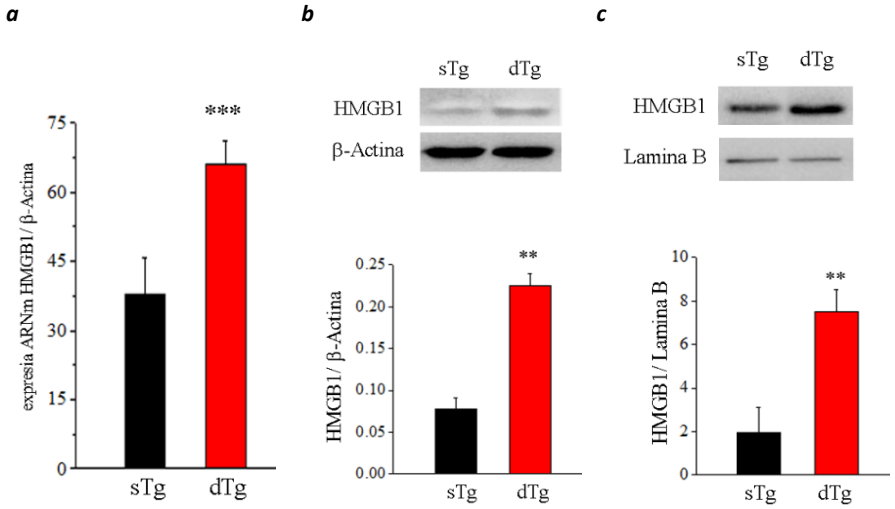

Fig. 15 Expresia genica *(a)* si proteica a moleculei HMGB1 in fractiile imbogatite in proteine citosolice *(b)* si nucleare *(c)* obtinute din tesutul pulmonar al soarecilor sTg si dTg. Datele sunt prezentate ca medie ± SD; p** < 0,01 vs. sTg, p*** < 0,001 vs. sTg.

20 – Procesul inflamator pus in evidenta in plamanul diabetic, este mentinut si ulterior amplificat prin caile de semnalizare activate de alarmina HMGB1. Astfel, nu a fost semnalt doar nivelul ridicat al receptorului RAGE in tesutul pulmonar al soarecilor diabetici, ci si activarea lui, evidentiata prin fosforilarea kinazei AKT1 si prin nivelul ridicat al subunitatii p65 a factorului de transcriere NF-kB. Deoarece, factorul nuclear kB este implicat in sinteza de novo atat a receptorului RAGE cat si a alrminei HMGB1, consideram ca in plamanul diabetic este indusa o stare inflamatorie care poate capata amploarea necesara pentru producerea modificarilor histologice tisulare si a afectarii functiei pulmoare.

Experimentele au demonstrat ca in plamanul diabetic nivelul receptorului creste semnificativ, acesta fiind de 3,58 ori mai mare comparativ cu nivelul detectat la soarecii control (Fig. 16*a*). Nivelul de fosfo-AKT din tesutul pulmonar a crescut de 2,56 ori la grupul dTg

comparativ cu grupul sTg (Fig. 16*b*), iar expresia proteica a NF-kB p65 creste semnificativ la soarecii dTg, avand un nivelul de 7,2 ori mai mare decat la soarecii sTg.

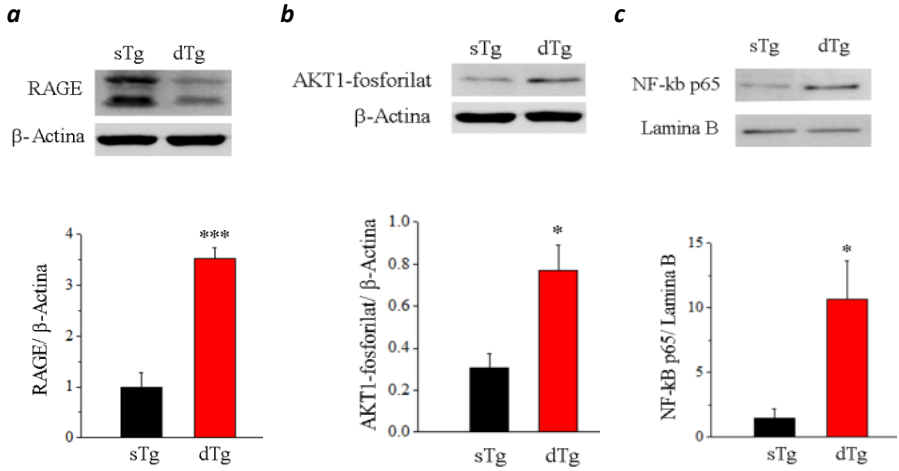

Fig. 16 Imunodetectia receptorului RAGE *(a)*, foso-AKT1 *(b)* si a factorului de transcriere NF-kB subunitatea p65 *(c)* in tesutul pulmonar. Datele sunt prezentate ca medie ± SD; p* < 0,05 vs. sTg, p*** < 0,001 vs. sTg.

In concluzie, rezultatele obtinute au demonstrat ca procesul inflamator pus in evidenta in plamanul diabetic, este mentinut si ulterior amplificat prin caile de semnalizare activate de alarmina HMGB1.

21 – In lumina acestor date si a implicatiilor lor, eventule terapii tintite care sa urmareasca blocarea alarminei HMGB1 ar putea fi esentiale pentru diminuarea complicatiilor cardio-respiratorii asociate hiperlipidemiei si diabetului.

PN-III-P1-1.1-TE-2019-2044 (acronim A2A)
„Peptide derivate din apolipoproteina A-II cu potential terapeutic in ateroscleroza”

RAPORT ȘTIINȚIFIC
privind implementarea proiectului in perioada 01/01/2021 - 31/12/2021

In cadrul proiectului de cercetare **PN-III-P1-1.1-TE-2019-2044 (acronim A2A)** cu titlul: „Peptide derivate din apolipoproteina A-II cu potential terapeutic in ateroscleroza” au fost realizate următoarele activități planificate in cadrul Etapei 2:

Etapa 2 - Generarea de adenovirusuri recombinante care codifică peptide derivate apoA-II cu cisteină (SSCH1, SSCH2, SSCH3, SSCH1H2, SSCH2H3), precum și apoA-II cu lungime completă.

Activitatea 2.1 - Generarea de adenovirusuri recombinante care codifică peptide derivate apoA-II cu cisteină precum și apoA-II cu lungime completă,

Activitatea 2.2 - Amplificarea adenovirusurilor recombinante care codifică peptide derivate apoA-II cu cisteină precum și apoA-II cu lungime completă,

Activitatea 2.3 - Purificarea adenovirusurilor care codifică peptidele derivate din apoA-II,

Activitatea 2.4 - Titrarea adenovirusurilor care codifică peptidele derivate din apoA-II.

Activitatea 2.1 - Generarea de adenovirusuri recombinante care codifică peptide derivate apoA-II cu cisteină precum și apoA-II cu lungime completă:

In cadrul acestei activitati au fost obținute adenovirusuri care codifica peptide derivate din apoA-II (SSCH1, SSCH2, SSCH3, SSCH1H2, SSCH2H3), precum și apoA-II cu lungime completă. După confirmarea prin digestie enzimatică, din fiecare clona pozitiva selectata s-a realizat amplificarea ADN in bacterii DH5α si s-a obtinut o cantitate mare de ADN (folosind kitul Midiprep de la Qiagen).

Activitatea 2.2 - Amplificarea adenovirusurilor recombinante care codifică peptide derivate din apoA-II cu cisteină precum și apoA-II cu lungime completă:

Celulele AD293 au fost insamantate in flaskuri T25 si transfectate cu ADN recombinant linearizat cu enzima de restricție *PacI*. Dupa 12 zile, mediul cu celule transduse a fost colectat si centrifugat. Sedimentul celular a fost resuspendat in PBS si supus unor cicluri de inghetare (in azot lichid) - dezghetare (la 37°C) succesiv de trei ori, apoi a fost trecut prin seringa (23G). Atat mediile colectate cat si sedimentele obtinute au fost adaugate peste celule AD293 (insamantate cu o zi inainte). Adenovirusurile au fost amplificate succesiv in flask-uri T75 → T175 → 5 flaskuri T175 → ≥ 25 flaskuri T175. Intrucat vectorul adenoviral utilizat in obtinerea adenovirusurilor (care codifica pentru proteina ApoA-II) produce si proteina fluorescenta verde (GFP, Green Fluorescence Protein), celulele care au produs adenovirusul au putut fi monitorizate si prin microscopie de fluorescenta.

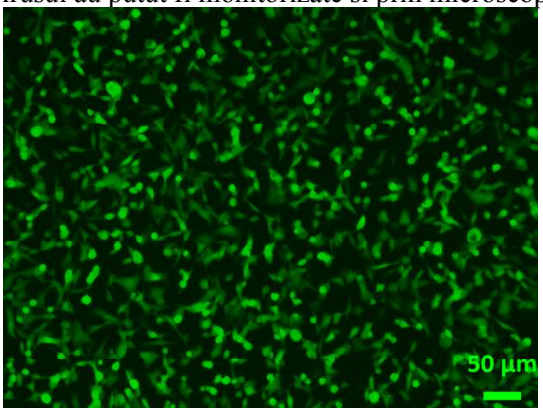

Fig 1. Imaginea celulelor AD293 transduse cu adenovirus ApoA-II (la microscopul de fluorescenta).

Activitatea 2.3 - Purificarea adenovirusurilor care codifică peptidele derivate din apoA-II:

Mediul continand celule transfectate cu adenovirus au fost colectate si centrifugate. Adenovirusurile din mediu au fost precipitate utilizand sulfat de amoniu, apoi a fost realizata purificarea adenovirusurilor prin ultracentrifugare in gradient de CsCl urmata de dializa. In paralel cu mediul, celulele care au produs adenovirusurile au fost colectate, centrifugare si supuse unor cicluri consecutive inghet/dezghet, apoi s-a efectuat purificarea adenovirusurilor prin ultracentrifugare in gradient de CsCl.

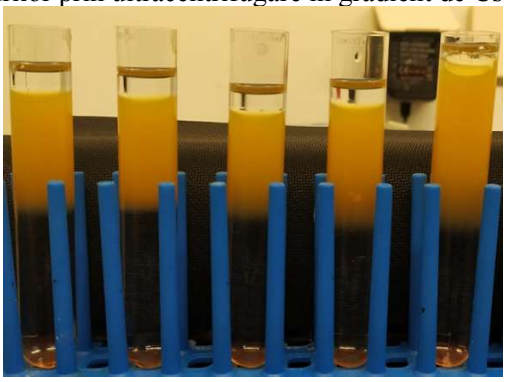

Fig 2. Incarcarea cu probe a coloanelor de ultracentrifuga in vederea purificarii adenovirusului ApoA-II prin ultracentrifugare in gradient de CsCl.

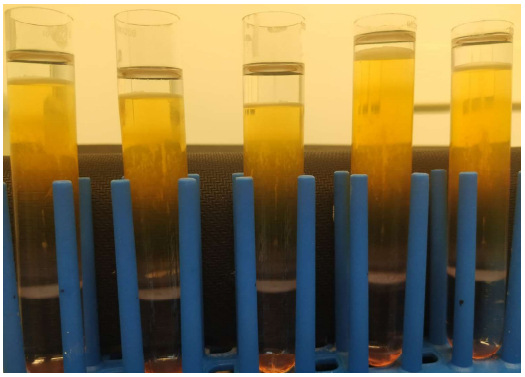

Fig 3. Purificarea adenovirusului ApoA-II prin ultracentrifugare in gradient de CsCl.

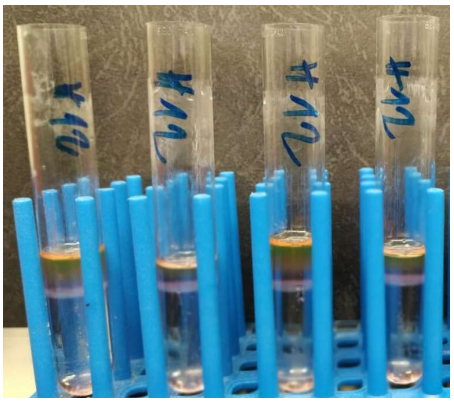

Fig 7. Purificarea fragmentului ApoA-II H1H2 prin ultracentrifugare in gradient de CsCl.

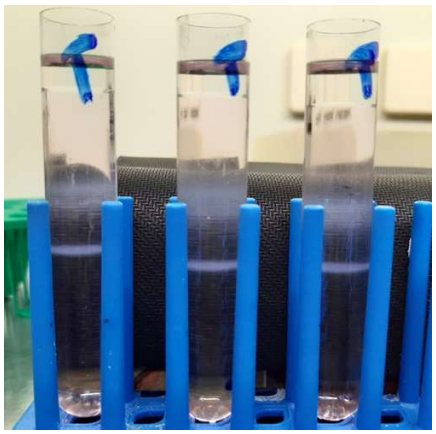

Fig 8. Purificarea ApoA-II total prin ultracentrifugare in gradient de CsCl.

Activitatea 2.4 - Titrarea adenovirusurilor care codifică peptidele derivate apoA-II:

Titrarea adenovirusurilor care codifică peptidele derivate din apoA-II a fost realizata prin citometrie in flux, in urma transducerii celulelor AD293 cu adenovirus purificat. Au fost realizate dilutii seriale ale stocului viral (10^{-3}-10^{-7}) si au fost evaluate celulele GFP pozitive prin citometrie in flux.

Titrul adenoviral obtinut a fost cuprins intre 1.7- 4.3x10^{11} TU/ml (TU=Transforming Units).

Titrul viral a fost calculat utilizand urmatoarea formula:

TU/ml=D*F/100*C/V

D=factor de dilutie
F=numarul de celule pozitive/100
C=numarul de celule/godeu
V=volumul de inocul

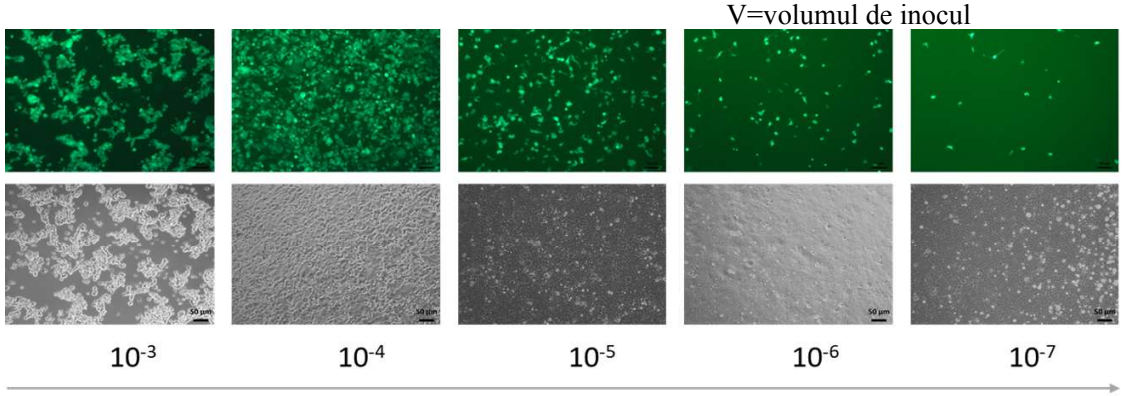

Fig 9. Titrarea adenovirusului apoA-II: celulele AD293 au fost transduse cu adenovirus folosind diferite dilutii seriale ale stocului viral (10^{-3}-10^{-7}).

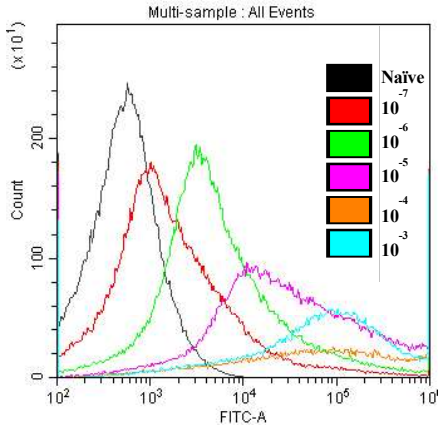

Fig 10. Titrarea adenovirusului apoA-II: celulele au fost transduse cu adenovirus folosind diferite dilutii seriale ale stocului (10^{-3}-10^{-7}), iar dupa 48 de ore de la transducere celulele GFP pozitive au fost evaluate prin citometrie in flux.

Titrul viral al adenovirusurilor care codifică peptide derivate apoA-II cu cisteină (SSCH1, SSCH2, SSCH3, SSCH1H2), precum și apoA-II cu lungime completă a fost cuprins intre **1.7-4,3x10^{11} TU/ml**.

Diseminarea rezultatelor: Rezultatele obținute in cadrul proiectului au fost prezentate sub forma de postere si prezentari orale la următoarele manifestări științifice:

- "**Generation of recombinant adenoviruses encoding ApoA-II**", Gabriela Florea, Irina F. Tudorache, Violeta G. Trusca, Anca V. Gafencu, poster prezentat la „A 23 a Conferinta Internationala: Materials, Methods & Technologies", organizata in Burgas, Bulgaria in perioada 19-22 August 2021.
- "**An optimised method to obtain recombinant adenoviruses**", prezentare orala sustinuta de catre Violeta Trusca la „A 23 a Conferinta Internationala: Materials, Methods & Technologies", organizata in Burgas, Bulgaria in perioada 19-22 August 2021.
- **„Generation of recombinant adenoviruses encoding ApoA-II**", autori Gabriela Florea, Irina F. Tudorache, Violeta G. Trusca, Laura Moise, Madalina Fenyo, Anca V. Gafencu, poster prezentat la simpozionul aniversar „International Conference under the aegis of the Romanian Academy - The 42nd Anniversary Symposium of The Institute of Cellular Biology And Pathology "Nicolae Simionescu" held jointly with The 38th Annual Scientific Session of The Romanian Society For Cell Biology - "From basic cell biology to personalized medicine during Covid-19 pandemic; creativity and vision in a rapidly changing world", 4-6 Noiembrie, 2021.
- **„Understanding apolipoprotein gene regulation, a key step toward the development of successful therapies for reduction of atherosclerosis",** prezentare orala sustinuta de catre Violeta Trusca la simpozionul aniversar „International Conference under the aegis of the Romanian Academy - The 42nd Anniversary Symposium of The Institute of Cellular Biology And Pathology "Nicolae Simionescu" held jointly with The 38th Annual Scientific Session of The Romanian Society For Cell Biology - "From basic cell biology to personalized medicine during Covid-19 pandemic; creativity and vision in a rapidly changing world", 4-6 Noiembrie, 2021.

Publicații: „***Apolipoprotein A-II - role in health, cardiovascular disease, diabetes, cancer, and other pathologies***", autori Gabriela Florea, Irina Florina Tudorache, Madalina Dumitrescu, Ioana Madalina Fenyo, Violeta Georgeta Bivol (Trusca), Anca Violeta Gafencu, manuscris in preparare. „***The Promise of Apolipoprotein AI-Based Therapy***", Trusca VG, Austin Journal of Molecular and Cellular Biology.

In concluzie, obiectivul etapei 2 al proiectului PN-III-P1-1.1-TE-2019-2044 (A2A): „Generarea de adenovirusuri recombinante care codifică peptide derivate din apoA-II, precum și apoA-II cu lungime completă" a fost îndeplinit in totalitate.

PROGRESS REPORT – 2nd year

Runtime of the project:
x☐ 2nd year

Period covered:
From 12 /06/2018 to 12/05/2019

Acronym	XploreCAD
Project Title	Advanced ex vivo analyses and multi-frequency ultrasound technology for improved evaluation and diagnosis of coronary plaque
Start Date Consortium	December 19th, 2017
Date of the Report	March 2019

PARTNERS

Number	Principal Investigator	Organisation	Country
1 (Coordinator)	Rune HANSEN	Stiftelsen SINTEF, Trondheim	Noeway
2	Felicia ANTOHE	Institute of Cellular Biology and Pathology N. Simionescu, Bucharest	Romania
3	Mathieu LEGROS	Vermon, SA, Tours	France
4 (Associated partner)	Kenneth Caidahl	Karolinska University Hospital	Sweden

1. Achievement of planned objectives

Describe the activities that have been performed during the year to meet the objectives given in the proposal. Outline the work carried out by each partner. Explain the progress of the work in line with the work plan (including milestones and deliverables). Estimate the current degree of completion of the objectives (Max. 2 pages).

The activities performed in this period were fully complete according to the Gantt diagram. The M1.1a was completed and the M1.2a was started with bioinformatics analysis and validation of the results generated by mass spectrometry analysis. Simultaneously selection and significance of the data will be performed to finish the proposed milestones and to build the reports for M1.2a; M1.1b; M2.1 in due time (end of 2020).

***In vivo* experimental design and preliminary results**

As mentioned in the first year report the experimental lot of 40 rabbits described in the project was split in two because of the limited logistical capacity of the subcontracted animal facility located at National Institute of Research and Development Cantacuzino (INCDMM), Contract No. A420, 23/04/2018. Thus the first lot of 20 rabbits (Stage I) was developed and completed between: August and November 2018. The next lot (Stage II) was developed between March and June 2019. At this time all the animals were processed and tissue samples and blood were harvested and deposited at low temperature to be analysed. The partial preliminary results of the Stage I (M1.1a) were reported on December 5th, 2018 to the UEFISCDI, the financial authority and could be found at the following web

site address: http://www.icbp.ro/static/en/en-networking_grants-grants-international/xplorecad.html.

The WP2 of the full proposal was focused on the evaluation of selected alarmins in plaques and sera of atherosclerotic patients. Up until this moment, patient enrollment and sample collection have been performed, as initially proposed, by KUH partner.

Related to the alternatives described in the WP2 tasks about the proteomic evaluation of plaques/serum from atherosclerotic patients, we all decided according to the suggestion of Ulf Hedin to skip the part related to proteomics on human plaques because this to a large extent already was done within their BIKE project.

Since part of the activities, concerning the mass spectrometric analyses have already been performed by KUH partner during another study, the ICBP partner remains with the on-going tasks of confronting and corroborating the results coming from the aortic, carotid and coronary plaque mass spectrometric analyses from the atherosclerotic rabbit model with the results obtained by the KUH partner from human carotid plaques. Qualitative and semi-quantitative data from the two types of samples will be compared using Protein Center LIMS bioinformatics platform for proper data management and relevant projection of alarmin biomarker pattern potential in order to propose selected molecules for microbubble targeting purposes and detection using the proposed ultrasound transducer.

By analyzing blood and plaque samples from both patients and animal models, the XploreCAD project will identify potential biomarkers of coronary artery disease. Using a new atherosclerotic animal model, the New Zeeland White Rabbits exposed to hyperlipidemia in the presence or absence of statins in association with PCSK9 inhibitors, we can safely assume that the high-performance technologies proposed will evidence modified profiles of pro- inflammatory cytokines, adhesion factors and regulatory proteins that can reduce atheroma plaques for the benefit of human health. In Figure 1 the general protocol followed to implement the project is shown as an interconnected diagram.

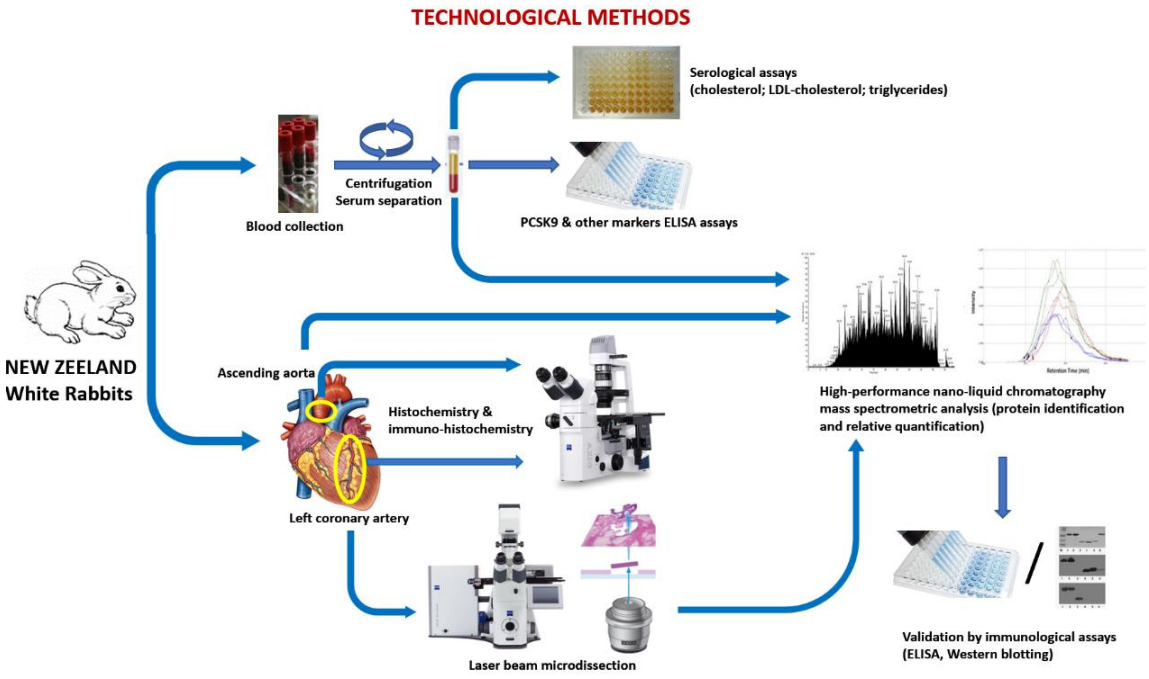

***Figure 1**. The novel design of the experimental model for atherosclerosis and the smart selection of clinical, biochemical and mass spectrometry tecnologies were carrefuly selected to unreveal the potenial biomarkers responsible for the residual risks in cardiovascular disease under agresive treatment with low lipid drugs.*

Progress / Intermediary results

After 12 weeks the tissue fragments harvested from all animal groups demonstrated that atherosclerotic advanced unstable plaques were developed in the lesion pron-areas of all animals fed high fat diet and the applied treatment reduced significantly the plaques dimension and also the histologycal aspects of the lesion.
Significant macroscopic modification could be observed when the animals were euthanized and the aorta, heart, carotid arteries tissue fragments were harvested from each animal. In Fig. 2, upper pannel, the general aspect of the liver can be visualised and is indicative of the effects of the hyperlipidemic diet. The lower pannel of Fig. 2 demonstrated severe lipid deposits in a representative Oil Red O coronary artery stained section, as opposed to the C and As animals.

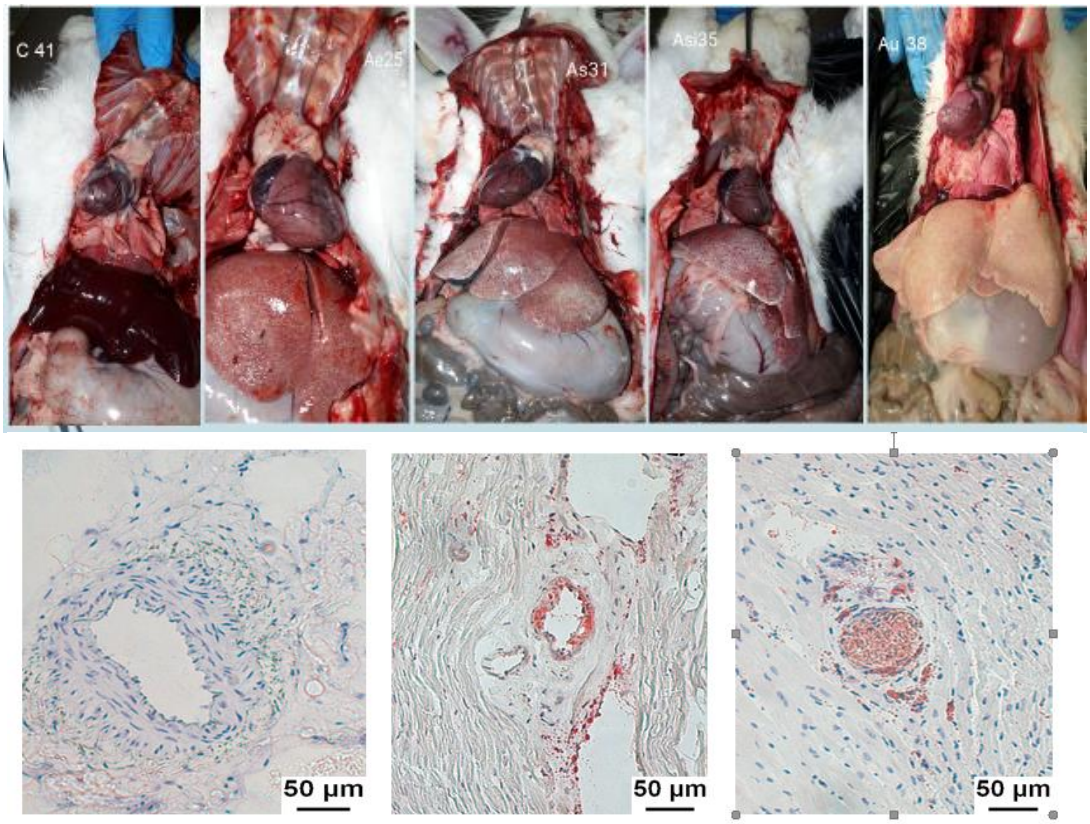

Figure 2 *.The macroscopic aspects of the internal organs of C, Ae, As, Asi and Au rabits (from left to right) at the end of the experiment (after 12 weeks) are presented in the upper pannel. Representative hematoxilin and lipid specific Oil Red O dye stainings of coronary artery frozen sections of C, As and Au (from left to right) animals are depicted in the lower pannel.*

One of the highlights of the XploreCAD project was the analysis of molecules or molecular patterns such as alarmins, to discriminate the different stages of atheroma plaque progression and better explain the residual risk of cardiovascular-related events and mortality after treatment with conventional and/or modern specific drugs. These molecules are a class of multifunctional endogenous proteins released under long-lasting stress factors, such as the hyperlipidemic diet.
In this regard, the ICBP partner has been responsible for the *in vivo* experimental design in order to assess and reveal specific patterns of alarmins and other molecules in early/ vulnerable plaques of hyperlipidemic animals when compared to appropriate controls. The proposed mass spectrometry-based proteomic analysis tackles both the local, tissue level of alarmins (and other significantly altered resident molecules) but also their circulating levels inside the blood flow.
The hyperlipidemic, as well as the animal groups which received treatments were evaluated at different time points for plasma lipid and glucose levels using specific assay kits from DIALAB GMBH (Wiener Neudorf, Austria) (Fig. 3).

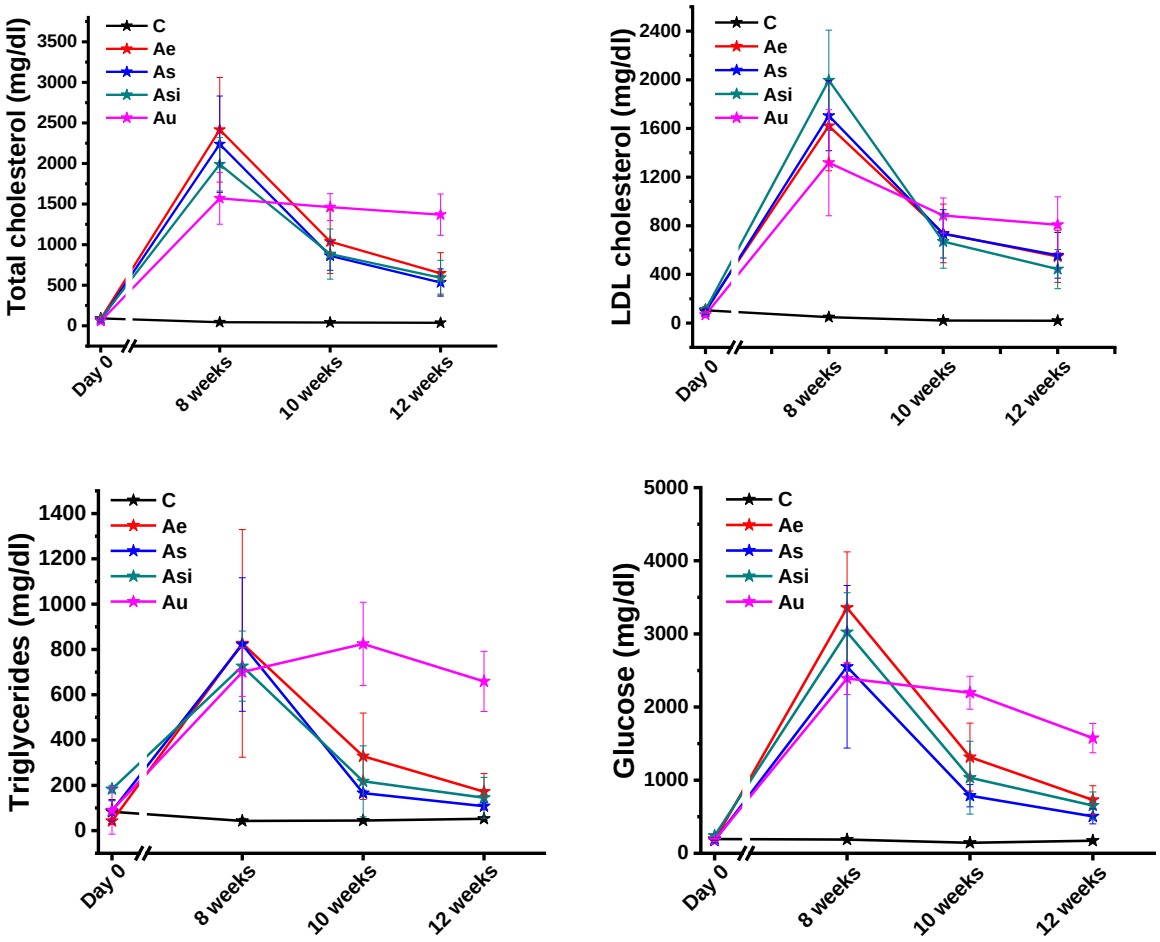

Figure 3: *Plasma quantitation of total cholesterol, LDL cholesterol, triglycerides and glucose levels for the 5 animal groups proposed in this study during the 12 weeks of animal experimentation: C- control group, Ae – early atherosclerotic group, As – statin and PCSK9 antibody stabilized atherosclerotic group, Asi – statin and PCSK9 siRNA stabilized atherosclerotic group and Au – vulnerable atherosclerotic group.*

Representative frozen sections of coronary arteries were laser- microdissected using the Zeiss PALM microbeam laser microdissection system (Oberkochen, Germany), to specifically isolate the coronary atheroma plaques (Fig. 4). The samples were suitably prepared for nano liquid chromatography – tandem mass spectrometric analysis using the Easy nLC II system coupled to the LTQ Orbitrap Velos Pro ETD hybrid mass spectrometer (Thermo Scientific, Illinois, USA), as previously mentioned (1). In parallel, tissue homogenates from carotid and ascending thoracic artery areas were performed to further corroborate the alarmin and other significantly altered protein levels along the lesion-prone area of the vascular tree. Sera samples harvested at the end of animal experimentation period were used for exosome isolation (using the miRCURY Exosome Serum/Plasma Kit from Qiagen, Venlo, The Netherlands) and proteomic analysis.

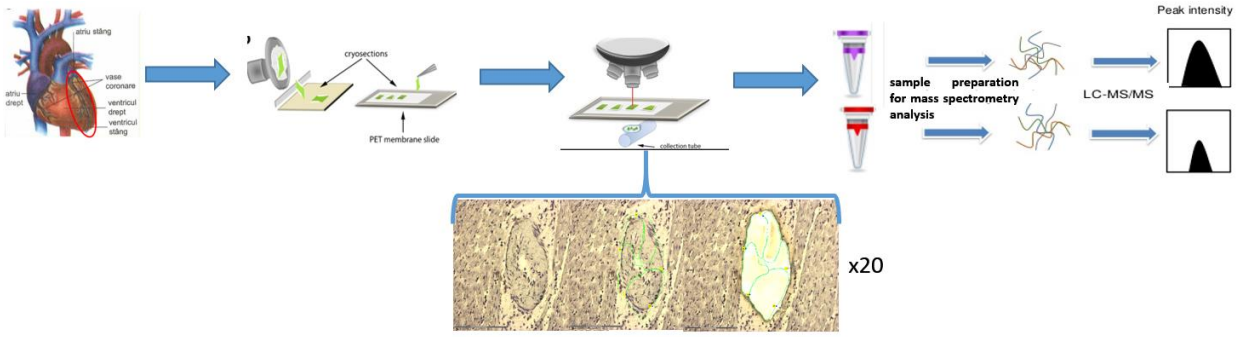

***Figure 4**: Coronary atheroma plaque laser microdissection workflow. Frozen coronary arteries, embedded in NEG-50 optimal cutting temperature medium were sectioned and stained with hematoxylin dye. The atherosclerotic lesions were laser-microdissected and the harvested material (~5mm^2) from each animal was solubilized and prepared for mass spectrometric analysis.*

The shotgun proteomic analysis (Proteome Discoverer 2.4, Thermo Scientific) revealed a plethora of alarmins and other molecules that were generally identified with high confidence in all animal groups proposed in this study.
The proteomic analysis of the microdissected atheroma plaque samples evidenced a total of 615 proteins, 77 of which were uniquely observed in the Ae group, 61 in the As group, 130 in the Asi group and 131 were only identified in the Au group. 41 proteins were common to all groups taken in this study (Fig. 5).

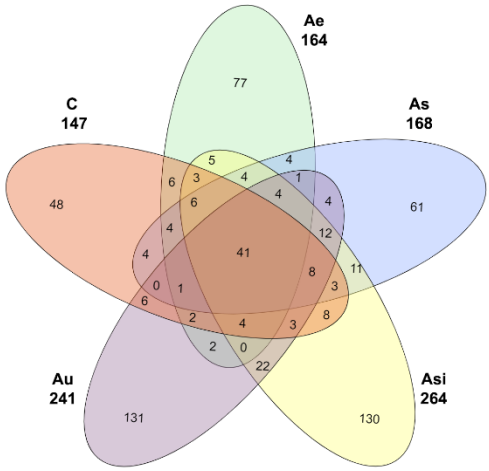

***Figure 5:** Venn intersection of the identified proteins from the laser microdissected atheroma plaques of the C, Ae, As, Asi, and Au animal groups.*

The alarmins identified in the experimental animal groups in all conditions and different areas of vascular bed are presented in Table 1. The recently performed protein inference will be closely followed by label-free relative mass spectrometric quantification and immunological validation. These studies will reveal which alarmins as well as the associated molecules will be differentially regulated by the hyperlipidemic diet and/or the anti-atherosclerotic treatment.

***Table 1**: Alarmins identified in the thoracic aorta, carotid, coronary artery samples and serum exozomes from all types of experimental animal groups (C, Ae, As, Asi, and Au) using mass spectrometric analysis. The experiment was performed in three technical replicates using three biological animals per group.*

The Sequest score is presented and reveals the confidence level of the identified proteins. A Sequest Score > 10 is generally accepted as the minimum confidence threshold of an inferred protein molecule.

No.	UniProt code	Protein description	Thoracic aorta	Carotid artery	Coronary artery	Serum exosomes
			Sequest score			
1	P51662	Annexin A1	7700.9	10244.48	-	-
2	P33477	Annexin A11	1544.57	1157.06	-	-

The complex biochemical and mass spectrometry analysis are now in full progress. Aorta, coronary and carotid vascular fragments will be processed following the work flow shown in Fig.1. In parallel blood samples will be also analysed and the best candidates for molecular biomarkers will be validated by alternative methods (immunological, qPCR, immunohistochemistry). At least two scientific papers were in preparation to be submitted to peer review journals in the field.

2. Transnational collaboration

Describe the added value and synergies in the collaboration, any obstacles to the transnational collaboration, and the proposed solution (if necessary) (Max. 1 page).

The partner P2 appreciate very much the discussion we had with the CO in establishing the experimental model, in timing of harvesting the samples and the treatment delivery. The useful exchanging of ideas and significant references through the emails and regular skip meetings contribute to the adequate development of the project.

QUESTIONNAIRE / PROJECT IMPACT ASSESSEMENT

This questionnaire, to be filled by the project's coordinator, is part of the 2nd year's progress report (and is also included in the final report). It is for internal use by the ERA-NET ERA-CVD consortium in order to assess funded projects outputs. The results of this questionnaire will be presented in network meetings and included in public reports.

A. COMPOSITION OF THE CONSORTIUM

1. Please indicate the number and type of **entities** composing the consortium.

Type of entities	Total N°
Academia	2
Company	1
Clinical partner	1
Patient organisation	-
Other (Please specify: ……)	-

Add lines as appropriate

2. Please indicate the composition of the consortium in terms of gender balance.

Partner P1: ICBP N Simionescu	Total N° : 8
Females	6
Males	2

B. EXPECTATIONS VERSUS ACHIEVEMENTS

For each of the following areas, please rate to which extent (high, medium, low) you feel your project was expected to contribute and to what extent it has been contributing:

	Expected			Achieved		
	High	Medium	Low	High	Medium	Low
Scientific knowledge in some specific field	x			x		
Applied research and/or proof of concept	x			x		
Translational Research		x			x	
Impact on public health	x				x	
Research networking	x			x		
Training and capacity building	x			x		
Other (Please specify: new job creation)	x			x		

C. SCIENTIFIC KNOWLEDGE - PUBLICATIONS AND COMMUNICATIONS (after starting the project)

In the following tables, please list the **joint publications** and **communications** (in which ERA-CVD support was acknowledged) that resulted from the funded project (with at least two partners involved), underlining the name of the partners. In column "Partner(s) involved", please point out the project partners involved by using the numbering employed in the project proposal (e.g. partner 1 or P1).

1. Master and PhD theses

Master/PhD	Authors, title, year	Partner(s) involved
Master degree (2018-2020)	Aurel CERVEANU-HOGAS, Proteomic changes in carotid arteries induced by a hyperlipidaemia diet in New Zeeland White Rabbits, 2020	**P1**

Add lines as appropriate

2. Communications in scientific congresses

Authors, title, meeting name & place, year	Partner(s) involved	Type of presentation (Oral Communication/ Poster)
- Felicia Antohe. Toward precision medicine on the road from cell receptors to cell proteomics. The 40th ICBP NS Anniversary Symposium, Bucharest, 19-20 September 2019.	P1	Oral Communication
- Elena Uyy, Luminita Ivan, Viorel-Iulian Suica, Raluca Boteanu, Rune Hansen, Felicia Antohe. Alarmins expression in atherosclerotic lesions under severe anti-hyperlipidemic treatment; a mass spectrometry based proteomic approach. The 40th ICBP NS Anniversary Symposium, Bucharest, 19-20 September 2019.*	P1,CO	Poster
- Aurel Cerveanu-Hogas, Elena Uyy, Luminita Ivan, Viorel-Iulian Suica, Raluca Boteanu, Rune Hansen, Felicia Antohe. Mass spectrometric analysis of thoracic aorta alarmin profile in experimental atherosclerosis. 13th Central and Eastern European Proteomic Conference (CEEPC) Ustron, Poland, 23-25.09.2019.*	P1, CO	Oral Communication

-Viorel-Iulian Suica, Raluca Maria Boteanu, Elena Uyy, Luminita Ivan, Aurel Cerveanu-Hogas, Rune Hansen and Felicia Antohe. The proteomics of exosome alarmins as critical inflammatory players in coronary artery diseases.* 33rd World Congress on Cardiology and Heart Diseases, Prague, Czech Republic, 27-28.03.2020, (canceled event because of COVID 19).	**P1, CO**	**Poster**

D. USE OF SHARED RESOURCES/FACILITIES

1. Please indicate the number and designation of **shared resources** used within the framework of the current project.

Type of resources	Designation	Total N°
Existing cohorts		
Existing registries		
Biobanks		
Existing patient databases & corresponding biological material		
Innovative and shared technologies (e.g. OMICS, new generation	High performance LC/MS/MS tandem mass spectrometry proteomics	
Cellular and/or animal models	Experimental atherosclerotic New Zeeland White Rabbit model	40 males
Others (Please specify: ……)		

Add lines as appropriate

E. PUBLIC HEALTH IMPACT

1. Is the project expected to produce any result or finding that can be translated into a real impact on human health? YES

The project generated a list of alarmins highly expressed in the lesion in different stages of development that will represent a valuable asset for elaboration of clinical strategies for early detection and treatment of atherosclerosis. The best biomarkers will be selected to be used with the new multi-frequency ultrasound technology for improved evaluation and diagnosis of coronary plaque.

2. Has the project already produced any result or finding that can be translated into a real impact on human health? YES

Direct demonstration of proteome changes of the atherosclerotic lesions in different stages of development of the diseases that will be included in ProteomeXchange Consortium via the PRIDE partner repository data sets, free to be used by anyone.

3. If the answer to the questions G. 1 and/or G.2 was "YES", please indicate in what field(s) the results generated within the framework of the current project are expected to impact?

- Prevention
- Prognosis x
- Diagnosis x
- Therapy

4. Please list the major achievements of the consortium that can be translated into real impact on human health.

Achievements	YES/NO	Please specify (if YES)
Development of new preventive guidelines		
Development of new prognostic measures		
Development of new diagnostic products	Yes	List of alarmins up or down regulated in atherosclerosis, to be deposited in ProteomeXchange Consortium via the PRIDE partner repository international data sets.
Development of new diagnostic techniques	yes	Multi-frequency ultrasound technology for improved evaluation and diagnosis of coronary plaque.
Development of new diagnostic guidelines		
Development of new therapeutic products	yes	New alarmin biomarkers related to plaque progression
Development of new therapeutic techniques		
Development of new therapeutic guidelines		
Other achievements		

Add lines as appropriate

F. JOB CREATION

1. Please list below the number of **jobs** created within the framework of the current project (Pos-Doc fellowships & Contracts)

Partner #		Name	Gender	

	Type (Post-doc fellowship/ Contract)		**F**	**M**	**Duration of the fellowship/contract** months/years
ICBP NS	Master thesis and Research Assistant Contract	CERVEANU-HOGAS Aurel		x	Contract for at least 3 years

Add lines as appropriate

G. DISSEMINATION TO THE GENERAL PUBLIC

1. Which of the channels below were used to disseminate the results of the project to non-academic audiences and general public?

Dissemination channels	**YES/NO**	**Please specify (if YES)**
Project website	Yes	http://www.icbp.ro/static/en/en-networking_grants-grants-international/xplorecad.html
Presentations in non-scientific events, open days, etc.	Yes	Open access days of ICBP NS organised every year for young students to visit the research laboratories.
TV, Radio, Magazines, newspapers		-
Social Networks (twitter, linkedin, facebook, etc)		-
Internet (posting project news and communications in websites)	Yes	www.icbp.ro , P1 web site
Other channels		Central and Eastern European Proteomic Conference (CEEPC).

H. PARTNERSHIP AND CONSORTIUM SUSTAINABILITY

1. Did the partners of this project collaborate before applying for ERA-CVD joint transnational call (JTC)? YES

►If YES, please specify which partners (name, institution, country) were collaborating before and list the funding received (if applicable).

SINTEF (CO) and ICBP N.Simionescu (P1) collaborated previously in the MULTIBUBBLE (RCN FRINATEK, 2015-2018) project aiming to develop a new platform based on novel multifunctional nanoparticle-stabilized microbubbles and ultrasound technology for tergeted therapy of cancer and atherosclerosis.

2. Did you find any partners via the ERA-CVD Partnering Portal? YES/NO

►If YES, please specify which partners (name, institution, country) were found via the ERA-CVD Partnering Portal.

3. During the lifetime of the project, was there any new collaboration between any of the project participants and groups outside the consortium? YES/NO

►If YES, please specify which partners (name of researcher, institution, country) established new collaborations and with which groups (including other project consortia granted by ERA-CVD).

4. Has the participation in the project resulted in new scientific collaborations or partnerships between two or more of the project participants? YES

►If YES, please specify the partners (name, institution, country) involved.

The present collaboartion resulted in a new scientific research project with title: ***'A novel ultrasound-based therapeutic platform to enhance delivery of ApoA-1 encoding plasmid DNA for cardiovascular protection'*** by subitting a new applicationtion to The Norway Grants Call for Proposals 2019-Collaborative Reseach Projects with two Romanian partners and three colaborators from Norway:

CO: Felicia ANTOHE from Institute of Cellular Biology and Pathology N. Simionescu, Bucharest, Romania; **P1**: Runa HANSEN, from SINTEF AS, Trondheim, Norway; **P2**: Stefana PETRESCU, Biochemistry Institute, Bucharest, Romania; **P3**:Per SONTUM, Phoenix Solutions AS, Oslo, Norway; **P4**: Angelsen Bjørn, Surf Technology AS,Trondheim, Norway.

The project aim is, to improve the transfection rate of pDNA in the hepatocytes of the liver in order to obtain a systemic effect by elevating serum apoA-1 concentrations, affecting the cholesterol efflux and reducing the atherosclerotic burden, by combining ultrasound, microbubbles and liposomal pDNA.

Tissue engineering of blood vessels using three-dimensional bioprinting of endothelial and smooth muscle progenitor cells
PN-III-P1-1.1-PD-2016-1660, No. 19/2018 acronym BIOPRINT,
Phase report III-2020

Introduction

3D Bioprinting is a technique used for manufacturing tissues and organs that mimic the architecture of natural tissues. 3D bioprinting combines cells, growth factors and biomaterials to create a setting in which cells grow and differentiate into native tissue-like structures. In 3D bioprinting, biomaterials are printed layer by layer to produce structures similar to a desired organ or tissue. The first patent for this technology was proposed in the United States in 2003 and granted in 2006 [1]. Bioprinting involves several steps: (i) biomaterial selection, (ii) designing the bioprinting model/scaffold using CAM software, (iii) bioprinting the model using proper bioprinting technique, and (iv) analyzing bioprinting constructs [2]. In 3D bioprinting an exhaustive knowledge and methodology approach is needed from various fields such as engineering, stem cell biology, tissue engineering, and biomaterials science to create an ideal model [3]. An ideal scaffold should be biocompatible, non-immunogenic, non-toxic, anti-thrombotic, with vasoactive properties, allowing the remodeling of the scaffold post-implant by the host tissue. To create such a scaffold, physicochemical parameters such as geometry, pore size, surface properties, adhesion, degradation and biocompatibility should be analyzed [2-4]. Although there is a wide variety of biological materials, including synthetic polymers, hydrogels, extracellular matrix, cell aggregates, and microcarrier structures, several aspects have to be considered for obtaining structures similar to the target tissue. First of all, an important aspect is *compatibility* of biomaterials with different types of printing technologies. Extrusion printing is the most flexible method due to the simple mechanism and the larger diameters of printheads. Drop or laser printing is only used for hydrogels. The second aspect is the *bioprintability* of scaffolds. In this case, the bioprinting of hydrogels is superior to other bioinks. The third aspect is *replicability*, which implies that the constructs should be as close as possible to the desired tissue. Cell interactions and proliferation, scaffold degradation, are also important for tissue formation. The fourth aspect is related to the *bioprinting resolution*, which depends on bioprinting type as well as on bioink.

Laser bioprinting of hydrogels has a resolution of 5-10 μm, while the drop or extrusion bioprinting between 50-100 μm. The fifth aspect is *accessibility*. Matrigel ™, collagen and fibrin hydrogels are more expensive compared to synthetic polymers. In a scaffold, hundreds of millions of cells are needed so that obtaining them could be intensive, costly and time-consuming. Other aspects involve: *scalability, practicality, mechanical and structural integrity, degradability, commercial availability, immunogenicity* and *applicability*.

Despite the multitude of biomaterials that appear regular, relatively little research has been devoted to the development of biomaterials for the bioprinting process. Although a large number of hydrogels have great potential for tissue engineering, only a limited number can be used in bioprinting due to the lack of bioprintability and toxicity of degradation products. Also, the bioprinter parameters that should be optimized for each specific tissue. The main objectives for improving bioprinting are to minimize cell loss, promote cell-cell interactions, increase mechanical properties, and biocompatibility of 3D bioprinting scaffolds. Amniotic fluid cells are a heterogeneous population of mesenchymal cells of fetal origin of great importance in regenerative medicine. This population is known to have low immunogenicity, so it is less likely to generate an immune response thus having a high therapeutic potential [5, 6]. Phenotypes found in cell culture in amniotic fluid include epithelial-like and fibroblast-like cells [7]. There are also approximately 0.1-0.5% stem cells defined by c-kit expression (CD117+) on the cell surface. The regenerative potential of amniotic fluid-derived mesenchymal stem cells (AFSC) arises from their ability to differentiate and reduce immunogenicity [8]. AFSC can differentiate into different cell lines, such as endothelial [9], cardiac [10], neural, bone [11]. AFSC can also be reprogrammed without the use of gene transfer technology for induction of pluripotent stem cells [11]. The literature suggests a strong correlation between AFSC and the cardiovascular system. AFSC have demonstrated the ability to form capillary-like networks when grown in hydrogels and there is also evidence of paracrine signaling when AFSC are indirectly co-cultivated with human cardiac cells thereby modulating cardiac regeneration [12, 13].

Cardiovascular diseases are the leading causes of mortality worldwide and require over one million bypass / blood vessel replacements annually in the United States alone [14]. Although autologous vascular grafts are the gold standard for clinical use, they are not suitable for a large number of patients due to vascular disease, amputations or previous vascular tissue harvesting.

Despite the clear clinical needs of vascular substitutes, currently available synthetic grafts (for example, Dacron and Teflon) have proven to be successful only in large caliber implants; small diameter vascular substitutes (<6 mm) have generally unsatisfactory results, with major negative side effects, such as acute thrombosis, hyperplasia and aneurysm [15]. Arterial failures are generally attributed to the relatively low blood flow rate in these small vessels, which increases the rate of interactions between cells and molecules in the blood and polymeric implants. Therefore, there are strict requirements regarding the biofunctionality of the small diameter designed grafts. In order to produce grafts with normal vascular functions, at least 2 requirements must be met: (1) a confluent endothelium providing a nonthrombogenic interface and (2) a smooth contractile muscle tissue that can withstand haemodynamic stress and local changes in blood pressure that occur through constriction and physiological relaxation of the vessel [16]. Tissue engineering has emerged as a promising alternative approach for viable small diameter arterial grafts. Various strategies including decellularized tissue, synthetic polymeric matrices, self-assembling cell layers and hydrogels have been used to create living vascular structures and replace native blood vessels; these strategies have achieved different levels of success. These approaches generally produce vascular substitutes in the form of a robust tubular matrix containing smooth vascular or fibroblast muscle cells followed by seeding and cultivation of endothelial cells to achieve reendothelialization. This multi-step construction process is slow and requires complicated procedures and long manufacturing periods. In addition, grafting and retention rate of endothelial cells is strongly influenced by seeding mode, surface properties, cell density and culture conditions and, therefore, current methods can hardly be considered reliable for generating an intact functional endothelium. Therefore, biomimetic reconstruction of blood vessels through tissue engineering remains a difficult task that requires new construction techniques [17-20]. An important advantage of 3D bioprinting is the ability to build tissue / organ equivalents with a structure as close as possible to the native one. The precise positioning of cell-loaded bioinks simulates the anatomical features of the target tissue / organ, so that as cells proliferate, migrate and differentiate into a biomimetic construct. In particular, coaxial extrusion technique can use various biomaterials for bioprinting resulting in vessel-like structures [21].

For the successful bioprinting of a functional vessel, an essential factor is the bioink used. It must be biocompatible with the different cell types and promote the functionality of the cells and also allow the direct bioprinting of the vessels. While the hydrogels used to create vessels (fibrin, elastin, collagen, fibroin) generally have poor printability, materials suitable for co-extrusion bioprinting (alginate, gelatin methacryloyl, photopolymerized hyaluronic acid) usually have negative results due to low cellular affinity or poor mechanical properties and the functionality of the tissues is impaired. Despite significant improvements of current technologies to create three-dimensional (3D) blood vessels, the formation of a functional engineered vascular system with multiscale vessel networks from capillaries to large vessels has remained challenging in this field. Inability in fabrication of 3D vascular networks has limited tissue engineering in the growth of thick tissue or organ-level constructs [22].

The aim of this project was to create vascular structures using collagen and hyaluronic acid hydrogels and endothelial and muscle progenitor cells derived from mesenchymal stem cells isolated from amniotic fluid using 3D bioprinting.

1. Amniotic fluid stem cells differentiation and characterization

The amniotic fluid cell cultures (AFSC) were kindly provided by Genetic Lab S.R.L. diagnostics laboratory upon informed consent of the patients in agreement with national and EU rules. The primary cultures were obtained by centrifugation of amniotic fluid at 1050 rpm for 10 min. The cells were then cultured for 10 days without passages at Genetic Lab in AmnioMax medium, with medium change every 2 days (ThermoFischer Scientific, Waltham, Massachusetts, USA), then delivered to IBPC ‘‘N. Simionescu’’.

1.1. Cell culture and differentiation conditions

After 10 days primary culture was passage and cultured in differentiation specific media supplemented with growth factors. Endothelial differentiation of AFSC was done by cultured in M200 Medium supplemented with 10% FBS (fetal bovine serum), 40 ng/mL vascular endothelial growth factor (VEGF), 20 ng/ml insulin growth factor (IGF-1), 10 ng/ml epidermal growth factor (EGF), 10 ng/ml basic fibroblast growth factor (bFGF), 100 μg /mL penicillin, 100 μg/mL streptomycin, and 50 μg/mL neomycin (all purchase from Thermo Fischer Scientific, Waltham, Massachusetts, USA).

Smooth muscle differentiation of AFSC was done by cultured in M231 Medium supplemented with basic FGF (2 ng/ml), EGF (0.5 ng/ml), heparin (5 ng/ml), IGF (2 µg/ml) and bovine serum albumin BSA (0.2 µg/ml) (Thermo Fischer Scientific, Waltham, Massachusetts, USA). The cells were maintained in these media for 4 weeks, and passage when reached subconfluence. Cell cultures were maintained at 37 °C with 5% CO_2 and 21% O_2 in a humidified atmosphere.

1.2. Flow cytometry assay

Flow cytometry was used for the assessing the expression of cell specific surface markers (Gallios, Beckman-Coulter, California, SUA). AFSC ($1x10^5$ cells/marker) were stained with fluorochrome-conjugated (FITC - Fluorescein-isothiocyanate and PE - Phycoerythrin) primary antibodies against CD29 (integrin β1), CD31 (PECAM-1), CD49e (integrin α5), CD54 (ICAM-1), CD56 (NCAM), CD73, CD90 (Thy-1), CD105 (endoglin), CD146 (MCAM), and VEGFR2 (Beckman-Coulter). AFSC were detached using acutase (Sigma-Aldrich, St. Louis, MO, USA) and washed in phosphate-buffered saline solution (PBS). Cells were then incubated with the primary antibodies at room temperature in the dark for 30 min. Further, the cells were washed and centrifuged at 400g, 10 min, in PBS (Phosphate Buffer Solution) with 1 % BSA. For negative controls, AFSC were stained with the corresponding isotype-matched IgG antibodies (Beckman-Coulter, California, SUA). Flow cytometry data were analyzed using the Gallios software 1.0 (Beckman-Coulter, California, SUA).

1.3 Gene expression and functional characterization of endothelial progenitor cells (EPC)

Gene expression levels in AFSC and EPC were assessed by qRT-PCR. Total cellular RNA was isolated from cultured cells using RNeasy Mini Kit (Qiagen, Hilden, Germany) and reverse-transcription reaction was performed using M-MLV polymerase, High-Capacity cDNA Reverse Transcription kit (Thermo Fischer Scientific, USA). mRNA levels of endothelial associated genes (PECAM-1, ICAM-1, VE-Cadherin, eNOS and vWF) were quantified using TaqMan hydrolysis probes (ThermoFischer Scientific, Waltham, Massachusetts, USA). Quantitative Real Time-PCR reactions were carried out in a real-time thermocycler (ViiA7, Applied Biosystems, USA), following manufacturer's guidelines. The results were expressed using relative quantitation ($2^{-\Delta Ct}$), where ΔC^T represents C_T difference between values for AFSC and EPC.

Dil-Ac-LDL uptake assay. AFSC derived EPC were incubated with 6 µg/mL Dil-AcLDL-PE (Acetylated low-density Lipoprotein conjugated PE, ThermoFischer Scientific, USA).

Cells were incubated for 2 hours at 37 °C with 5% CO_2 and 21% O_2, washed with PBS and fixed with 1%PFA (paraformaldehyde) for 10 minutes at room temperature. **Ulex europaeus lectin (UEA) binding capacity to EPC**. For the assessment of Ulex europaeus agglutinin (UEA) binding capacity to EPC, cells were incubated with 0.01 mg/mL FITC – Ulex europaeus lectin (Sigma-Aldrich, St. Louis, MO, USA) for 2 hours, followed by a wash with PBS. The nuclei were counterstained with DAPI (1 mg/mL). The photomicrographs were taken with a digital camera Digital Net Camera DN100 using an Eclipse TE300 microscope (Nikon, Tokyo, Japan). **Matrigel vascular tubes assay**. To evaluate the formation of blood vessel networks in Matrigel, cells were seeded into 96-well plates at a density of 3,000 cells per well. Briefly, 50 µL of Matrigel (Sigma-Aldrich, St. Louis, MO, USA) was added in each well of a 96 well plates, and left to solidify for 30 minutes at 37ºC. After Matrigel polymerization, cell suspension was added and incubated for 4 hours. Tubes formation was observed using an Eclipse TE300 microscope (Nikon, Tokyo, Japan) equipped with a digital camera (Digital Net Camera DN100).

1.4 Gene expression and electrophysiological analysis of smooth muscle progenitor cells (SPC)

mRNA levels of muscular associated genes (smoothelin, calponin 1, α-SMA (α-actin), Myh11 (myosin heavy chain), α-tropomyosin, caldesmon-1, Cav3.1) were quantified using TaqMan hydrolysis probes (ThermoFischer Scientific, Waltham, Massachusetts, USA).

In patch-clamp experiments we used borosilicate glass capillaries (GC150F-10, Harvard Apparatus, USA) pulled with a PUL-100 equipment (WPI, Sarasota, FL, USA) and fire-polished with a home-made microforge to yield a resistance in solution between 2-3 MΩ. The patch-clamp setup included an inverted microscope placed on an antivibratory platform in a Faraday cage, a stage temperature controller (TC202A, Harvard Apparatus, MA, USA), a resistive feedback amplifer (WPC-100, ESF electronic, Göttingen, Germany) connected to a Digidata 1322A AD/DA interface controlled by the pClamp8.2 software (Axon Instruments, Molecular Devices, Sunnyvalle, CA, USA). Briefly, the extracellular solution was composed of: 135mM NaCl, 5.4 mM KCl, 1.8 mM $CaCl_2$, 0.9 mM $MgCl_2$, 0.33 mM NaH_2PO_4, 10 mM HEPES, 10 mM D-glucose pH 7.40 at 25°C titrated with NaOH. The pipette solution contained: 140 mM KCl, 5 mM EGTA, 10 mM HEPES, pH 7.21 at 25°C titrated with KOH. Multiple voltage protocols were applied, including: a general protocol for K^+ currents with depolarization steps from -60 to +60 mV with a duration of 300 ms from a holding potential of -80 mV; a double voltage ramp protocol (from -

120 mV to +80 mV in 2 s and back to -120 mV at the same time, from a holding potential of -70 mV) (I NS double-ramp); a protocol for voltage-dependent Na + currents with depolarization steps from -60 to +40 mV with a duration of 6 ms from a holding potential of -100 mV; standard protocol 2 of voltage-clamp for the separation of the current of Ca2 + type L from the current of Na + voltage-dependent. We applied the following pharmacological compounds: iberiotoxin 100nM (Alomone Labs, Jerusalem, IL), phrixotoxin-1 280µM, DIDS (stilbene disulfonate) 100 µM, mibefradil 10 µM, and nifedipine 1 µM (Sigma-Aldrich, St. Louis, MO, USA).

2. Design, bioprinting and characterization of blood vessel constructs using collagen-hyaluronic acid hydrogels and EPCs and SPCs

A computer-aided design (CAD) software (BioCad, RegenHU, Switzerland) was utilized to create the 3D models for bioprinting. A G-code series of instructions to be used by the 3D bioprinter (3D Discovery, RegenHU, Switzerland). The 2 printheads (one with bioink and EPC and the second with bioink and SPC, respectively) moved according to G-code instructions depositing bioink on circular slides. Bioprinting parameters were: 0.2 mm diameter needle, 1.2 bar extrusion pressure, 1 mm/sec printhead speed rate, 18ºC temperature. The diameter of vascular tubes was 2.5 mm, and thickness and height of each layer were 0.3 mm. A 5 seconds polymerization followed each bioprinted layer. The number of cells was 10 million cells/1 ml Coll-HA hydrogel. The amount was sufficient for printing 10 constructs.

2.1 Hydrogel preparation

Collagen hydrogel (H0) containing 2% peptides (collagen) used was purchased from RehenHu (Villaz-St-Pierre, Switzerland). Using this hydrogel, we developed other 2 hydrogels (H25, H50) by adding hyaluronic acid (MW 1-1.6 MDa, 1%, Sigma-Aldrich, St. Louis, MO, USA) in 2 different proportion, 25% and 50%, respectively.

2.2. Fourier-transform infrared spectroscopy (FTIR), Thermal gravimetric analysis (TGA) and Scanning Electron Microscopy (SEM)

FTIR spectra were recorded with a Nicolet iS50R spectrometer, at room temperature, in the measurement range 4000–400 cm^{-1}. Spectral collection was carried out in ATR mode at 4 cm^{-1} resolution. For each spectrum, 32 scans were co-added and converted to absorbance using OmincPicta software (Thermo Scientific).

The thermogravimetric measurements were made on a TGA 851e from Mettler−Toledo. The microbalance has a precision of ±0.1 mg and was kept at constant temperature (22 °C) during analyses to avoid the variation of mass measurement with temperature. Samples with a mass between 1 and 3 mg were placed into 70 µL alumina pans. Samples were heated between 25 and 800 °C at 10 °C/min under air flow (50 mL/min).

SEM imaging was obtained using the following protocol. The constructs were washed with PBS and fixed in 2.5 % glutaraldehyde for 1 hour at room temperature. Glutaraldehyde was then removed, and successive dehydration was carried out in ethanol (40 %, 60 %, 70 %, 80 %, 90 %, and 100 %) for 10 minutes each. SEM analysis was performed on a HITACHI S2600N electron microscope, at 25 keV, on samples covered with a thin silver layer.

2.3 Water uptake

Water uptake was performed to demonstrate the hydrogel swelling behavior in the presence of PBS (phosphate buffer saline). Bioprinted constructs were weighted after printing, then immersed into PBS and weighed at 10 min, 30 min, 1hr, 2hrs, 4hrs, and 8hrs, respectively. The absorption rate was calculated according to the formula:

$$\text{Water uptake} = \frac{Ww - Wd}{Wd\ (g/g)} \times 100$$

where: Ww = construct weight after immersion in the fluid at time t; Wd = construct weight before immersion

2.4 Enzymatic degradation

Enzymatic degradation of the constructs was assessed using collagenase type I and hyaluronidase. Bioprinted vascular constructs were introduced into culture medium (control constructs) and in collagenase type I and hyaluronidase medium (10 µg/ml collagenase and 10 µg/ml hyaluronidase, Merck, New Jersey, USA) and then weighed at different intervals time (10 min, 30 min, 1hr, 2hrs, 4hrs, and 8 hrs). Weight loss was calculated using formula:

$$\%\ \text{Weight loss} = \frac{Wi - Wt}{Wi\ (g/g)} \times 100$$

where: Wi = construct weight in collagenase free medium; Wt = construct weight in collagenase type I medium

3. Characterization of blood vessel constructs populated with EPCs and SMPs

3.1 Viability, morphology and oxidative stress assays

EPCs and SMPs behavior at 7 and 21 days after bioprinting was evaluated using LDH, GSH, and MTT assays, as well as and SEM. Cellular viability after 7 days and 21 days was evaluated using an **LDH assay** (Pierce™ LDH Cytotoxicity Assay Kit, Thermo Fischer Scientific, Massachusetts, USA). Lactate dehydrogenase (LDH) is a cytosolic enzyme present in many different cell types. Plasma membrane damage is followed by the release of LDH into the cell culture media. LDH can be quantified by a coupled enzymatic reaction in which LDH catalyzes the conversion of lactate to pyruvate via NAD+ reduction to NADH. Diaphorase then uses NADH to reduce a tetrazolium salt to a red formazan product that can be measured at 490 nm. Briefly, 50µL of each sample medium was transfer to a 96 well plate and then add 50µL of Reaction Mixture. The plate was incubated at room temperature for 30 minutes protected from light. Then was added 50µL of Stop Solution to each sample well and mixed by gentle tapping. The absorbance was measured at 490nm and 680nm using TECAN Infinite M200 (Männedorf, Switzerland).

Cellular stress was evaluated using **GSH assay** (Glutathione Fluorescent Detection Kit, Thermo Fischer Scientific, Massachusetts, USA). Glutathione (GSH) is an antioxidant found in eukaryotic cells. Reactive chemical species can cause a drop in GSH levels either by oxidation or reaction with the thiol group. A change in GSH levels is important for assessing toxicological responses and can promote oxidative stress, potentially leading to apoptosis and cell death. The protocol followed the manufacturer specification, using a standard for absolute quantification. The fluorescent emission was read at 510 nm, with excitation at 390 nm using a TECAN Infinite M200 spectrophotometer (Männedorf, Switzerland).

The viability and proliferation were assessed using **MTT assay** (Vybrant® MTT Cell Proliferation Assay Kit, Thermo Fischer Scientific, Massachusetts, USA). The assay is a colorimetric method that allows quantitative assessment of proliferation, cell viability and cytotoxicity. The viable cells reduce yellow tetrazolium salt MTT (3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide) to a dark blue formazan via mitochondrial enzymes. Briefly, the constructs cultivated for 7 days and 21 days respectively in 24-well plates, were incubated with 15 µl Solution I (MTT) at 37°C for 4 hours. Solution II (containing solubilization agents SDS and HCl) was added and pipetted vigorously to solubilize formazan crystals. After 1 hour the absorbance was read at 570 nm (TECAN Infinite M200, Männedorf, Switzerland).

The cellular morphology and distribution were evaluated using SEM, following the protocol described under 2.2 materials and methods section.

3.2 ELISA and Griess assay

The secretion of VEGF A from the endothelial progenitor cells at 7 days and 21days of culture in the constructs was measured using Human VEGF ELISA kit (Sigma-Aldrich, St. Louis, MO, USA) according to manufactured protocol. Nitric oxide (NO) was measured spectrophotometrically at 548 nm using the Griess Reagent Kit for Nitrite Determination (Molecular Probe, Thermo Fischer Scientific, Massachusetts, USA).

3.3 Immunohistochemistry

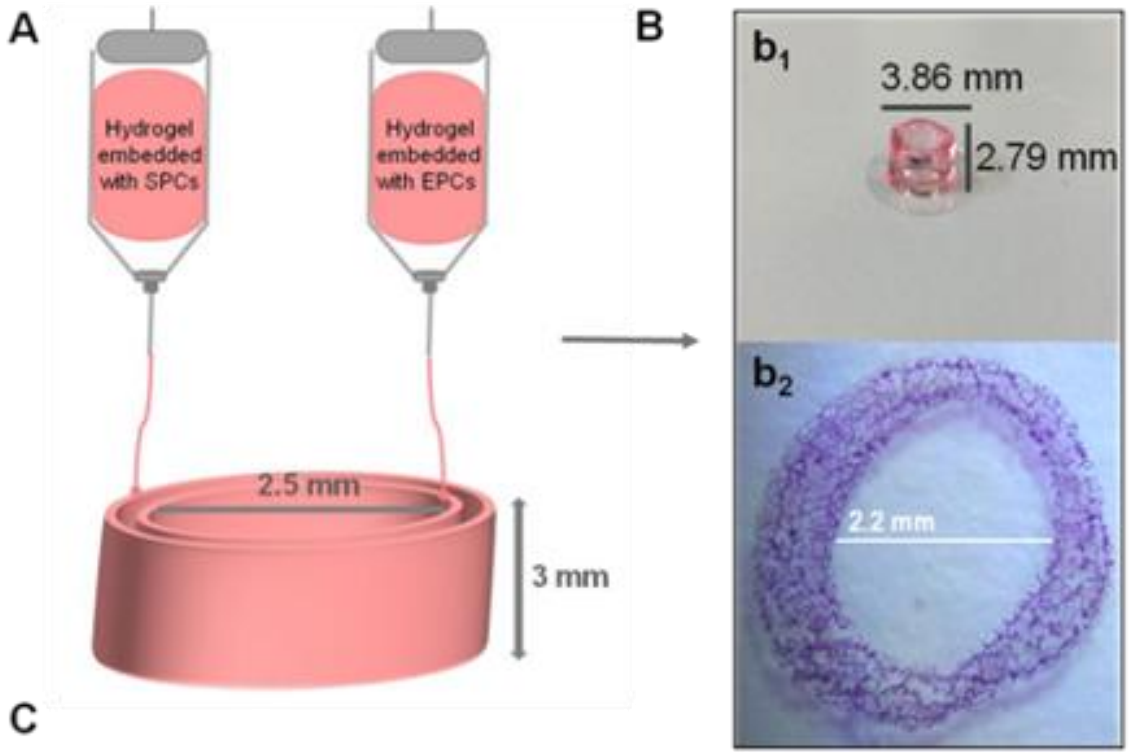
Immunohistochemistry was performed on 5 μm-thick cryosections on constructs at 21 days post-bioprinting. The sections were then incubated overnight, at 4°C, with the following primary antibodies: monoclonal mouse anti-human CD31 (1:250), CD144 (5 μg/mL), smoothelin (1:100), and anti-human μtropomyosin 1 (1:100) (Invitrogen, Thermo Fischer Scientific, Massachusetts, USA). The slides were washed three times with PBS, for 10 min., and then incubated for 2 hours at room temperature, with the secondary antibodies. The pictures were taken using an inverted microscope with an incorporated digital camera system for imaging (Olympus CKX41 equipped with Sense XC30 camera, Shinjuku, Tokyo, Japan).

Data analysis

Data are expressed as mean ± standard deviation (SD) or mean ± standard error of the means (SEM), as appropriate. In all instance's "n" signifies the number of cells analyzed in a certain experimental condition. Statistical analysis was performed using Student's t test or Fisher's exact probability test, using a critical level of $p < 0.05$. For immunophenotyping and gene expression profiling, statistical analysis was performed using the one-way ANOVA method for correlated samples.

Results and Discussions

The schematic diagram in Fig. 1A shows the bioprinting procedure. The vascular model was designed using the BIOCAD software. A 10-layer vascular construct having an internal diameter of 2.5 mm and a height of 3 mm was bioprinted using 2 printheads, one with Coll-HA hydrogel embedded EPC and second with Coll-HA hydrogel embedded SPC. After each layer, the polymerization module was inserted. The Coll-HA hydrogel polymerization was performed by exposure to UV for 5 seconds / layer. Working pressure has been established according to the physicochemical properties of the printed hydrogels. The optimal pressure was 1.1 - 1.2 bar (Fig. 1C). Printhead speed is a very important parameter for printing, and is dependent on the physico-chemical properties of the hydrogels. At a too high speed it does not close the vascular structure, and at a low speed it creates a thick layer that leads to the formation of a vascular construct over the desired size. The printing speed was set at 1 mm / sec using a needle with 0.2 mm internal diameter. For optimum printing, the hydrogels were printed at 18ºC, with the 3D bioprinter (3D Discovery, RegenHu, Switzerland) which have the possibility to adjust the printhead temperature. Using these parameters, were bioprinted vascular constructs with an internal diameter of 2.46 mm (± 0.41), wall thickness of 1.4 mm (± 0.10) and a height of 2.79 mm (± 0.05) (Figure 1B). These results show that the Coll-HA hydrogels can be used for vascular constructs and meet the desired requirements for reproduce with accuracy the model created in the BIOCAD software.



C

Needle diameter	Pressure	Printhead speed rate	Temperature	No of layers	UV	Diameter	Height
0.2 mm	1.2 bar	1 mm/sec	18°C	10	5 sec/layers	2.5 mm	3 mm

Fig. 1 Schematic diagram of bioprinting constructs (A) and optimal printing parameters of collagen-hyaluronic acid hydrogels based vascular construct (C). Macroscopic morphology (B, b_1) and H&E section of vascular constructs (B, b_2)

Other studies have shown that large wall thicknesses of vascular constructs may limit the transfer of oxygen and nutrients, while very small wall thicknesses would impair cells to align and spread reducing the mechanical strength [23, 24]. For these reasons, the nozzle made of a 0.2 mm internal needle was chosen for experiments, which were expected to meet both requirements for allowing sufficient nutrients diffusion and supporting cell growth. By optimizing the printer parameters, we continuously extruded smoothly hollow tubes with desired shapes and dimension.

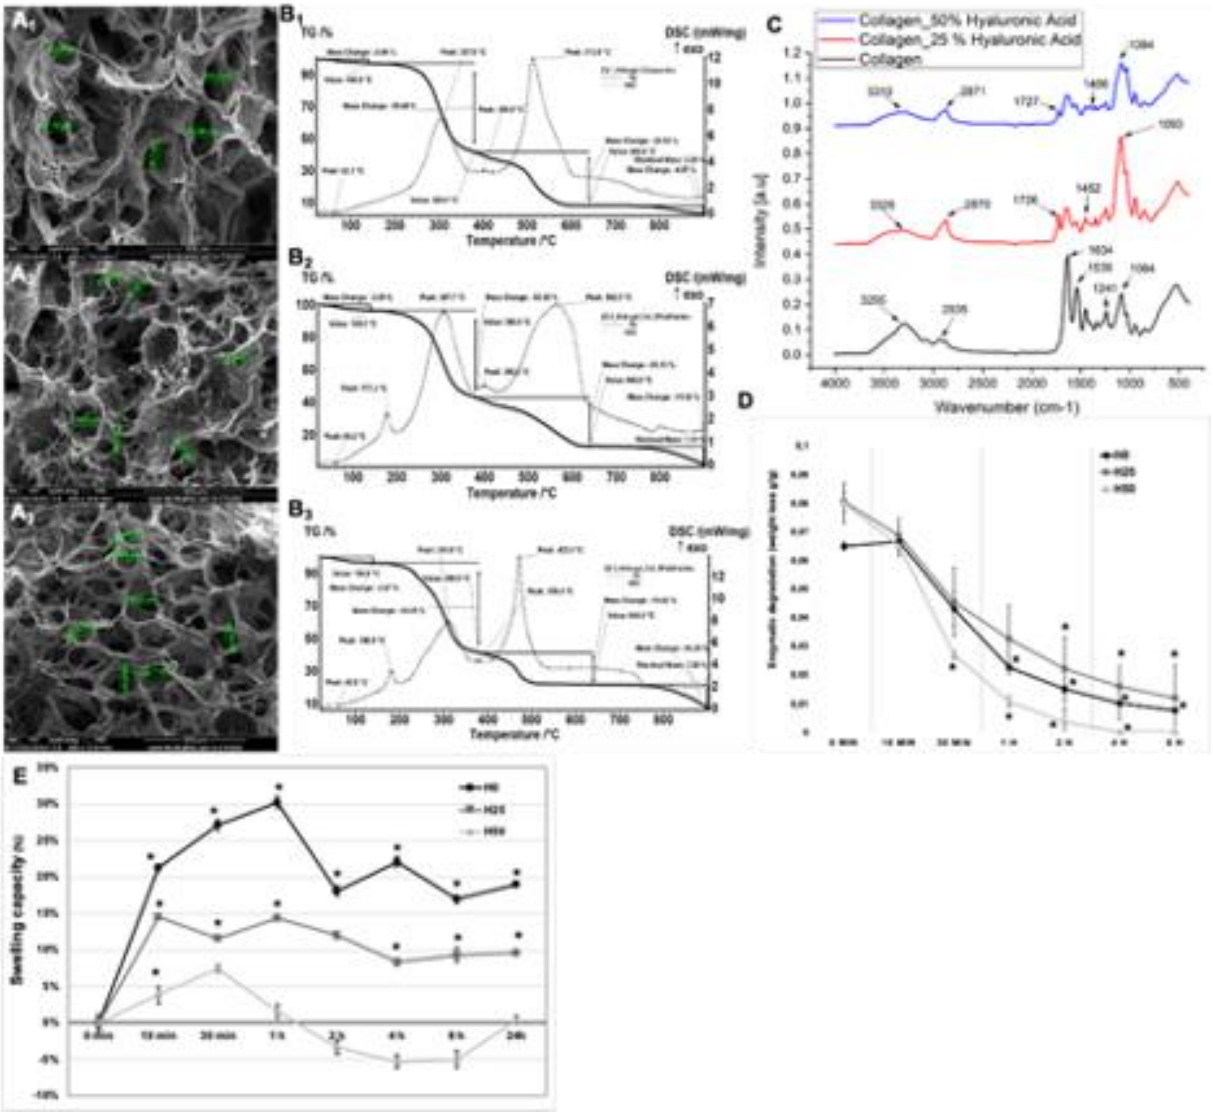


Fig. 2 Coll-HA hydrogels characterization by SEM (H0-A_1; H25-A_2; H50-A_3), TGA (H0-B_1; H25-B_2; H50-B_3), FTIR (C), enzymatic degradation (D), swelling capacity (E).

The morphology of Coll-HA hydrogels was assessed by SEM. The hydrogels present a characteristic porous morphology, the pore size was 107 µm ±23 µm for H0 hydrogel (Fig. 2 A_1), 51 µm ±20 µm for H25 hydrogel (Fig. 2 A_2), and 91 µm ±7 µm for H50 hydrogel (Fig. 2 A_3). The number and pore size are essential for cell growing, proliferation and adhesion, it has been considered that a pore size between 40-200 µm is appropriate to create an adequate microenvironment for cell development and tissue formation [25].

The hydrogel loses 2.66% of the mass in the RT-140°C interval, the process being accompanied by an endothermic effect with a minimum of 62.3^{o}C. In the interval 140-380°C the sample suffers a mass loss of 55.46%, the process being accompanied by a strong, wide exothermic effect, with a maximum at 307.8^{o}C. This is a process of oxidative degradation (parts of organic compounds are oxidized and at the same time chain breaks occur). In the range of 380-440°C there is a slower loss of mass, accompanied by a series of exothermic effects, superimposed, of lower intensity, indicating oxidation of some organic residues. Furthermore, the carbon mass remaining after oxidation undergoes a combustion process at CO_2 up to 640°C. This burning process is accompanied by an exothermic effect, very intense, slightly asymmetrical with a maximum of 513°C. The weight loss over the entire range is 33.53%. After 800°C the sample loses 4.87% of the initial mass, the residue representing 3.2% (Fig.2 B_1). The hydrogel with 25% hyaluronic acid is similar to the previous one, except for the exothermic effect at 177.3^{o}C, which could be due to a reaction that takes place between hyaluronic acid and collagen (Fig.2 B_2). The hydrogel with 50% hyaluronic acid also retains a higher mass of residue between 650-850°C (Fig.2 B_3), suggesting the role of hyaluronic acid in stability of hydrogels.

In order to determine the presence of the functional groups characteristic of the compounds used in the material synthesis, the FT-IR analysis was performed on the samples of collagen, collagen and 25% hyaluronic acid and respectively collagen and 50% hyaluronic acid. The spectrum obtained in figure 2C shows the absorption bands in the range 4000-400 cm-1.

The FTIR spectrum for the collagen hydrogel shows its specific absorption bands at 3295 cm-1 representing amide A and at 2935 cm-1 representing amide B. At the wave number 1634 cm-1 is present amide I characterized by the presence of groups C = O. 1539 cm-1 is the wave number assigned to amide II, where the vibration for the N-H and C-N groups is present, respectively. The case of the wave number 1241 cm-1 shows the appearance of amide III correlated with the C-N and N-H vibrations. The absorption band at 1084 cm-1 is characteristic of the tensile vibration of the C-O bond (Fig. 2C).

The presence of hyaluronic acid in the analyzed samples can be observed in comparison with the spectrum obtained for the collagen control sample.

The absorption band from approximately 3325 cm-1 (for the sample with 25% hyaluronic acid) and 3310 cm -1 (for the sample with 50% hyaluronic acid) is assigned to the OH and NH groups present in the structure of hyaluronic acid.

At the wave number of approximately 2870 cm^{-1} the vibration characteristic of the C-H group is observed. The value of the wave number of approximately 1400cm^{-1} is attributed to the COO- characteristic extent of the acid group in hyaluronic acid. At about 1080 cm-1 the C-OH group is highlighted. The spectra recorded for the hyaluronic acid samples indicate at the wave number of approximately 1726 cm^{-1} the presence of the carboxyl groups C = O (Fig. 2C).

Enzymatic degradation of the constructs was revealed using type I collagenase and hyaluronidase. Bioprinted vascular constructs were immersed in culture medium (control constructs) and in collagenase type I and hyaluronidase medium (10 μg / ml) and weighed at different intervals of time (10 min, 30 min, 1 hour, 2 hours, 4 hours, and 8 hours). The results showed a 33,8% weight loss at 30 minutes, followed by 34,6% at 1 hour, 76,9% at 2 hours, 84,6% at 4 hours and 88,4% at hours for collagen H0 construct (Fig. 2D). The H25 construct weight loss of 43,4 % of mass after 30 minutes, followed by 40,3% after 1 hour, 27,3% after 2 hours, 19% after 4 hours and 14% after 8 hours in the presence of collagenase type I and hyaluronidase. The most biodegradable construct was H50, after 4 hours entire construct was disintegrated in the medium (Fig. 2D).

The swelling capacity experiments showed that the H0 construct absorbs maximum of PBS at 1 hours after immersion, having a weight gain of 30,2% against the control construct. At 2-24 hours the values remain between 16-22%. In H25 construct swelling capacity is lower than in H0 construct, the maximum weight gain being 14,3% after 1 hour in the PBS (Fig. 2E). Furthermore, the H50 construct showed the lowest swelling capacity, with just 7,4% weight gain after 30 minutes in PBS (Fig. 2E). These results suggest that hyaluronic acid liberate water from the construct.

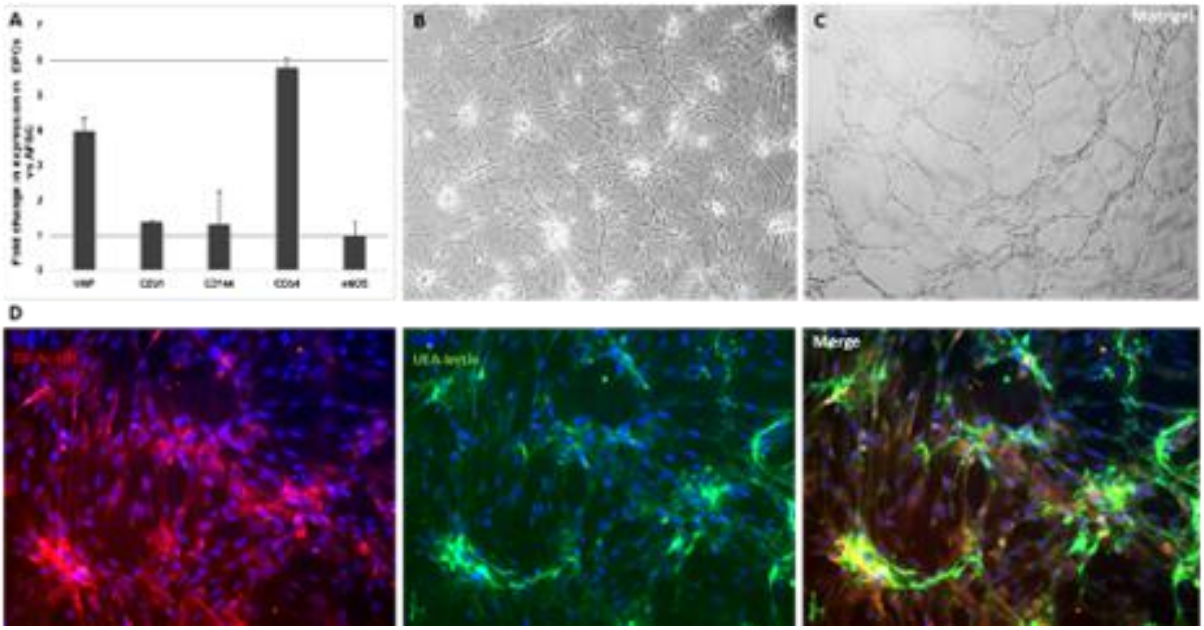

Figure 3. Characterization of differentiated EPC from amniotic fluid stem cells. A. qRT-PCR for detection of specific endothelial markers. B. Optical microscopy images of EPC cultures developed at 14 days in the presence of specific growth factors. C. Matrigel vascular tubes assay to evaluate the formation of blood vessel networks. D. Fluorescence images of EPC incorporating Dil-Ac-LDL and binding UEA-lectin.

Differentiation of EPC from AFSC was occurs after 10 days cultivation in endothelial specific medium supplemented with 40 ng/mL VEGF, 20 ng/ml IGF-1, 10 ng/ml EGF, and 10 ng/ml bFGF. After 10 days cells change the morphology from a fibroblast-like phenotype to an epithelia-like phenotype (Fig. 3B). The cells start to express endothelial specific markers such as vWF, CD31, CD144, CD54 and eNOS (Fig. 3A). The differentiate AFSC are capable to form vascular networks when are cultivate on Matrigel (Fig. 3C). Furthermore, these cells are capable to incorporating Dil-Ac-LDL and binding UEA-lectin (Fig. 3D), suggesting un endothelia cell phenotype.

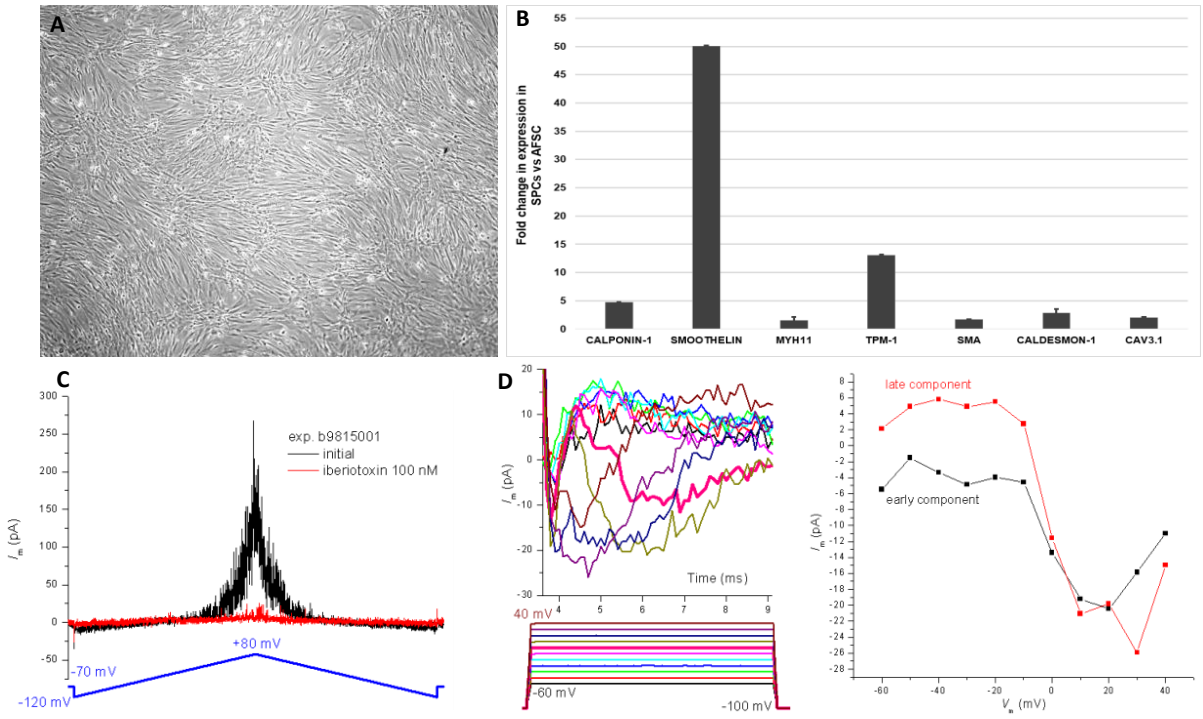

Figure 4. Characterization of differentiated SPC from amniotic fluid stem cells. A. Optical microscopy images of SPC cultures developed at 14 days in the presence of specific growth factors. B. qRT-PCR for detection of specific endothelial markers. C. Inhibitory effect of 100 nM iberiotoxin on BK current fluctuations at positive potentials, highlighted by a double-ramp voltage-clamp protocol. D. Inward current components suggestive of I_{CaT} and I_{CaL}

Differentiation of SPC from AFSC was occurs after 10 days cultivation in smooth muscle specific medium supplemented with FGF (2 ng/ml), EGF (0.5 ng/ml), heparin (5 ng/ml), IGF (2 µg/ml) and bovine serum albumin BSA (0.2 µg/ml). After 10 days in culture cells presents a specific morphology, with a fusiform shape (Fig. 4B). The cells start to express smooth muscle markers such as calponin-1, smoothelin, myh11, tpm-1, SMA, caldesmon-1, cav3.1 (Fig. 4B). Furthermore, using a double-ramp voltage-clamp protocol we demonstrate the presence of BK current fluctuations at positive potentials (Fig. 4C) and inward current components suggestive of I_{CaT} and I_{CaL} calcium channels (Fig. 4D).

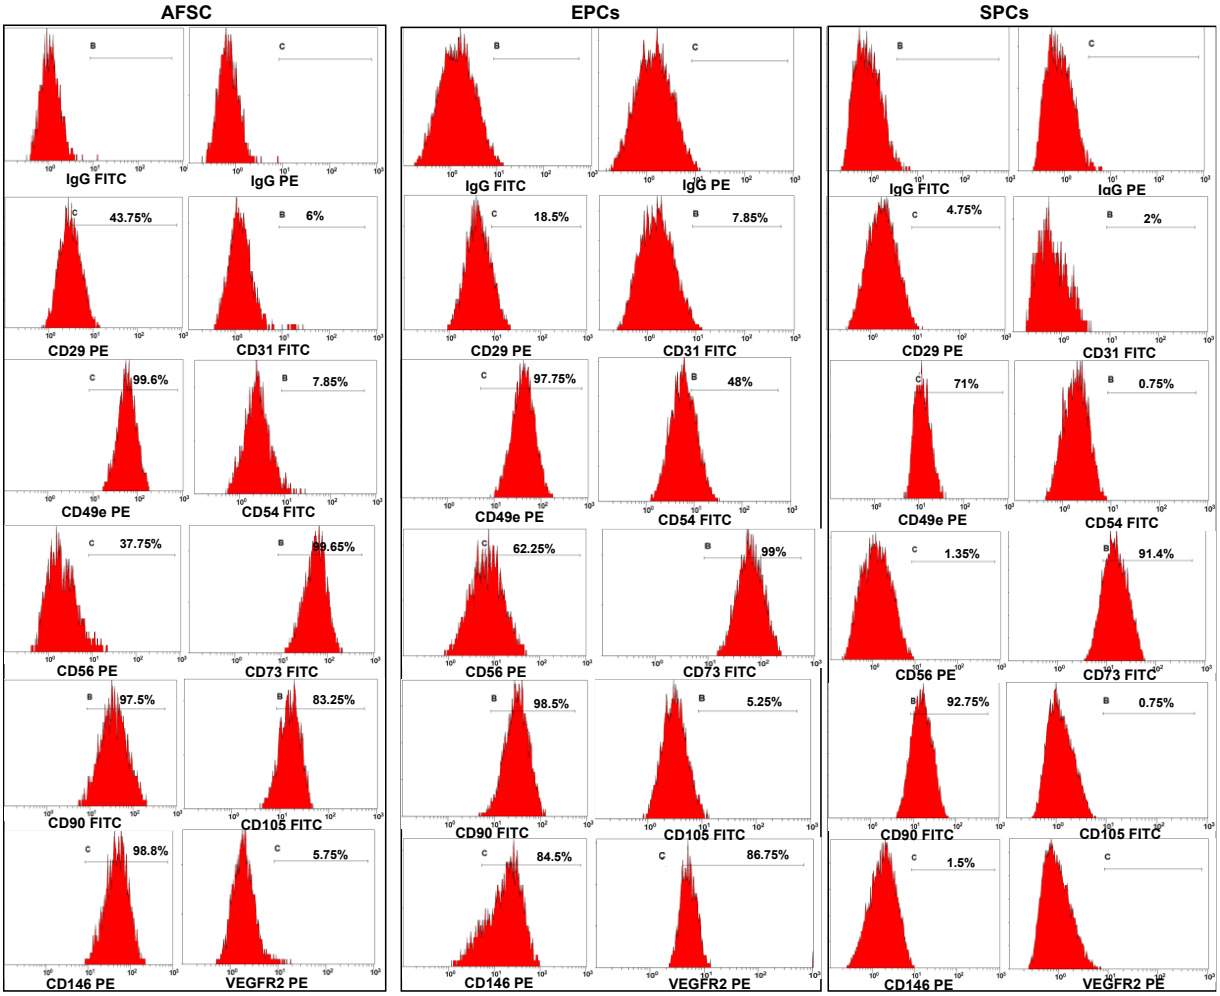

Figure 5. The immunophenotype of differentiated EPC and SPC from amniotic fluid stem cells after 10 day in the presence of specific growth factors

AFSC cultured in BIOAMF medium exhibits a mesenchymal phenotype characterized by surface markers CD29 (43,75%), CD49e (99.6%), CD54 (99,65%), CD56 (37,75%), CD73 (99.65%), CD90 (97,5%), CD 105 (83,25%) and CD146 (99,8%) (Fig. 5). CD29 is β1 integrin, associates with integrin α1 and α2 forming collagen receptors. It is expressed on the surface of mesenchymal cells and generally on the surface of the adherent cells where it binds the actin cytoskeleton with the extracellular matrix and transmits two-way signals between the extracellular matrix and the cytoplasm. Homing cellular adhesion molecule (HCAM) is a surface glycoprotein involved in cell-cell interactions in cell adhesion and migration.

CD44 may also function as a receptor for hyaluronic acid and may interact with other ligands such as osteopontin, collagen and matrix metalloproteinases. CD49e is α5 integrin which in combination with β1 integrin forms the fibronectin receptor. CD56 (NCAM) is part of the adhesion molecule family being neuronal cells. Data from the literature and previous results have shown that AFSC have an increased potential for differentiation in neural cells, so the medium in which they are cultivated and the duration of cell cultures is very important [13]. CD73 and CD90 are markers specific to mesenchymal adherent cells.

AFSC in the presence of EGM-2 medium supplemented with 40 ng / ml VEGF, 20 ng / ml IGF-1, 10 ng / ml EGF, 10 ng / ml βFGF showed the presence of endothelial cell-specific surface markers after 2 weeks. Flow cytometry assay revealed endothelial cell markers present on the surface of cells: CD31 (8%), CD54 (48%), CD146 (84,5%), VEGFR2 (86,75%) (Fig. 5). CD31 (platelet endothelial cell adhesion molecule) is a platelet and endothelial cell specific adhesion molecule involved in angiogenesis, vasculogenesis, integrin activation and leukocyte migration. Intercellular adhesion molecule 1 (ICAM-1) is an immunoglobulin family glycoprotein mediated on the surface of immune and endothelial cells, facilitating transmigration of leukocytes through vascular endothelium. CD105 (endoglin) is a protein involved in angiogenesis being found on the surface of vascular and endothelial progenitor cells.

AFSC growth in smooth muscle specific media, present only CD49e (71%), CD56 (91,4%) and CD73 (92,7%), suggesting a modification of protein expression towards a specific cell type (Fig. 5).

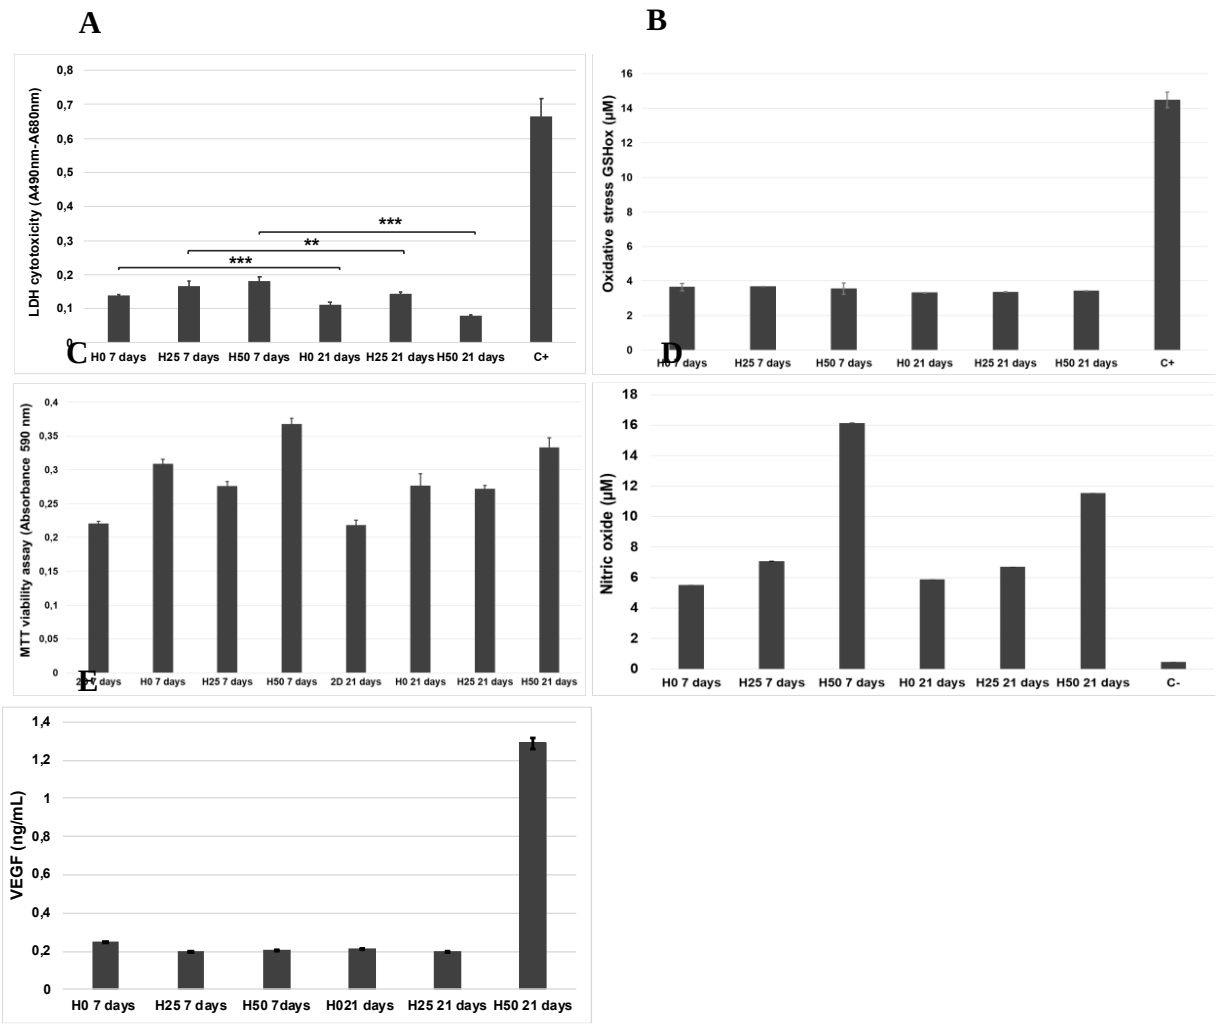

Figure 6. Characterization of blood vessel constructs populated with EPC and SMP. A. LDH viability assay, B. oxidative stress assays, C. MTT proliferation assay, D. Nitric oxide assay, E. ELISA assay for determination of VEGF

Characterization of blood vessel constructs populated with EPCs and SMPs was assessed using biochemical assays. EPC and SMP behavior at 7 and 21 days after bioprinting was evaluated using LDH, GSH, and MTT assays, as well as and SEM. Cellular viability after 7 days and 21 days was evaluated using an LDH assay. The results showed a low level of LDH compare to control suggesting that the cells remain viable in the constructs. At 7 days the highest level of LDH was observed for H50 construct, and after 25 days becoming the lowest (Fig. 6A). Cellular stress was evaluated using GSH assay. The level of GSH was between 3.33-3.69 µM, not statistical

significative compare with the positive control, suggesting that cells are not subjected to oxidative stress (Fig. 6B). The proliferation of the EPC and SPC was evaluated MTT assay. At 7 days post cultivation compare to the number of cells cultivated in plate (2D system), the cells in the H50 constructs presents a greater proliferation, followed by the cells in the H0 and H25 constructs. After 21 days the greatest proliferation was observed in H50 constructs, followed by H0 and H25 constructs (Fig. 6C). The level of nitric oxide (NO) was measured spectrophotometrically at 548 nm using the Griess Reagent Kit. The highest levels of NO were detected in H50 constructs, at 7 and 21 days, being 16,15 µM and 11,54 µM respectively (Fig. 6D). In H25 constructs the levels of NO were 7,8 µM and 6,7 µM at 7 days and 21 days of cultivation. The levels of NO do not change very much at 7 days and 21 day respectively for H0 constructs, being between 5,5-5,8 µM (Fig. 6D). The secretion of VEGF-A from the endothelial progenitor cells at 7 days and 21 days in culture was measured using VEGF-A ELISA kit. The highest level of VEGF-A was observed in H50 constructs, with a value of 1,29 ng/ml, followed by 0,25 ng/ml for H0 construct, and 0,25 ng/ml for H25 constructs (Fig. 6E). The results suggest that the cells are viable, with an active metabolism, and committed to EPC and SPC, being capable to secrete NO and VEGF.

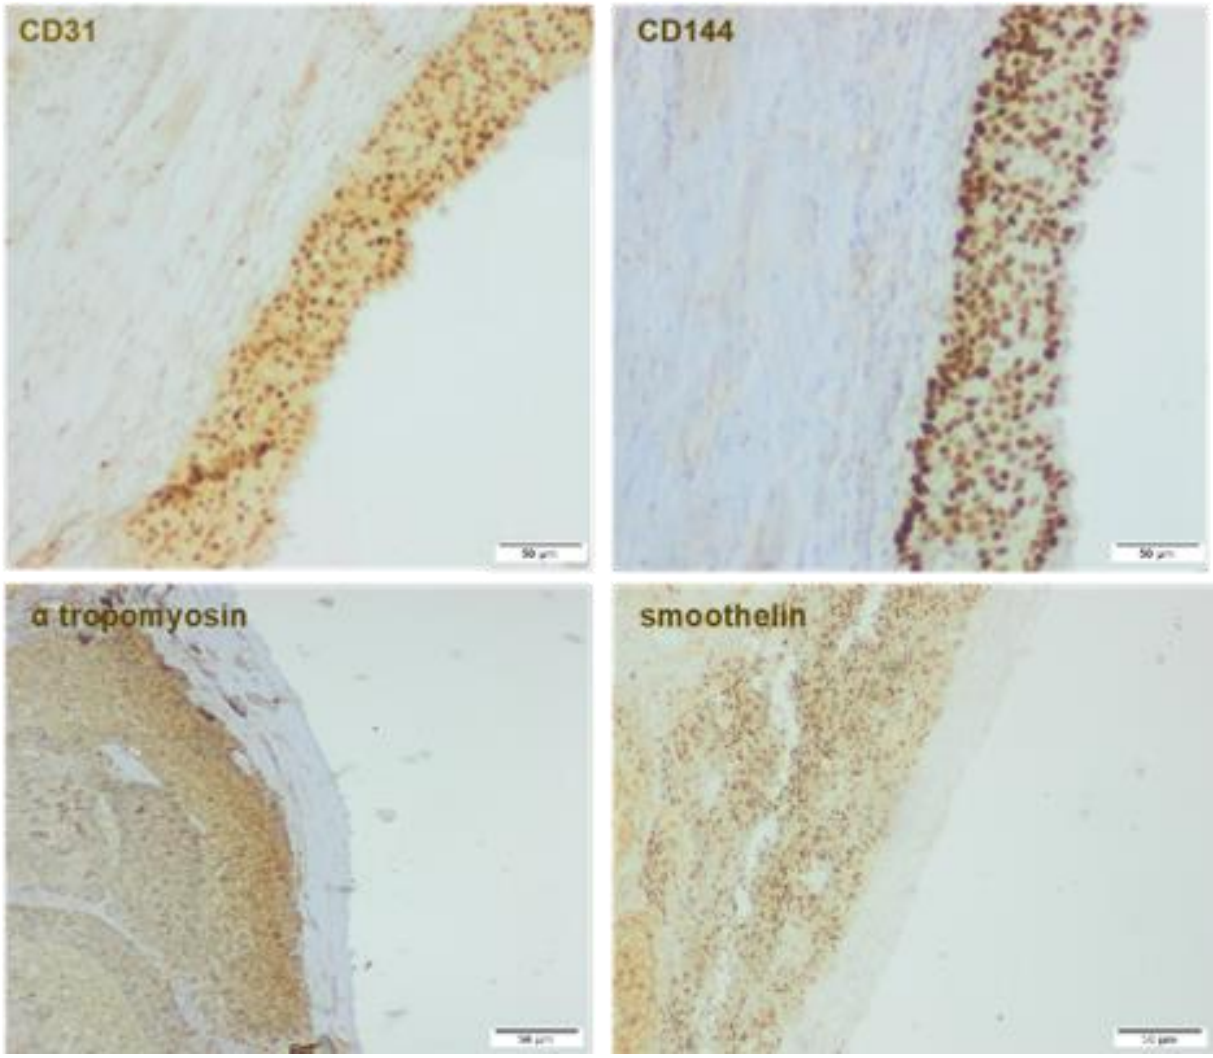

Figure 7. Immunohistochemistry of the constructs populated with EPC and SPC after 21 day in culture.

Immunohistochemistry was performed on 5μm-thick cryosections on constructs at 21 days post-bioprinting. The sections were then incubated overnight, at 4°C, with the following primary antibodies CD31, CD144, smoothelin, tropomyosin. The results showed that the cells expressed these endothelial and smooth muscle markers. Furthermore, immunohistochemistry images showed that the cells growth as they were bioprinted, observing the difference between external (muscle) layers, stained positive for tropomyosin and smoothelin and internal (endothelial) layers, stained positive for CD31 and CD144 (Fig. 7).

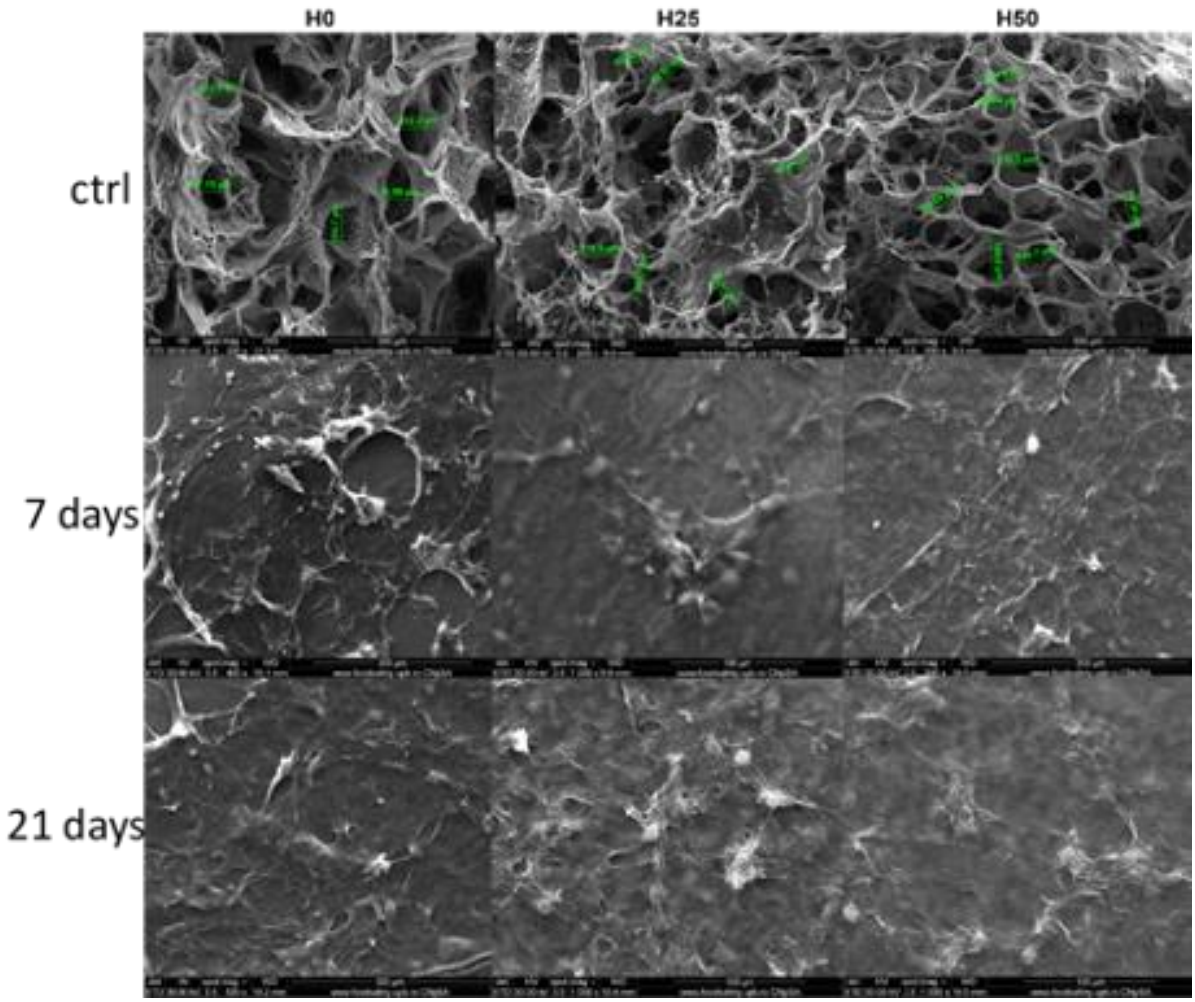

Fig. 8 Scanning electron microscopy images of H0, H25 and H50 hydrogels populated with EPC and SPC at 7 days and 21 days

The results showed that the cells adhere and distribute evenly in the collagen and hyaluronic acid hydrogels, which demonstrates the biocompatibility of these hydrogels. The H0 hydrogel has a porous structure, forms large pores with a diameter between 80-150 µM, H25 has smaller pores, between 40-120 µM and H50 between 80-150 µM. In the presence of the H0 hydrogel, the cells have a fusiform morphology and emit filopods that allow the cells to interact with each other and with the collagen fibres. The H25 and H50 hydrogels allow a good growth of cells, forming a rich extracellular matrix which allows a good adhesion and the possibility of organizing in a tissue (Fig. 8).

In conclusion, these results showed that the collagen/hyaluronic acid hydrogels allows the creation of the vascular constructs; the parameters of the 3D bioprinter have been optimized so that a vascular structure similar to the model developed in the BIOCAD program can be created. Amniotic fluid isolated cells are mesenchymal stem cells with potential for differentiation to endothelial and smooth muscle cells. The collagen-hyaluronic acid hydrogels are biocompatibile with the EPC and SPC. The obtained results showed that in the vascular structures created the cells are viable, proliferate and secrete factors necessary for the formation of blood vessels. The cells in the vascular structures express markers specific to the endothelial and muscular cells, suggesting the possibility of vascular graft formation.

Scientific Report (December 2019 - October 2020)

Project PN-III-P1-1.1-PD-2016-1942

"Evaluation of the therapeutic potential of non-viral apolipoprotein E gene transfer to limit progression of atherosclerosis"

In the period December 2019 - October 2020, in the project PN-III-P1-1.1-PD-2016-1942 entitled: „Evaluation of the therapeutic potential of non-viral apolipoprotein E gene transfer to limit progression of atherosclerosis", the experiments planned in the activity A3.1: „Evaluation of atherosclerotic plaques after systemic administration of apoE polyplexes in apoE-deficient mice" were performed.

Apolipoprotein E (apoE) has anti-atherosclerotic properties (facilitates the cellular cholesterol efflux) as well as anti-inflammatory and antioxidant properties. The majority of plasma apoE comes from the liver, but apoE is also synthesized by macrophages, spleen, lungs, kidneys, muscles and brain. The biological activity of apoE may be influenced by changes in its structure or quantity. A structural alteration is generated by the polymorphism of the APOE gene located on the long arm of chromosome 19, being described three alleles (ε2, ε3 şi ε4) encoding three isoforms: E2, E3, and E4, which differ in the amino acids present at positions 112 and 158. The frequency of the three alleles in the Caucasian population varies as follows: ε2 = 8-12%, ε3 = 74-78%, ε4 = 14-15%. E3 isoform is associated with normal lipid metabolism. ApoE2 has a low affinity for the LDL receptor, which leads to higher plasma levels of apoE, and in response, the liver increases the expression of LDL receptors resulting in lower cholesterol levels. Unlike apoE2, apoE4 has a more effective "clearance", which leads to lower plasma levels of apoE and higher cholesterol levels. In addition, apoE4 has been associated with Alzheimer's disease. ApoE deficiency is associated with atherosclerosis in both humans and mice. Systemic overexpression of apoE in mice induces hypertriglyceridemia, indicating that an optimal level of apoE protein in plasma is required for proper cholesterol removal.

In this project, we administered C60PEI-apoE3 polyplexes to atherosclerotic mice as a therapeutic agent to reduce the atherosclerotic process. In the first stage of the project, we obtained transfection agents based on C60-PEI polyplexes with apoE3 encoding DNA. Using molecular cloning methodology, we obtained five constructs containing apoE3 encoding DNA (the total sequence or several apoE fragments cloned into the pcDNA3.1-DYK vector) required for *in vivo* transfection. In the second stage of the project, the functionality of C60-PEI-apoE3 nanoparticles as *in vivo* transfection agents was tested after injections of mice with C60-PEI polyplexes and apoE3 encoding DNA. In the third stage of the project, atherosclerotic plaques were evaluated after systemic administration of C60-PEI-apoE polyplexes to apoE-deficient mice. ApoE-deficient mice were treated with a hypercholesterolemic diet throughout the period of administration of C60-PEI-apoE polyplexes. The amount of apoE protein in the serum of apoE-deficient mice treated with polyplexes was determined using the "Human ApoE ELISA development kit". For the "en face" evaluation of the atherosclerotic plaques, the mice's aorta were fixed with 4% PFA and stained with Oil Red O. To avoid using an excess of C60-PEI *in vivo*, the formation of polyplexes was optimized using DNA sequences encoding three fluorescent proteins (A7TagBFP, A8Cerulean or B7PA-GFP cloned in SalI and Eco47III sites of pEYFPC1 vector).

RAPORT ȘTIINȚIFIC FINAL - 2022

Titlul proiectului: Conceperea și sinteza unor compuși noi ai vanadiului pentru terapia diabetului; evaluarea preclinică într-un model experimental de diabet (DIAVAN)
Contract PN-III-P1-1.1-PD-2019-0247
Nr. PD 18/2020 (01.09.2020 – 31.08.2022)

Scopul proiectului **DIAVAN** este de a proiecta și sintetiza noi compuși pe bază de vanadiu ca medicamente insulino-mimetice și anti-diabetice potente.

Obiectivele proiectului **DIAVAN** sunt:

(OB 1) *Proiectarea, sinteza și caracterizarea de noi compuși ai vanadiului cu bază Schiff derivată de la aminoacizi;*

(OB 2) *Evaluarea potențialului noilor compuși ai vanadiului de a inversa rezistența la insulină indusă în hepatocite umane în cultură;*

(OB 3) *Studiul efectelor anti-diabetice ale noilor compuși ai vanadiului într-un model preclinic de șoarece cu diabet de tip 2 și rezistență la insulină.*

Indicatori de realizare: În cadrul proiectului DIAVAN au fost îndepliniți toți indicatorii de realizare propuși, astfel:

- Pentru **OB 1**, care a fost implementat în **etapa 1 (septembrie – decembrie 2020)** a proiectului, au fost sintetizate 3 noi combinații complexe ale vanadiului prin coordinarea bazei Schiff derivate de la aminoacidul valină și diferiți derivați de benzaldehidă (*o*-vanilină, salicilaldehidă) la centrii de vanadiu. Compușii au fost caracterizați fizico-chimic prin metode cristalografice și spectroscopice și li s-a determinat capacitatea de a se lega de proteinele serice și stabilitatea în medii biologice.
- Pentru **OB 2**, implementat în **etapa 2 (ianuarie – decembrie 2021)**, s-a evaluat toxicitatea noilor compuși ai vanadiului asupra liniei de hepatocite umane (HepG2) în cultură și efectul lor terapeutic. Doi dintre noii compuși dezvoltați prezintă activitate insulino-mimetică și de reversare a rezistenței la insulină. Aceste proprietăți au fost evidențiate prin cuantificarea moleculelor implicate în semnalizarea insulinei, glicoliză și metabolismul lipidic, folosind tehnici imunologice și colorimetrice.
- Pentru **OB 3**, implementat în **etapa 3 (ianuarie – august 2022)**, s-a determinat *in vivo* activitatea anti-diabetică a celui mai potent insulino-mimetic, stabilit în OB 2, prin utilizarea modelului de șoarece cu diabet de tip 2 și rezistență la insulină (IR-T2DM). Pentru aceasta s-au măsurat nivelurile de glucoză, insulină, lipide, markeri hepatici și renali din sânge și/sau urină și conținutul de lipide din ficat, folosind tehnici imunologice, colorimetrice și de microscopie.
- Diseminarea rezultatelor s-a făcut prin pagina web a proiectului (http://www.icbp.ro/static/en/en-networking_grants-grants-national_grants/diavan.html), prin publicarea, în calitate de prim-autor, a trei lucrări în reviste indexate ISI (factor de impact mai mare de 4.76) și prin prezentarea sub formă de postere la 4 conferințe internaționale/naționale.

Rezultatele obținute în proiectul DIAVAN și impactul estimat:

În cadrul proiectului DIAVAN au fost sintetizate și caracterizate structural și spectral 3 noi combinații complexe ale oxidovanadiului(V) cu baze Schiff provenite de la aminoacidul valină (val) și derivați ai benzaldehidei (salicilaldehidă = sal și *o*-vanilină = van); [{$V^{V}O$(R-salval)(H_2O)}(μ_2-O){$V^{V}O$(R-salval)}] (**1a**), [{$V^{V}O$(R-vanval)(CH_3OH)}$_2$(μ_2-O)] (**2a**) și [$V^{V}O$(vanval)(CH_3O)]$_4$ (**3a**).

Experimentele realizate *in vitro* au reliefat următoarele:

(1) cele 3 combinații complexe nou sintetizate sunt stabile în mediile biologice și au o capacitate crescută de legare la albumina serică bovină;

(2) combinațiile complexe dinucleare ale oxidovanadiului(V) (**1a**, **2a**) sunt citocompatibile cu hepatocitele din linia HepG2 la concentrații de aproximativ 100 µM, pe când compusul tetranuclear (**3a**) este citotoxic având un $IC_{50} \approx 6$ µM;

(3) la concentrațiile non-citotoxice, combinațiile complexe dinucleare **1a**, **2a** prezintă efecte insulino-mimetice, evidențiate prin reducerea activității totale a PTP și creșterea fosforilării INS R, AKT și ERK în celulele HepG2;

(4) insulino-mimeticul **2a** crește răspunsul celulelor HepG2 rezistente la insulină (IR) la acțiunea hormonului insulină față de compusul **1a** sau medicamentul anti-diabetic metformină, evidențiat prin: creșterea preluării glucozei, amplificarea sintezei glicogenului și reducerea nivelurilor de lipide (trigliceride și colesterol) acumulate în celule;

(5) mecanismul prin care compusul **2a** reversează IR în celulele HepG2 implică: inhibarea expresiei PTP-1B, fosforilarea/ activarea INS R și a mesagerilor secundari precum AKT, ERK, diminuarea nivelurilor proteinelor implicate în homeostazia glucozei (G-6-Pase), metabolismul glicogenului (GSK3) și sinteza lipidelor (FAS și HMGCR) și prin creșterea nivelurilor GLUT4.

Studiile preclinice, care au utilizat șoarecii C57BL/6j, au arătat următoarele:

(1) insulino-mimeticul **2a** nu induce toxicitate șoarecilor la dozele testate (3.75, 7.5 și 15 mg/Kg corp șoarece);

(2) 2a este rapid preluat de către țesuturi și organe, cu precădere de rinichi și ficat;

(3) 2a are efecte anti-diabetice și de reversare a rezistenței la insulină, evidențiate pe modelul de șoarece cu diabet de tip 2 si rezistență la insulină, prin: reducerea nivelurilor de glucoză circulantă și excretată, normalizarea indicelui HOMA-IR, îmbunătățirea nivelurilor markerilor hepatici si renali, scăderea nivelurilor de lipide circulante și acumulate la nivel hepatic, depozitarea glucozei sub forma de glicogen și reducerea fibrozei hepatice induse de diabet.

Acest proiect inovator combină sinteza de noi compuși ai vanadiului și investigarea preclinică a potențialului lor anti-diabetic, pentru a dezvolta o nouă strategie terapeutică pentru tratamentul T2DM.

CONCEPEREA ȘI SINTEZA UNOR COMPUȘI NOI AI VANADIULUI PENTRU TERAPIA DIABETULUI; EVALUAREA PRECLINICĂ ÎNTR-UN MODEL EXPERIMENTAL DE DIABET [DIAVAN]

ETAPA 1 (01.09.2020 – 31.12.2020)

Dezvoltarea de noi compuși ai vanadiului derivați de la aminoacizi

Etapa 1 a proiectului DIAVAN își propune sinteza și caracterizarea fizico-chimică de noi compuși ai vanadiului cu baze Schiff derivate de la aminoacidul valină și derivați de benzaldehidă, precum salicilaldehidă și *o*-vanilină și evaluarea *in vitro* a solubilității/stabilității acestor compuși în soluții (în condiții fiziologice) și a capacității lor de legare la proteinele plasmatice.

Indicatorii de realizare a obiectivului corespunzător etapei 1 au fost îndepliniți în totalitate.

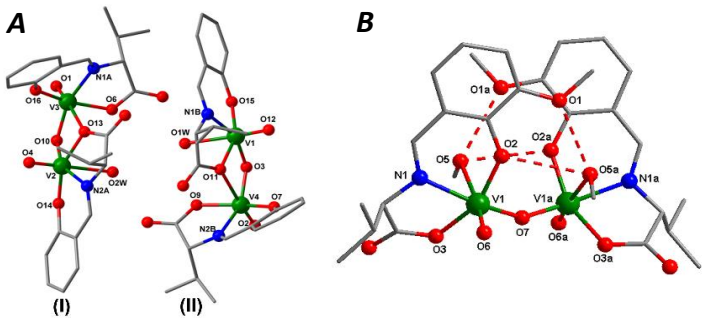
Rezultatele obținute în etapa 1 a proiectului DIAVAN sunt:

1) folosind o metodă simplă și eficientă, au fost sintetizați doi noi compuși ai vanadiului (V^V) și enantiomerii lor pornind de la sulfatul de vanadil, aminoacidul valină și salicilaldehidă/*o*-vanilină;

2) compușii de vanadiu sintetizați au fost caracterizați structural prin difracție de raze X pe monocristal și spectral prin spectroscopie optică (UV-Vis, FT-IR și dicroism circular). Datele structurale și spectrale au evidențiat că cei 4 compuși sunt dinucleari (V^V), având o geometrie octaedrică distorsionată. Aceștia sunt stabili din punct de vedere structural ca rezultat al stabilirii unor cicluri chelate de 5 atomi între ligandul de tip bază Schiff și centrii de vanadiu și mai mult ca rezultat al formării punților de hidrogen intra-/intermoleculare;

3) solubilitatea și stabilitatea compușilor de vanadiu(V) au fost estimate *in vitro* și datele obținute au evidențiat că aceștia prezintă solubilitate crescută în solvenți nepolari, precum DMSO și metanol și stabilitate moderat-crescută în condiții fiziologice;

4) combinațiile complexe ale vanadiului(V), sintetizate până în prezent, se leagă la proteinele plasmatice (albumină).



*(**A**) Unitatea asimetrică a compusului [{VO(R-salval)(H₂O)}(μ₂-O){VO(R-salval)}]. Moleculele independente sunt denumite I și II.*
*(**B**) Structura moleculară a compusului [{VO(R-vanval)(CH₃OH)}₂(μ₂-O)]. Salval = N-salicilidenvalină, vanval = 3-metoxi-N-salicilidenvalină.*

CONCEPEREA ȘI SINTEZA UNOR COMPUȘI NOI AI VANADIULUI PENTRU TERAPIA DIABETULUI; EVALUAREA PRECLINICĂ ÎNTR-UN MODEL EXPERIMENTAL DE DIABET [DIAVAN]

ETAPA 2 (01.01.2021 – 31.12.2021)

Evaluarea *in vitro* a proprietăților insulino-mimetice și de reversare a rezistenței la insulină a compușilor vanadiului nou sintetizați

Etapa 2 a proiectului DIAVAN își propune să evidențieze proprietățile insulino-mimetice ale compușilor vanadiului nou sintetizați și să evalueze *in vitro* efectul tratamentului cu insulino-mimeticul cel mai potent asupra rezistenței la insulină (IR). IR a fost indusă în hepatocitele din linia de carcinom hepatic uman (HepG2) prin expunerea lor la niveluri crescute de insulină/glucoză și a fost estimată prin urmărirea moleculelor cheie implicate în calea de semnalizare a insulinei, în glicoliză și metabolismul lipidic.

Indicatorii de realizare a obiectivului corespunzător etapei 2 au fost îndepliniți în totalitate.

Rezultatele etapei 2 a proiectului DIAVAN sunt:

1. combinațiile complexe di/tetranucleare ale oxidovanadiului(V) sintetizate în proiectul DIAVAN, dintre care trei nou dezvoltate, au o capacitate crescută de legare la albumina serică bovină;

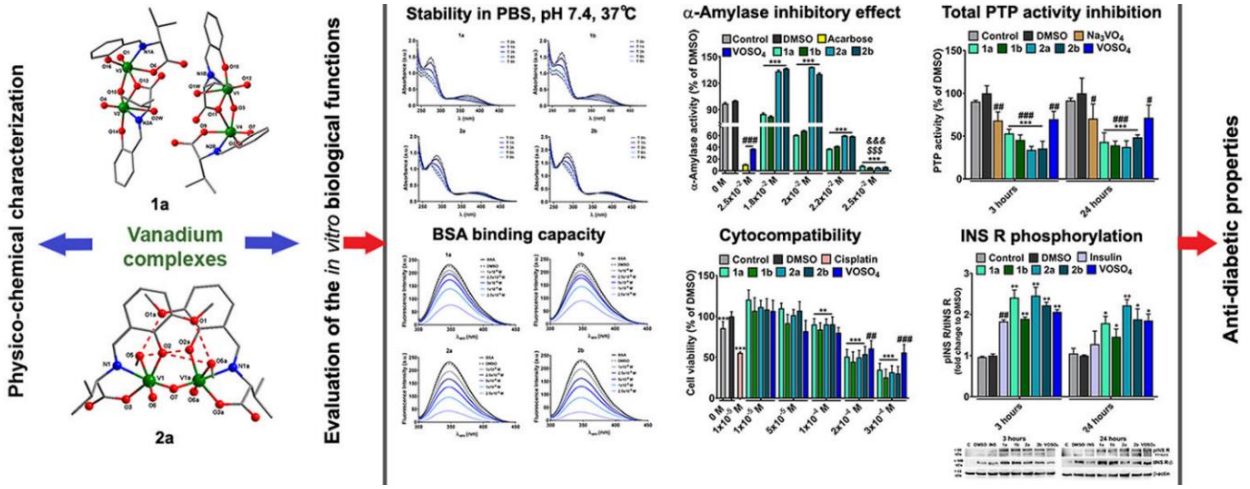
2. combinațiile complexe dinucleare ale oxidovanadiului(V) sunt citocompatibile la concentrații de aproximativ 100 µM;

3. la concentrațiile non-citotoxice, combinațiile complexe dinucleare prezintă efecte insulino-mimetice, evidențiate prin reducerea activității totale a protein tirozin fosfatazelor (PTP) și creșterea fosforilării receptorului pentru insulină (INS R), protein kinazei B (AKT) și protein kinazei reglate de semnalele extracelulare (ERK) în celulele HepG2;

4. modelul de IR *in vitro* a fost dezvoltat cu succes prin expunerea celulelor HepG2 la niveluri crescute de insulină;

5. compusul insulino-mimetic cel mai potent, ([{VO(R-van-val)(CH_3OH)}$_2$(μ_2-O)]), a favorizat creșterea răspunsului celulelor IR la hormonul insulină față de medicamentul anti-diabetic metformină, evidențiat prin: creșterea preluării glucozei, amplificarea sintezei glicogenului și reducerea nivelurilor de lipide (trigliceride și colesterol) acumulate în celule;

6. mecanismul prin care [{VO(R-van-val)(CH_3OH)}$_2$(μ_2-O)] reversează IR în celulele HepG2 implică: inhibarea expresiei PTP-1B, fosforilarea/activarea INS R și a mesagerilor secundari precum AKT, ERK, fosfoinozitol 3 kinaza (PI3K), diminuarea nivelurilor proteinelor implicate în homeostazia glucozei (glucoso-6-fosfataza, G-6-Pase), metabolismul glicogenului (kinaza sintazei glicogenului, GSK3) și sinteza lipidelor (sintaza acizilor grași, FAS; 3-hidroxi-3-metilglutaril CoA reductaza, HMGCR) și creșterea nivelurilor proteinei transportoare a glucozei (GLUT)4.



Proprietățile anti-diabetice ale complexelor de oxidovanadiu(V) cu baze Schiff derivate de la aminoacidul valină (val) și derivați de benzaldehidă, precum salicilaldehidă (sal) și o-vanilină (van). *1a = [{VO(R-salval)(H_2O)}(μ_2-O){VO(R-salval)}], 1b = [{VO(S-salval)(H_2O)}(μ_2-O){VO(S-salval)}], 2a = [{VO(R-vanval)(CH_3OH)}$_2$(μ_2-O)], 2b = [{VO(S-vanval)(CH_3OH)}$_2$(μ_2-O)], salval = N-salicilidenvalină, vanval = 3-metoxi-N-salicilidenvalină.*

Regulamentul Programului
“Bursa Maya si Nicolae Simionescu”
Perioada desfășurării: 8 iunie 2022– 7 iunie 2030

Motto: « Cercetare biomedicală fundamentală și aplicativă în beneficiul sănătății omului ».

Art 1 – Introducere

1.1. Programul “Bursa Maya si Nicolae Simionescu” își propune să identifice și sa finanteze realizarea unui proiect de cercetare în domeniul științelor biomedicale.

1.2. Programul este organizat și desfășurat de către Societatea Română de Biologie Celulară (denumită în continuare „SRBC”) si Institutul de Biologie si Patologie Celulară N. Simionescu, cu sediul în București, strada Bogdan Petriceicu Hasdeu, nr. 8, sector 5, reprezentat de către dna. Maya Simionescu, în calitate de Director (denumit în continuare „IBPC” sau „Organizatorul”).

1.3. La ediția 2023 a programului va fi oferită o bursă in valoare de 10 000 euro pentru un proiect de cercetare original si valoros a unui cercetător pentru consolidarea carierei științifice.

Art. 2 – Condiții generale de eligibilitate

2.1. Acordarea Bursei are ca scop sprijinirea unui proiect de cercetare care va fi desfășurat de câștigătorul Bursei (numit in continuare „Bursier”) pentru o perioadă de 1 an, în cadrul unei entitati de cercetare dezvoltare (cum ar fi, dar fără a se limita la**:** universitate, institut de cercetare, unitati de cercetare din cadrul unor instituții medicale) din România.

2.2. La Program poate participa orice persoană fizică română care îndeplinește în mod cumulativ următoarele condiții la data limită pentru depunerea rezumatului aplicatiei (1 iunie 2023):

i) La data depunerii rezumatului, 1 iunie 2023, are o vârstă care nu depășește 40 de ani;

ii) A obținut titlul științific de doctor în domeniile biologie/biofizica/științele naturii/medicina, menționate în comunicat și desfășoară activitate de cercetare în unul dintre aceste domenii;

iii) Nu are antecedene penale sau nu este în cursul unor investigații penale;

2.3. La Program nu pot participa membrii juriului.

Art 3 - Definiție și mod de utilizare a bursei

3.1. Definiție

3.1.1. “Bursa Maya si Nicolae Simionescu” este anuală, și constă în acordarea sumei de 10 000 euro caștigătorului competiției.

3.1.2. Contravaloarea bursei este data direct câștigătorului competiției, în două tranșe egale: prima tranșă va fi virată în termen de 30 de zile de la data începerii de către câștigătorul Bursei a activității de cercetare susținută prin intermediul Programului. A doua tranșă va fi virată până la împlinirea a 6 luni de la începerea activității de cercetare.

3.1.3. Bursa poate fi combinată cu alte indemnizații: alte donații, salariu și finanțare pentru post-doctorat.

3.1.4. Castigatorul Bursei trebuie să înceapă activitatea de cercetare în cel mult o lună de la data semnării contractului de acordare a Bursei.

3.2. Utilizare

3.2.1. Bursele sunt destinate proiectului de cercetare și nu pot fi folosite pentru a procura echipamente de bază de laborator.

Câteva exemple de utilizare:

- Achiziționarea de substanțe, consumabile si materiale necesare implementării proiectului. Achizitionarea de echipamente informatice.
- Finanțare pentru participarea la conferințe, congrese, etc.
- Taxe de publicare.

3.3. Castigătorul Bursei va avea obligația să realizeze activitatea de cercetare propusa pe parcursul a 12 luni.

3.4. Organizatorul nu își asumă nicio răspundere decurgând din acordarea Bursei, inclusiv cu privire la plata oricăror daune sau a oricărei alte pretenții de orice natură în legătură cu Bursa. Câștigătorul Bursei își asumă întreaga răspundere pentru acceptarea Bursei.

3.5. În cazul în care Organizatorul constată că Bursierul nu a îndeplinit și/sau nu a respectat condițiile stipulate de prezentul Regulament, Organizatorul își rezervă dreptul de a anula oricând drepturile și beneficiile ce revin acestuia în calitate de câștigător al Bursei, fără ca Organizatorul să datoreze acestui vreo despăgubire. În caz contrar câștigătorul va avea obligația de a restitui Organizatorului valoarea Bursei în termen de cel mult 3 luni de la data solicitării Organizatorului.

3.6. În cazul în care câștigătorul Bursei dorește să întrerupă temporar activitatea de cercetare susținută prin intermediul Bursei, acesta trebuie să obțină acordul prealabil în scris al juriului Programului cu privire la respectiva întrerupere. În caz contrar, precum și în cazul întreruperii definitive a activității de cercetare susținută prin intermediul Bursei, bursierul este obligat să returneze contravaloarea sumei primite cu titlu de Bursa. Juriul Programului își rezervă dreptul de a verifica veridicitatea și autenticitatea informațiilor înscrise în dosarul de aplicare.

3.7. În cazul în care Bursierul întrerupe temporar activitatea de cercetare susținută prin intermediul Bursei, din motive neimputabile (spre ex. dar fără a se limita la incapacitate fizică), acesta trebuie sa anunțe juriul Programului cu privire la respectiva întrerupere, urmând a se hotărî împreuna cu juriul Programului, de comun acord, reluarea și perioada reluării activității.

3.8. Bursierul va notifica în prealabil președintele juriului în cazul în care intervin schimbări în activitatea de cercetare sau în cazul retragerii din proiect. După primirea notificării, juriul va decide pe marginea acestor schimbări.

Art. 4 – Procedura de înscriere

4.1. Persoanele care doresc să participe la Program trebuie să trimită la adresa bursa.simionescu@icbp.ro :

- Etapa I. Cel mai târziu până la data de 1 iunie 2023, ora 23.59 **rezumatul proiectului** cu o temă originală din domeniul cercetării biomedicale **si CV – Europass** in limba engleza, în format .pdf;
- Etapa II. Cei selectionati in prima etapa vor trimite până la data de 15 august 2023 ora 23.59, proiectul de cercetare in extenso, în format .pdf, însoțit de documentele care alcătuiesc dosarul de candidatură:

a) Consimțământ pentru prelucrarea datelor cu caracter personal;

b) Curriculum vitae în format Europass incluzand lista de lucrari, carti publicate în tară și străinatate;

c) Copie buletin de identitate/carte de identitate;

d) Aplicația de proiect completată în formatul pus la dispoziție pe site-ul competitiei. Proiectul de cercetare cu o temă originală din domeniul cercetării biomedicale – « Cercetare biomedicală fundamentală și aplicativă în beneficiul sănătății omului » ;

e) Acordul conducerii instituției de învățământ acreditate din România/instituției de profil din România unde își desfășoară activitatea, pentru implementarea proiectului de cercetare propus (cu semnătură și număr de înregistrare);

f) Recomandare din partea unui specialist in domeniul bursei solicitate;

g) Copii ale actelor de studii: diplome (licență, studii aprofundate, doctorat), alte certificate de specialitate/diplome;

h) Adeverință medicală, eliberată de medicul de familie, care atestă faptul că persoana este declarată aptă pentru efectuarea stagiului de bursă;

4.2. Aplicațiile incomplete sau înscrierile ulterioare datelor menționate în regulament nu vor fi luate în considerare.

Art 5 – Mod de desfasurare si criterii de selecție

5.1. Mod de desfasurare

Selectia proiectului de cercetare se va desfasura in doua etape; prima (pre-selectia) implica predarea rezumatului proiectului si a unui CV al candidatului (si este eliminatorie) iar in a doua etapa, proiectele selecționate vor fi prezentate *in extenso*.

Solicitantul trebuie:

Pentru Etapa I – pre-selectia

• Sa redacteze rezumatul proiectului de cercetare propus, în maximum 500 de cuvinte (text justificat, font Times New Roman 12 cu spațiu 1.15). Rezumatul trebuie sa conțină următoarele secțiuni: *Titlul, Introducere, Ipoteza, Obiectivele, Originalitatea, Metodologia, Rezultate anticipate*. Rezumatul va servi la pre-selectia celor mai merituoase proiecte pentru Etapa IIa.

• Să prezinte un CV in care sa specifice experiența academica (numărul, calitatea și impactul publicațiilor, prezentările la conferințe, brevete etc.)

Pentru etapa II a Competitiei: proiectul *in extenso:*

• Sa descrie proiectul de cercetare in extenso, conform formularului de aplicatie incluzand cunostintele actuale in domeniul propus, metodologia, noutatea, relevanța și impactul cercetării. Descrierea nu trebuie să depășească 7 pagini inclusiv rezumatul (1 pagina) si referințele (1 pagina).

• Activitatea de cercetare propusa trebuie să contribuie la dezvoltarea cunoașterii în domeniu.

5.1. Criteriile de selecție aplicate de juriu sunt descrise in detaliu in Anexa 1.

Art. 6 – Desemnarea câștigătorului

6.1. Aplicatiile candidații vor fi evaluate de un juriu independent format din cercetători de prestigiu. Grila de evaluare și procentele asociate fiecărui criteriu sunt prezentate în Anexa 1. Decizia juriului este definitivă și fără apel. Nu poate fi contestată sau supusă explicațiilor sau justificărilor.

6.2. Numele câștigătorului Bursei va fi comunicat personal, prin mass media și pe site-ul http://www.icbp.ro/static/en/en-education_training/bursa_maya_si_nicolae_simionescu_2023.html

6.3. Pentru acordarea Bursei, câștigătorul trebuie să se prezinte, în termenul și la adresa care îi vor fi comunicate de către Organizator, în vederea acceptării Bursei, prin semnarea contractului de acordare a Bursei.

Bursierul va avea obligația să respecte și să se conformeze tuturor prevederilor, termenilor și condițiilor reglementate prin contractul de acordare.

6.4. În cazul în care, din orice motive neimputabile Organizatorului, Bursierul nu va semna contractul de acordare a Bursei, în termenul comunicat de Organizator, acesta va pierde calitatea de câștigător al Bursei și toate drepturile care decurg din această calitate. În acest caz, Organizatorul va putea decide fie să nu mai acorde Bursa, fie să acorde Bursa unui alte Participant ce va fi desemnat de juriul Programului.

Art. 7 - Calendarul competiției

7.1. Programul este organizat și se desfășoară pe teritoriul României.

7.2. Programul pentru anul 2023 începe la data de 2 mai 2023 și se încheie la data de 1 mai 2024.

7.3. Calendarul Programului:

- Lansarea competiției: 2 mai, 2023
- Data de depunere rezumat însoțit de CV: 1 iunie, 2023
- Rezultate evaluare etapa I: 30 iunie, 2023
- Data de depunere a dosarului, incluzand proiectului de cercetare: 15 august, 2023
- Anunțarea caștigatoarei/caștigatorului : 5 octombrie, 2023
- Inceperea proiectului si a finanțarii: 16 octombrie, 2023
- Finalizare proiect : 15 octombrie 2024.

7.4. In termen de 30 de zile dupa finalizarea proiectului, bursierul trebuie să prezinte juriului Programului un raport de maxim 5 pagini cu rezultatele activității la adresa bursa.simionescu@icbp.ro. De asemeni, bursierul va face o prezentare a realizarilor obtinute, in cadrul congresului anual al SRBC „Omagiu Profesorului „Nicolae Simionescu".

7.5. Bursierul se anganjeaza sa citeze suportul financiar acordat de bursa in publicatiile ulterioare in stilul "this research was made possible in part by financial support from the "Maya and Nicolae Simionescu" research fellowship (Number/year)".

Art. 8 – Interzicerea înlocuirilor

8.1. În cadrul Programului nu este posibilă înlocuirea Bursei oferite cu contravaloarea acesteia în alte beneficii. De asemenea, nu se permite înlocuirea Bursierului cu o alta persoană care să beneficieze de aceasta.

Art. 9 – Taxe și impozite

9.1. Impozitele sau orice alte costuri de natură fiscală sau de altă natură ce ar putea fi datorate în legătură cu Bursa vor fi în sarcina Bursierului.

Art. 10 – Protecția datelor cu caracter personal

10.1. Organizatorul prelucrează datele cu caracter personal ale participanților pentru scopurile și în condițiile prezentate în Anexa 2.

Ar. 11 - Reguli

11.1 Participarea la Program implică acceptarea acestui Regulament.

Art. 12 – Încetarea înainte de termen a Programului

12.1. Programul poate înceta înainte de termen numai în cazul apariției unui eveniment ce constituie forță majoră sau a unui alt motiv neimputabil Organizatorului, care îl pune în imposibilitatea de a continua Programul. O asemenea încetare va avea loc numai după anunțarea în prealabil a publicului prin intermediul site-ului.

12.2. În situațiile avute în vedere la alin. 12.1, Organizatorul nu va avea nicio obligație sau răspundere, de niciun fel, față de Participanți, privind returnarea unor sume și/sau plata unor sume cu titlu de despăgubire.

Art. 13 – Litigiile și legea aplicabilă

13.1. Eventualele dispute apărute între Organizator și Participanți se vor rezolva pe cale amiabilă.

13.2. Legea aplicabilă Programului și dispozițiilor prezentului Regulament este legea română.

Art. 14 – Diverse

14.1. Regulamentul este disponibil oricărei persoane interesate prin afișarea, în permanență pe durata Programului, pe site-ul accesibil la adresa:

http://www.icbp.ro/static/en/en-education_training/bursa_maya_si_nicolae_simionescu_2023.html.

14.2. Organizatorul își rezervă dreptul de a modifica sau înlocui prezentul Regulamentul în orice moment pe parcursul derulării Programului. Orice modificare sau înlocuire a Regulamentului vor fi anunțate în prealabil, prin publicarea pe Site înainte de data intrării în vigoare a respectivei modificări/înlocuiri.

14.3. Eventualele reclamații legate de derularea Programului se vor putea trimite către Organizator în termen de maximum 2 (două) zile de la data la care a luat naștere situația contestată. După această dată Organizatorul nu va mai lua în considerație nicio reclamație.

14.4. Reclamațiile referitoare la premiul câștigat, ulterioare momentului acceptării și primirii premiului de către persoana câștigătoare, nu vor fi luate în considere de către Organizator.

14.5. Deciziile Organizatorului privind Programul sunt definitive și aplicabile tuturor Participanților.

14.6. Premiile neacordate indiferent de motiv vor rămâne în posesia Organizatorului care poate dispune liber de acestea în maniera pe care o va considera necesară sau potrivită intereselor sale.

14.7. Organizatorul este îndreptățit să ia toate măsurile necesare în caz de tentativă de fraudă a sistemului, abuz sau orice alte tentative care ar putea afecta imaginea sau costurile pe care le implică organizarea și desfășurarea Concursului.

ORGANIZATORI:

Societatea Romana de Biologie Celulara / Institutul de Biologie si Patologie Celulara “N. Simionescu”

Anexa I - Criterii de evaluare

Etapa I		
Criteriu	**Descriere**	**Procent**
Rezumatul proiectului	Relevanța subiectului; obiectivul, scopul și motivația sunt clare	70%
CV	Experiența academica (numărul, calitatea și impactul publicațiilor, prezentările la conferințe, brevete etc.	30%
Etapa II

Consimțământul pentru prelucrarea datelor cu caracter personal
pentru candidații la bursa "Maya şi Nicolae Simionescu"

Subsemnatul/-a, _____, identificat/-ă prin B.I. / C.I. seria _____, nr. _____, eliberat/ă de _____, la data de _____, având C.N.P. _____, cu domiciliul stabil în localitatea _____, comuna _____, satul _____, str. _____, nr. _____, bl. _____, sc. _____, apt. _____,

în baza **Regulamentului U.E. nr. 679/2016**, *privind protecţia persoanelor fizice în ceea ce priveşte prelucrarea datelor cu caracter personal*, a **Legii nr. 129/2018** *pentru modificarea şi completarea Legii nr. 102/2005 privind înfiinţarea, organizarea şi funcţionarea Autorităţii Naţionale de Supraveghere a Prelucrării Datelor cu Caracter Personal, precum şi pentru abrogarea Legii nr. 677/2001 pentru protecţia persoanelor cu privire la prelucrarea datelor cu caracter personal şi libera circulaţie a acestor date*, a **O.U.G. nr. 41/2016** *privind stabilirea unor măsuri de simplificare la nivelul administraţiei publice centrale şi pentru modificarea şi completarea unor acte normative*, a **Legii nr. 190/2018** *privind măsuri de punere în aplicare a Regulamentului (UE) 2016/679 al Parlamentului European şi al Consiliului din 27 aprilie 2016 privind protecţia persoanelor fizice în ceea ce priveşte prelucrarea datelor cu caracter personal şi privind libera circulaţie a acestor date şi de abrogare a Directivei 95/46/CE (Regulamentul general privind protecţia datelor)*, referitor la:

1. Furnizarea către Societatea Română de Biologie Celulară a datelor mele cu caracter personal, așa cum sunt definite ele în legislația în vigoare:
□ sunt de acord
□ nu sunt de acord
2. Exprimarea consimțământului expres referitor la prelucrarea datelor după cum urmează:
a) furnizarea de către Societatea Română de Biologie Celulară a datelor mele cu caracter personal către persoanele implicate în organizarea și evaluarea pentru obținerea burselor în străinătate, a celor implicate în operațiunile financiar contabile legate de stagiul meu de bursă, în vederea bunei desfășurări a concursului pentru care am aplicat și / sau a stagiului de bursă pe care l-am obținut și îl efectuez/l-am efectuat:
□ sunt de acord
□ nu sunt de acord
b) preluarea de către Societatea Română de Biologie Celulară a datelor mele cu caracter personal, de la alte autorități sau instituții publice din țară și din străinătate în vederea bunei desfășurări a concursului pentru care am aplicat și / sau a stagiului de bursă pe care l-am obținut:
□ sunt de acord
□ nu sunt de acord
c) stocarea de către Societatea Română de Biologie Celulară a datelor mele cu caracter personal furnizate, în conformitate cu legislația în vigoare:
□ sunt de acord
□ nu sunt de acord
3. Afișarea publică a rezultatelor concursului organizat de Societatea Română de Biologie Celulară sunt de acord cu folosirea:

- numelui și prenumelui, așa cum apare în documentul de identitate

Am luat cunoștință de faptul că pot reveni oricând asupra acestui consimțământ, prin anunțarea prealabilă, în scris, a Societății Române de Biologie Celulară.

REGULAMENT

privind organizarea examenului de promovare pentru obținerea gradelor profesionale CSIII, CSII și CSI în cadrul Institutului de Biologie și Patologie Celulară "Nicolae Simionescu" al Academiei Române

Avizat,
Secția de Științe Biologice a Academiei Române

Capitolul I. Dispoziții generale

Articolul 1. Evoluția în cariera științifică a personalului de cercetare-dezvoltare, angajat în Institutului de Biologie şi Patologie Celulară „Nicolae Simionescu" (IBPC-NS) al Academiei Române, este asigurată şi realizată prin promovarea pe grade profesionale imediat superioare celor deținute.

Articolul 2. Promovarea se face prin examen organizat în conformitate cu prevederile Legii 53/2003 privind Codul Muncii, Legii 183/2024 privind Statutul personalului de cercetare-dezvoltare şi inovare (CDI), Ordinului Ministerului Educatiei Nationale şi Cercetarii ştiintifice nr. 6129/20.12.2016, Normelor metodologice privind organizarea examenului de promovare pentru obținerea gradelor profesionale de cercetare-dezvoltare, emise de către Academia Română la data de 15 iulie 2025 şi în conformitate cu prezentul regulament.

Articolul 3. Prezentul Regulamentul cuprinde metodologia privind organizarea examenului de promovare pentru obținerea gradelor profesionale de cercetare-dezvoltare superioare: CSIII, CSII şi CSI în IBPC-NS.

Articolul 4. Promovarea în grade profesionale a personalului CDI deja încadrat, se realizează prin transformarea postului ocupat într-un post imediat superior acestuia, corespunzător gradului profesional obținut prin examen.

Articolul 5. Cercetătorii ştiințifici din IBPC-NS se diferențiază pe funcții şi grade profesionale de cercetare-dezvoltare, păstrând echivalența cu gradele profesionale prevăzute în Carta Europeană a Cercetătorilor, după cum urmează:

(i) cercetător ştiințific gradul I (CSI), echivalent al cercetătorului senior principal R4, deținând

titlul de doctor;

(ii) cercetător ştiinţific gradul II (CSII), echivalent al cercetătorului senior consacrat R3, deţinând titlul de doctor;

(iii) cercetător ştiinţific gradul III (CSIII), echivalent al cercetătorului recunoscut R2, deţinând titlul de doctor;

(iv) cercetător ştiinţific (CS), echivalent al cercetătorului debutant R1, deţinând titlul de doctor sau având calitatea de student doctorand;

(v) asistent de cercetare ştiinţifică (ACS), echivalent al asistentului în activitatea de cercetare ştiinţifică, licenţiat.

Articolul 6. Numărul de posturi de CDI finanţate de Legea anuală a bugetului de stat este stabilit anual de Academia Română, care va aloca fila de buget în concordanţă cu aceasta şi cu aprobările Ministerului Finanţelor Publice.

Articolul 7. Examenul de promovare se organizează la decizia conducerii IBPC-NS în funcţie de resursele financiare disponibile şi de politica de resurse umane, cu încadrarea în bugetele aprobate şi respectarea prevederilor legale.

Articolul 8. Încadrarea pe posturi a personalului CDI se realizează prin concurs/examen, care este organizat pe baza următoarelor principii:

a. principiul transparenţei, competenţei, egalităţii de gen, nediscriminării şi accesul egal şi echitabil la ocuparea posturilor vacante, respectiv la promovarea în carieră pe un grad profesional imediat superior;

b. principiul asigurării calităţii şi pregătirii profesionale a personalului de cercetare;

c. informarea corectă şi completă privind organizarea şi desfăşurarea concursurilor/examenelor de promovare;

d. transparenţa cu privire la informaţiile administrative, financiare şi de evaluare a posturilor de cercetare conform legislaţiei în vigoare.

Capitolul II. Condiţii minime de pregătire

Articolul 9. Examenul de promovare se organizează la decizia conducerii IBPC-NS, ca urmare a solicitării persoanei care îndeplineşte prevederile Legii nr. 183/2024 privind condiţiile necesare înscrierii, alin. (10) şi (11) şi standardele minimale specifice fiecărui domeniu ştiinţific, alin. (1); dar şi standardele suplimentare stabilite în cadrul Institutului de Biologie şi Patologie Celulară "Nicolae Simionescu" al Academiei Române (Anexa SC).

Articolul 10. Criteriile în baza cărora sunt elaborate standardele minimale pentru ocuparea funcţiilor şi gradelor profesionale ale personalului CDI din IBPC-NS sunt următoarele:

a. rezultatele activităţii de cercetare şi/sau inovare;

b. impactul activităţii de cercetare şi/sau inovare;

c. capacitatea de a atrage fonduri de cercetare sau de a colabora cu organizaţii publice şi/sau private de cercetare;

d. prestigiul profesional;

e. capacitatea organizatorică;

f. capacitatea de cooperare internațională.

Articol 11. Standardele minimale pentru gradele profesionale de cercetare-dezvoltare stabilite de către Academia Română sunt:

(1) Pentru gradele profesionale CSII și CSI, standardele minimale sunt aprobate prin ordin al ministrului educației;

(2) Pentru gradul profesional CSIII, standardele minimale sunt următoarele:

a. să dețină titlul de doctor în specialitate sau în domenii conexe;

b. cel puțin cinci articole publicate în reviste indexate în *Web of Science – Core Collection*;

c. cel puțin o lucrare comunicată la o conferință internațională.

Articol 12. Standardele minimale necesare și obligatorii suplimentare stabilite de IBPC-NS pentru evaluarea activității profesionale a candidaților sunt prezentate în Anexa SC a Procedurii privind recrutarea, selecția și promovarea personalului CDI. Acestea sunt stabilite și aprobate în Consiliul Științific al IBPC-NS și nu derogă de la standardele minimale prevăzute de lege.

Articolul 13. Cercetătorii științifici CS, CSIII și CSII, care depășesc cu minimum 50%, cel puțin două treimi din standardele minimale proprii ale institutului, prevăzute la Articolul 12, pot susține examen pentru promovarea pe gradul profesional superior în IBPC-NS al Academiei Române cu care au contract individual de muncă pe perioadă nedeterminată, și pot fi promovați prin încheierea unui act adițional la contractul individual de muncă existent. Toate standardele minimale cuprinse în anexa prevăzută la Articolul 12 trebuie îndeplinite și 2/3 din standarde minimale proprii, oricare dintre ele, trebuie depășite cu minimum 50%.

Capitolul III. Desfășurarea examenului

Articolul 14. Calendarul de derulare a examenelor în IBPC-NS, în vederea ocupării posturilor vacante:

a. se întocmește cererea de înscriere la examen și se înaintează spre aprobare Consiliului Științific al IBPC-NS (Anexa 1P);

b. se realizează înscrierea la examen și depunerea dosarului de examen, în maxim 30 zile calendaristice, conform calendarului din anunțul pentru examenul de promovare, publicat pe site-ul institutului;

c. se întocmesc deciziile cu componența comisiei de examen/soluționare a contestațiilor și cu desemnarea președintelui de comisie;

d. dosarele de examen se transmit președintelui comisiei de examen, după înregistrarea și verificarea în prealabil de către secretarul comisiei de examen, în vederea analizei;

e. întreaga procedura de examen trebuie finalizată în termen de 15 de zile de la data încheierii înscrierii la examen, la nivelul comisiei de examen, și de 45 de zile, de la depunerea raportului comisiei de examen și a dosarului către Prezidiul Academiei Române;

f. în termen de maxim 2 zile de la comunicarea rezultatului, candidații au dreptul să depună contestație;

g. în termen de maxim 2 zile lucrătoare de la finalizarea examenului se comunică rezultatul final al examenului.

Articolul 15. Membrii comisiei de examen sunt cercetători ştiinţifici sau cadre didactice universitare cu gradul profesional sau titlul didactic universitar cel puţin egal cu gradul profesional pentru care se organizează examenul. Lucrările comisiei de examen sunt conduse de unul dintre membri comisiei, în calitate de preşedinte, numit prin decizie de către Directorul IBPC-NS. Componenţa comisiei este:

a. de 3 membri, în cazul examenului pentru CS şi CSIII;
b. de 5 membri, din care cel puţin 3 sunt din afara IBPC-NS, pentru CSII şi CSI.

Articolul 16. Examenul de promovare pentru obţinerea gradelor profesionale de CSIII, CSII şi CSI constă în:

c. *analiza dosarului de înscriere la examen* care trebuie să conţină documentele prevăzute în Anexa DP (se vor utiliza doar formularele-tip aprobate de IBPC-NS conform prezentului Regulament: Anexele 1P-5P întocmite conform modelelor propuse în Normele metodologice privind organizarea examenului de promovare pentru obţinerea gradelor profesionale de CDI din institutele Academiei Române/15 iulie 2025);
d. verificarea îndeplinirii condiţiilor prevăzute la Articolulele 11 şi 12;
e. acordarea punctajului pe bază de evaluare conform anexei prevăzute la Articolul 12.

Articolul 17. Rezultatele procesului de evaluare sunt consemnate de către fiecare membru al comisiei de examen în cadrul a câte unui referat de apreciere (Anexa 2E), în baza cărora preşedintele comisiei de examen întocmeşte un raport asupra examenului, semnat de fiecare membru şi propune acordarea gradului profesional de cercetare-dezvoltare candidatului respectiv.

Articolul 18. Consiliul ştiinţific analizează respectarea procedurilor stabilite prin regulament şi aprobă sau nu raportul asupra examenului, prin vot nominal deschis.

Articolul 19. Candidaţii la examen nemulţumiţi de rezultat, pot formula contestaţii care vor fi soluţionate în termen de 2 zile lucrătoare de la înregistrarea lor de către comisia de soluţionare a contestaţiilor, formată din:

a. preşedinte şi 2 membri cercetători ştiinţifici sau cadre didactice universitare, în cazul comisiilor de soluţionare a contestaţiilor înaintate în urma examenelor susţinute pentru ocuparea funcţiilor de execuţie în cercetare;
b. 3 membri, respectiv un membru din cadrul secţiei de specialitate a Academiei Române, Secţia de Biologie, care este şi Preşedintele comisiei, şi 2 membri din IBPC-NS având grad de CSI, în cazul comisiilor de soluţionare a contestaţiilor înaintate în urma examenelor susţinute pentru ocuparea funcţiilor de conducere în cercetare.
c. secretarul comisiei de soluţionare a contestaţiilor va fi numit din cadrul IBPC-NS prin decizie de către Directorul IBPC-NS.

Articolul 20. Comisia de examen şi comisia de soluţionare a contestaţiilor beneficiază de suport administrativ din partea organizaţiei de cercetare, asigurat de un secretar numit prin act administrativ al conducătorului organizaţiei de cercetare, care nu este membru al comisiei de concurs şi nu ia parte la deciziile comisiei. Formularele-tip utilizate de membrii comisilor, vor fi cele propuse şi aprobate conform prezentului Regulament (Anexele 1E şi 2E, întocmite conform modelelor propuse în Normele metodologice privind organizarea examenului de promovare pentru obţinerea gradelor profesionale de CDI din institutele Academiei Române /15 iulie 2025).

Articolul 21. Dosarele de promovare a examenelor pentru obținerea gradele profesionale de CSIII, CSII şi CSI se depun de către IBPC-NS în termen de 10 zile calendaristice de la finalizarea examenului la Secția de Stiințe Biologice a Academiei Române.

Capitolul IV. Rezultatele examenului şi încadrarea pe post

Articolul 22. În urma aprobării rezultatului favorabil al examenului desfăşurat în IBPC-NS de către Prezidiul Academiei Române, Preşedintele Academiei Române emite decizia pentru încadrarea pe post şi acordarea gradului profesional de cercetare-dezvoltare de CSIII, CSII şi CSI candidatului promovat, în conformitate cu prevederile art. 10 din Legea nr. 183/2024.

Articolul 23. După aprobarea rezultatelor examenului de promovare de către Prezidiul Academiei Române, dosarul se restituie IBPC-NS.

Articolul 24. În condițiile Articolului 4, dacă cercetătorul promovează examenul, acesta va fi încadrat pe postul aferent gradului profesional obținut prin examen, prin încheierea unui act adițional la contractul individual de muncă existent. Postul aferent gradului de cercetare superior rezultat din transformarea postului pe care îl ocupa persoana înainte de promovare este bugetat cel târziu începând cu anul următor celui în care s-a realizat promovarea, iar actul adițional la contractul individual de muncă se încheie începând cel târziu cu data de 1 ianuarie a anului următor celui în care s-a realizat promovarea prin examen, în baza deciziei eliberată de către Academia Română.

Articolul 25. Încadrarea pe posturi corespunzătoare funcțiilor şi gradelor profesionale ale personalului CDI se realizează conform principiului meritului profesional, în baza unor proceduri transparente şi echitabile care respectă principiile generale şi condițiile prevăzute de Carta Europeană a Cercetătorilor.

Articolul 26. Echivalarea funcțiilor didactice universitare cu funcțiile şi gradele profesionale CDI din IBPC-NS funcționează numai cu aprobarea Consiliului Ştiințific după evaluarea standardelor suplimentare adoptate în IBPC-NS.

Articolul 27. Datele cu caracter personal ale persoanelor implicate în procesul de examinare sunt prelucrate în cadrul platformei informatice, cu respectarea prevederilor Regulamentului (UE) 2016/679 privind protecția persoanelor fizice în ceea ce priveşte prelucrarea datelor cu caracter personal şi privind libera circulație a acestor date şi de abrogare a Directivei 95/46/CE (Regulamentul general privind protecția datelor).

Articolul 28. Un raport sintetic privind organizarea şi desfăşurarea examenului de promovare se întocmeşte la nivelul IBPC-NS dr către responsabilul resurse umane şi se transmite anual, în termen de 15 zile calendaristice de la finalul anului calendaristic pentru care se face raportarea, atât în format fizic cu adresa de înaintare, către Serviciul Programe de Cercetare şi Doctorat, cât şi în format electronic la adresa de email bpg@acad.ro.

Articolul 29. Anexele DP, L, 1P-5P, 1E şi 2E fac parte din prezentul Regulament şi împreună cu acesta, au fost stabilite şi întocmite de către IBPC-NS în conformitate cu reglementările şi modelele propuse de către Academia Română în cadrul Normelor metodologice privind

organizarea examenului de promovare pentru obţinerea gradelor profesionale de CDI din institutele Academiei Române/15 iulie 2025.

Prezentul Regulament a fost aprobat în şedinţa Consiliului Ştiinţific al IBPC-NS din data **07 August 2025**_. Acesta poate fi ajustat prin calibrarea oferită de examenele pentru fiecare categorie (grad ştiinţific) care se vor desfăşura în continuare.

Director,
Acad. Maya Simionescu

Anexa SC

Standardele minimale proprii Institutului de Biologie şi Patologie Celulară "Nicolae Simionescu" pentru acordarea gradelor profesionale

Ocuparea posturilor de cercetare-dezvoltare şi inovare (CDI) în cadrul Institutului de Biologie şi Patologie Celulară "Nicolae Simionescu" (IBPC-NS) se realizează prin concurs organizat pentru ocuparea unui post vacant sau prin examen de promovarea pe un gradul profesional superior celui ocupat.

În vederea participării la concursurile organizate de către IBPC-NS, pentru ocuparea poziţiilor CDI vacante, candidaţii trebuie să îndeplinească obligatoriu standardele minimale legale (conform Legii 183/2024 şi a Ordinului ministrului 6129/2016 privind statutul personalului CDI), dar şi standardele suplimentare proprii IBPC-NS stabilite şi aprobate în Consiliul Ştiinţific.

În vederea promovării, doar cercetătorii ştiinţifici CS, CSIII şi CSII, cu contract individual de muncă pe perioadă nedeterminată, care depăşesc cu minimum 50%, cel puţin două treimi din standardele minimale proprii ale IBPC-NS, pot susţine examen pentru promovarea pe gradul profesional superior în IBPC-NS. Promovarea se face prin încheierea unui act adiţional la contractul individual de muncă existent.

1. Standardele minimale proprii IBPC-NS pentru acordarea gradului profesional de CSI

Cercetătorii ştiinţifici CSII, care au contract individual de muncă pe perioadă nedeterminată, pot susţine examenul pentru promovarea într-un grad profesional superior, în IBPC-NS, cu condiţia să îndeplinească următoarele criterii:

- să îndeplinească toate cele 4 standarde minimale prevăzute la criteriile 1-4;
- să depăşească cu minimum 50% cel puţin trei dintre cele patru standarde minimale.

Promovarea se realizează prin încheierea unui act adiţional la contractul individual de muncă existent.

Criteriul 1. Articole ştiinţifice publicate după doctorat, ca autor principal

Standard minim: Candidatul trebuie să fi publicat, după obţinerea titlului de doctor, cel puţin 4 articole publicate în reviste cotate ISI, cu un AIS* cumulat de minimum 4 – în care figurează ca autor principal (primul autor, autor corespondent sau ultimul autor, după caz).

Pentru promovare (prin depăşirea cu cel puţin 50% a standardului): cel puţin 6 articole publicate în reviste cotate ISI, cu un AIS* cumulat mai mare sau egal cu 6 – în care figurează ca autor principal (primul autor, autor corespondent sau ultimul autor, după caz).

Criteriul 2. Articole ştiinţifice publicate în ultimii 5 ani, ca autor principal

Standard minim: Candidatul trebuie să fi publicat, în ultimii 5 ani, cel puţin **2 articole** în reviste cotate ISI, – fiecare articol având un AIS* de minimum 0,5– în care figurează ca autor principal (primul autor, autor corespondent sau ultimul autor, după caz).

Pentru promovare (prin depăşirea cu cel puţin 50% a standardului): Candidatul trebuie să fi publicat, în ultimii 5 ani, cel puţin **3 articole** în reviste cotate ISI, – fiecare articol având un AIS* de minimum 0,5 – în care figurează ca autor principal (primul autor, autor corespondent sau ultimul autor, după caz).

**Nota:*
- Factorul AIS (Article Influence Score), conform https://jcr.clarivate.com/ din anul publicării; în cazul articolele publicate înainte de 2007 se va utiliza valoarea AIS din 2007. Dacă clasificarea din anul publicării nu este disponibilă, va fi luată în considerare cea mai recentă clasificare disponibilă.
- Valoarea AIS pentru condiţiile preliminare obligatorii se fracţionează după formula: AIS/pi, unde pi are valoarea 1, atunci când articolul are 1, 2 sau 3 autori principali (care sunt: primul, ultimul şi autorul corespondent) sau reprezintă numărul de autori principali ai articolului atunci când numărul acestora este mai mare de 3.
- Minim 50% din articolele ştiintifice publicate trebuie să fie regăsite in Web of Science cu încadrarea la "document type": "article". În acest procent nu intră lucrările având încadrarea "document type": "review"; sau combinaţii multiple precum: „Article; Proceedings Paper", „Article; Book Chapter", etc.

Criteriul 3. Coordonare proiecte de cercetare/granturi, obţinute în perioada de după doctorat:**

Standard minim: Candidatul trebuie să fi coordonat, după obţinerea titlului de doctor, cel puţin două proiecte/granturi de cercetare**, naţionale sau internaţionale, în una dintre următoarele variante:

- două proiecte (naţionale sau internaţionale), în calitate de director de proiect sau responsabil de partener, sau
- un proiect naţional şi un proiect internaţional (în calitate de director sau responsabil naţional).

Notă: Pentru cel puţin unul dintre aceste proiecte, echipa de cercetare coordonată trebuie să includă minimum 3 membri.

Pentru promovare (prin depăşirea cu minimum 50% a standardului): Candidatul trebuie să fi coordonat, după obţinerea titlului de doctor, cel puţin trei proiecte/granturi de cercetare**, naţionale sau internaţionale, în una dintre următoarele variante:

- 3 proiecte/ granturi de cercetare, (naţionale sau internaţionale), în calitate de director sau responsabil de partener; sau

- 2 proiect naţionale şi 1 proiect internaţional (ca director sau responsabil naţional); sau
- 1 proiect naţional şi 2 proiect internaţionale (ca director sau responsabil naţional);

Notă: Pentru cel puţin unul dintre aceste proiecte, echipa de cercetare coordonată trebuie să includă minimum 3 membri.

**Nota*
- Proiectele sa fie obţinute: (1) prin competiţie naţională sau internaţională, caz în care se va preciza link-ul către pagina competiţiei sau alte documente care să demonstreze competiţia; (2) prin atribuire fără competiţie, caz în care bugetul grantului să fie echivalent cu minim 50000 euro.
- Nu se iau în considerare proiectele care nu au cheltuieli de logistică, granturi finanţate de propria instituţie sau granturi pentru participare la congrese.
- Proiectele trebuie sa fie derulate într-o instituţie cu activităţi de cercetare-dezvoltare.

Criteriul 4. Cuantificarea activităţii ştiinţifice

Standard minim: Punctaj total rezultat pe baza calculului indicatorilor din tabelul 1: **500** pct. Σ_1-2 şi **600** pct. Σ_1-18.

Pentru promovare (prin depăşirea cu minimum 50% a standardului): Punctaj total rezultat pe baza calculului indicatorilor din tabelul 1: **750** pct. Σ_1-2 şi **900** pct. Σ_1-18.

Tabel 1 Parametrii luaţi în calcul şi modul lor de cuantificare

Nr. crt.	*Parametrul*	*Mod de calcul*	*Punctaj*
1.	Articole în reviste cotate WoS, ca autor principal	conform formulei (1)	
2.	Articole în reviste cotate WoS, ca şi coautor	conform formulei (2)	
3.	Articole în reviste indexate BDI ca autor principal	(1+C_1)+(1+C_2)+... (1+C_n)	
4.	Articole în reviste indexate BDI ca şi coautor	0.7 x [(1+C_1)+(1+C_2)+... (1+c_n)]	
5.	Cărţi la edituri internaţionale de prestigiu	(100+c):n	
6.	Cărţi la alte edituri internaţionale	(40+c):n	
7.	Cărţi la Editura Academiei Române sau la edituri Universitare	(20+c):n

16.	Editor (inclusiv guest editor) la reviste cotate WoS	5 X (AIS_1+AIS_2+ ... AIS_n)	
17.	Proiecte/granturi de cercetare câştigate prin competiţie	1 punct la fiecare 10000 euro atraşi ca director de proiect sau responsabil de partener	
18.	Implicare constantă şi susţinută în activităţile ştiinţifice organizate în cadrul institutului, inclusiv participarea activă la seminarii, workshopuri şi alte manifestări ştiinţifice interne (discuţii, întrebări sau feedback oferit altor colegi în timpul acestor evenimente);	2 puncte per eveniment	

Formula (1):1 x [4+(7xAIS_1)+c1] + 1 x [4+(7xAIS_2)+c2] + ... + 1 x [4+(7XAIS_N)+C_N]
Formula (2):0.7 x [4+(7xAIS_1)+c_1] + 0.7 x [4+(7xAIS_2)+c_2] + ... + 0.7 x [4+(7XAIS_N)+C_N]AIS_1, AIS_2 ..., AIS_N este factorul AIS (Article Influence Score), conform Journal Citation Reports (publicat de Clarivate) din anul publicării. În cazul articolele publicate înainte de 2007 se va utiliza valoarea AIS din 2007. Dacă clasificarea din anul publicării nu este disponibilă, va fi luată în considerare cea mai recentă clasificare disponibilă.
c_1, c_2 ... c_n numărul de citări fără autocitări pentru articolul 1, 2..., N, preluat de pe Web of Science sau Scopus, în momentul întocmirii dosarului, cu specificarea sursei utilizate.
c - citări fără autocitări preluat de pe Web of Science sau Scopus, în momentul depunerii dosarului, cu specificarea sursei utilizate. Se consideră autocitare situaţia în care autorul evaluat citează o lucrare anterioară la care a fost autor.
N - numărul total de articole din categoria respectivă (fără rezumate/abstract, recenzii, comemorări, note, editoriale, corecturi, erate).
n - numărul de autori (editori, redactori, coordonatori pentru cărţile/capitolele editate/elaborate).

Parametrul	Punctaj total rezultat pe baza calculului indicatorilor din tabelul 1
Σ_1-2 (recunoaştere internaţională)	**Standard minim: 500 pct. Pentru promovare 750 pct.**
Σ_1-18 (performanţa totală)	**Standard minim: 600 pct. Pentru promovare 900 pct.**

2. Standardele minimale proprii IBPC-NS pentru acordarea gradului profesional de CSII

Cercetătorii ştiinţifici CS III, care au contract individual de muncă pe perioadă nedeterminată, pot susţine examenul pentru promovarea într-un grad profesional superior, în IBPC-NS, cu condiţia să îndeplinească următoarele criterii:

- să îndeplinească toate cele 3 standarde minimale prevăzute la criteriile 1-3;
- să depășească cu minimum 50% cel puțin două dintre cele trei standarde minimale.

Promovarea se realizează prin încheierea unui act adițional la contractul individual de muncă existent.

Criteriul 1. Articole științifice publicate după doctorat, ca autor principal

Standard minim: Candidatul trebuie să fi publicat, după obținerea titlului de doctor, cel puțin 2 articole științifice în reviste cotate ISI, în care să figureze ca autor principal care să îndeplinească următoarele cerințe:

- AIS* cumulat al celor două articole trebuie să fie cel puțin 2.
- Cel puțin un articol trebuie să fi fost publicat în ultimii 5 ani și să aibă un AIS* de minimum 0,4.

Pentru promovare (depășire cu minimum 50%): Candidatul trebuie să fi publicat, după obținerea titlului de doctor, ca autor principal:

- Minimum 3 articole publicate în reviste cotate ISI, cu un AIS* cumulat de cel puțin 3;
- Cel puțin 2 articole trebuie să fi fost publicate în ultimii 5 ani, fiecare cu un AIS* de minimum 0,4.

**Nota:*
- Factorul AIS (Article Influence Score), conform https://jcr.clarivate.com/ din anul publicării; în cazul articolele publicate înainte de 2007 se va utiliza valoarea AIS din 2007. Dacă clasificarea din anul publicării nu este disponibilă, va fi luată în considerare cea mai recentă clasificare disponibilă.
- Valoarea AIS pentru condițiile preliminare obligatorii se fracționează după formula: AIS/pi, unde pi are valoarea 1, atunci când articolul are 1, 2 sau 3 autori principali (care sunt: primul, ultimul si autorul corespondent) sau reprezintă numărul de autori principali ai articolului atunci când numărul acestora este mai mare de 3.
- Minim 50% din articolele științifice publicate trebuie să fie regăsite in Web of Science cu încadrarea la "document type": "article". In acest procent nu intră lucrările având încadrarea "document type": "review"; sau combinatii multiple precum: „Article; Proceedings Paper", „Article; Book Chapter", etc.

Criteriul 2. Coordonare proiecte de cercetare/granturi, obținute în perioada de după doctorat**:

Standard minim: După obținerea titlului de doctor, candidatul trebuie să fi coordonat cel puțin un proiect sau grant de cercetare, național sau internațional, în calitate de director de proiect sau responsabil de partener.

Pentru promovare (prin depășirea cu minimum 50% a standardului): Candidatul trebuie să fi coordonat minimum două proiecte sau granturi de cercetare (naționale sau internaționale, în calitate de director sau responsabil de partener).

Notă: Pentru cel puțin unul dintre proiectele coordonate, echipa de cercetare trebuie să includă minimum 3 membri.

**Nota*

- Proiectele sa fie obținute: (1) prin competiție națională sau internațională, caz în care se va preciza link-ul către pagina competiției sau alte documente care să demonstreze competiția; (2) prin atribuire fără competiție, caz în care bugetul grantului să fie echivalent cu minim 50000 euro.

- Nu se iau în considerare proiectele care nu au cheltuieli de logistică, granturi finanțate de propria instituție sau granturi pentru participare la congrese.

- Proiectele trebuie sa fie derulate într-o instituție cu activități de cercetare-dezvoltare.

Criteriul 3. Cuantificarea activității științifice

Standard minim: Punctaj total rezultat pe baza calculului indicatorilor din tabelul 1: **300** pct. Σ_1-2 și **450** pct. Σ_1-18.

Pentru promovare (prin depășirea cu minimum 50% a standardului): Punctaj total rezultat pe baza calculului indicatorilor din tabelul 1: **450** pct. Σ_1-2 și **675** pct. Σ_1-18.

Tabel 1 Parametrii luați în calcul și modul lor de cuantificare

3. Standardele minimale proprii IBPC-NS pentru acordarea gradului profesional de CSIII

Cercetătorii ştiinţifici CS, care au contract individual de muncă pe perioadă nedeterminată, pot susţine examenul pentru promovarea într-un grad profesional superior, în IBPC-NS, cu condiţia să îndeplinească următoarele criterii:

- să îndeplinească toate cele 3 standarde minimale prevăzute la criteriile 1-3;
- să depăşească cu minimum 50% cel puţin două dintre cele trei standarde minimale.

Criteriul 1. Articole ştiinţifice publicate

Standard minim: Candidatul trebuie să fi publicat, cel puţin 5 articole ştiinţifice în reviste cotate ISI, în calitate de autor principal sau coautor.

Pentru promovare (prin depăşirea cu minimum 50% a standardului): Este necesară publicarea a cel puţin 8 articole ISI, în calitate de autor principal sau coautor.

Criteriul 2. Articole ştiinţifice publicate cu AIS cumulat minim 2

Standard minim: Candidatul trebuie să fi publicat **cel puţin 2 articole** în reviste cotate ISI, cu un *AIS** cumulat de minimum 2.

Pentru promovare (prin depăşirea standardului cu cel puţin 50%): Este necesară publicarea a **cel puţin 3 articole** în reviste cotate ISI, cu un *AIS** cumulat de minimum 3.

**Nota:*
- Factorul AIS (Article Influence Score), conform https://jcr.clarivate.com/ din anul publicării; în cazul articolele publicate înainte de 2007 se va utiliza valoarea AIS din 2007. Dacă clasificarea din anul publicării nu este disponibilă, va fi luată în considerare cea mai recentă clasificare disponibilă.
- Valoarea AIS pentru condiţiile preliminare obligatorii se fracţionează după formula: AIS/pi, unde pi are valoarea 1, atunci când articolul are 1, 2 sau 3 autori principali (care sunt: primul, ultimul şi autorul corespondent) sau reprezintă numărul de autori principali ai articolului atunci când numărul acestora este mai mare de 3.
- Minim 50% din articolele ştiintifice publicate trebuie să fie regăsite in Web of Science cu încadrarea la "document type": "article". În acest procent nu intră lucrările având încadrarea "document type": "review"; sau combinaţii multiple precum: „Article; Proceedings Paper", „Article; Book Chapter", etc.

Criteriul 3. Cuantificare performanţă ştiinţifică

Standard minim: Punctaj total rezultat pe baza calculului indicatorilor din tabelul 1: **100** pct. Σ_1-2 şi **150** pct. Σ_1-17.

Pentru promovare (prin depăşirea cu minimum 50% a standardului): Punctaj total rezultat pe baza calculului indicatorilor din tabelul 1: **150** pct. Σ_1-2 şi **225** pct. Σ_1-17.

Tabel 1 Parametrii luaţi în calcul şi modul lor de cuantificare

Nr. crt.	*Parametrul*	*Mod de calcul*	*Punctaj*
1.	Articole în reviste cotate WoS, ca autor principal	conform formulei (1)	
2.	Articole în reviste cotate WoS, ca şi coautor	conform formulei (2)	

3.	Articole în reviste indexate BDI ca autor principal	(1+C_1)+(1+C_2)+... (1+C_n)	
4.	Articole în reviste indexate BDI ca şi coautor	0.7 x [(1+C_1)+(1+C_2)+... (1+c_n)]	
5.	Cărţi la edituri internaţionale de prestigiu	(100+c):n	
6.	Cărţi la alte edituri internaţionale	(40+c):n	
7.	Cărţi la Editura Academiei Române sau la edituri Universitare	(20+c):n	
8.	Cărţi la alte edituri din ţară	(10+c): n	
9.	Capitole în volume la edituri internaţionale de prestigiu	(50+c):n	
10.	Capitole în volume la alte edituri internaţionale	(20+c): n	
11.	Capitole în volume la editura Academiei sau la edituri Universitare	(10+c): n	
12.	Capitole în cărţi/volume la edituri naţionale	(5+c):n	
13.	Editor/redactor/coordonator cărţi la edituri internaţionale de prestigiu	(50+c):n	
14.	Editor/redactor/coordonator cărţi la alte edituri internaţionale	(30+c):n	
15.	Editor/redactor/coordonator cărţi la edituri naţionale	(20+c): n	
16.	Editor (inclusiv guest editor) la reviste cotate WoS	5 X (AIS_1+AIS_2+ ... AIS_n)	
17.	Implicare constantă şi susţinută în activităţile ştiinţifice organizate în cadrul institutului, inclusiv participarea activă la seminarii, workshopuri şi alte manifestări ştiinţifice interne (discuţii, întrebări sau feedback oferit altor colegi în timpul acestor evenimente);	2 puncte per eveniment	

Formula (1):1 x [4+(7xAIS_1)+c1] + 1 x [4+(7xAIS_2)+c2] + ... + 1 x [4+(7XAIS_N)+C_N]
Formula (2):0.7 x [4+(7xAIS_1)+c_1] + 0.7 x [4+(7xAIS_2)+c_2] + ... + 0.7 x [4+(7XAIS_N)+C_N]AIS_1, AIS_2 ..., AIS_N este factorul AIS (Article Influence Score), conform Journal Citation Reports (publicat de Clarivate) din anul publicării. În cazul articolele publicate înainte de 2007 se va utiliza valoarea AIS din 2007. Dacă clasificarea din anul publicării nu este disponibilă, va fi luată în considerare cea mai recentă clasificare disponibilă.
c_1, c_2 ... c_n numărul de citări fără autocitări pentru articolul 1, 2..., N, preluat de pe Web of Science sau Scopus, în momentul întocmirii dosarului, cu specificarea sursei utilizate.
c - citări fără autocitări preluat de pe Web of Science sau Scopus, în momentul depunerii dosarului, cu specificarea sursei utilizate. Se consideră autocitare situaţia în care autorul evaluat citează o lucrare anterioară la care a fost autor.
N - numărul total de articole din categoria respectivă (fără rezumate/abstract, recenzii, comemorări, note, editoriale, corecturi, erate).
n - numărul de autori (editori, redactori, coordonatori pentru cărţile/capitolele editate/elaborate).

Parametrul	Punctaj total rezultat pe baza calculului indicatorilor din tabelul 1/promovare
Σ_1-2 (recunoaștere internațională)	**Standard minim: 100 pct. Pentru promovare 150 pct.**
Σ_1-17 (performanța totală)	**Standard minim: 150 pct. Pentru promovare 225 pct.**

4. **Standardele minimale pentru acordarea gradului profesional de CS**

Criteriile minime pentru participarea la concursul de CS:

1. Absolvent cu **examen de licență sau de diplomă** al studiilor în învățământul universitar de lungă durată sau absolvent cu diplomă de master în specialitate sau domenii conexe (doar pentru concurs);
2. Calitatea de doctorand sau doctor în specialitatea disciplinelor postului sau înrudită cu aceasta (doar pentru concurs);
3. Minim două **scrisori de recomandare** de la supervizori și/sau profesori de curs (doar pentru concurs).
4. Un articol științific publicat într-un jurnal cotat ISI în calitate de co-autor în poziția 2 sau 3 sau într-un jurnal cotat BDI ca autor principal (doar pentru concurs).

5. **Standardele minimale pentru acordarea gradelor profesionale de ACS**

Criteriile minime pentru participarea la concursul de ACS:

1. Absolvent cu **examen de licență sau de diplomă** al studiilor în învățământul universitar de lungă durată sau absolvent cu diplomă de master în specialitate sau domenii conexe (doar pentru concurs);
2. Minim două **scrisori de recomandare** de la supervizori și/sau profesori de curs (doar pentru concurs)

Aprobat în ședința Consiliului Științific al IBPC-NS din data_07.08.2025_____.

DIRECTOR ICBP N. Simionescu **26.06.2025**
Acad Maya SIMIONESCU

Documente utilizate pentru documentarea și elaborarea prezentului regulament:
Ordinele ministrului 6129/2016 și 3019/2025 privind aprobarea standardelor minimale (pentru acordarea gradului profesional de cercetător științific gradul II și gradul I); HG 1568/2024, HG 1569/2024, Normele metodologice aprobate de către Biroul Prezidiului Academiei Române, privind organizarea examenului de promovare pentru obținerea gradului profesional de către personalul CDI/iulie 2025; Metodologia de verificare și evaluare a dosarelor ce conțin documentele aferente concursului, respectiv examenului, pentru acordarea gradului profesional de CSII și CSI; Legea 183/2024 privind statutul personalului CDI;

Anexe utile întocmirii dosarului pentru înscrierea la examenul de promovare (candidat):

Anexa DP: Documente necesare înscrierii (dosarului) pentru examenul de promovare și Lista cuprinzând documentele dosarului de examen pentru obținerea gradelor profesionale de cercetare-dezvoltare de CSII și CSI (*conform **ANEXA 1 la metodologie**, Normele metodologice privind organizarea examenului de promovare pentru obținerea gradelor profesionale de CDI din institutele AR);*

Anexa L: Pașii procedurali pentru realizarea linkurilor la documentele justificative/suport din opis *(conform **ANEXA 3 la metodologie,** Normele metodologice privind organizarea examenului de promovare pentru obținerea gradelor profesionale de CDI din institutele AR);*

Anexa 1P: Cerere de înscriere la examen-model (*conform **ANEXA 5 la listă,** Normele metodologice privind organizarea examenului de promovare pentru obținerea gradelor profesionale de CDI din institutele AR*);

Anexa 2P: Copertă dosar de examen-model *(conform **ANEXA 1 la listă**, Normele metodologice privind organizarea examenului de promovare pentru obținerea gradelor profesionale de CDI din institutele AR);*

Anexa 3P: Declarație pe proprie răspundere (candidat)-model (*conform **ANEXA 3 la listă,** Normele metodologice privind organizarea examenului de promovare pentru obținerea gradelor profesionale de CDI din institutele AR)*;

Anexa 4P: Declarație de consimțământ privind prelucrarea datelor cu caracter personal, conform Regulamentului (UE) 2016/679-model *(conform **ANEXA 4 la listă**, Normele metodologice privind organizarea examenului de promovare pentru obținerea gradelor profesionale de CDI)*;

Anexa 5P: Fișa de verificare a îndeplinirii standardelor specifice postului/gradului profesional.

Anexe utile procesului de evaluare a dosarelor (comisii, IBPC-NS):

Anexa 1E: Declarație (evaluator)-model *(conform **ANEXA 2 la metodologie**, Normele metodologice privind organizarea examenului de promovare pentru obținerea gradelor profesionale de CDI din institutele AR);*

Anexa 2E: Referat de apreciere (membru comisie)-model *(conform **ANEXA 3 la listă**, Normele metodologice privind organizarea examenului de promovare pentru obținerea gradelor profesionale de CDI din institutele AR*).

Documente necesare înscrierii la examenul de promovare

a. cererea de înscriere la examen, la care se anexează o declaraţie pe propria răspundere privind veridicitatea informaţiilor prezentate în dosar, completate şi semnate în original de către candidat (Anexa 1P şi Anexa 3P);

a. curriculum-ul vitae după model EUROPASS semnat de către candidat (Anexa 3), obligatoriu să conţină: i. studiile efectuate şi diplomele obţinute; ii. experienţa profesională şi locurile de muncă relevante ocupate anterior; iii. proiectele de cercetare, dezvoltare şi inovare pe care le-a condus ca director de proiect şi granturile obţinute, dacă este cazul, indicându-se pentru fiecare sursa de finanţare, volumul finanţării şi principalele publicaţii sau brevete de invenţie rezultate; iv. premiile sau alte elemente de recunoaştere a contribuţiilor ştiinţifice; v. descrierea narativă a celor mai importante 3 realizări de la ultima promovare- maximum 3 pagini;

b. lista publicaţiilor, lucrărilor, articolelor/studiilor, brevetelor de invenţie selectate de candidat în funcţie de relevanţa pentru activităţile de cercetare ştiinţifică proprii, semnate în original de către candidat (Anexa 4). Lista trebuie să conţină obligatoriu: i. lista a cel mult 10 publicaţii ştiinţifice, cele mai relevante, precum: cărţi de autor, articole/studii/capitole, volume editate, lucrări; ii. lista brevetelor de invenţie şi a altor titluri de proprietate industrială; iii. lista cărţilor de autor şi a volumelor editate şi publicate; iv. lista articolelor/studiilor in extenso, publicate în reviste din fluxul ştiinţific internaţional principal; v. lista altor lucrări şi contribuţii ştiinţifice;

c. fişa de verificare a îndeplinirii standardelor proprii ale organizaţiei de cercetare, completată şi semnată de către candidat (Anexa 5P);

d. copia actului de identitate sau orice alt document care atestă identitatea, potrivit legii, după caz, certificată de către candidat conform cu originalul, numele în clar şi semnătura;

e. copia certificatului de căsătorie sau dovada schimbării numelui, după caz, certificată de către candidat conform cu originalul, numele în clar şi semnătura;

f. certificatul medical care să ateste starea de sănătate corespunzătoare, eliberată de către medicul de familie al candidatului sau de către unităţile sanitare abilitate cu cel mult 3 luni anterior derulării examenului;

g. declaraţia de consimţământ pentru prelucrarea datelor cu caracter personal semnată (Anexa 4P);

h. certificatul de cazier judiciar.

i. copia diplomei de doctorat, în situaţia în care diploma nu a fost eliberată de o instituţie de învăţământ superior din România se depune o copie a atestatului de recunoaştere sau de echivalare a acesteia, certificată de către candidat conform cu originalul, numele în clar şi semnătura;

j. declaraţia pe propria răspundere în care se menţionează că, în ultimii 3 ani anteriori înscrierii la examenul de promovare, candidatul nu a fost sancţionat pentru săvârşirea unei abateri grave de la buna conduită în activitatea CDI prevăzute la art. 52 alin. (8) din Legea

nr. 183/2024, completată şi semnată de către candidat (Anexa 3P).

Documentele se depun în dosar format fizic, cât şi în format electronic (fiecare document din dosarul fizic va fi scanat conform opis-ului şi salvat pe un memory stick) la sediul IBPC-NS, dar şi la adresa de e-mail indicată în anunţ.

Dosarul de examen pentru ocuparea postului de CSII sau CSI se constituie din două părţi, astfel:
a) dosarul administrativ cuprinde documentele menţionate la punctele **a-j** şi documentele emise pe durata desfăşurării examenului. Toate documentele se înregistrează, se atribuie un link fiecărui document, conform paşilor procedurali prevăzuţi în Anexa L, se opisează şi se numerotează, apoi vor fi scanate în ordinea menţionată în "Lista cuprinzând documentele dosarului de concurs, respectiv examen", prevăzută în Anexa DP;
b) mapa cu lucrări ştiinţifice - lucrările se scanează în format PDF, se atribuie un link fiecărui document, apoi se numerotează şi se opisează.

LISTA
cuprinzând documentele dosarului de examen pentru obţinerea gradele profesionale de cercetare-dezvoltare de CSII şi CSI

Documentele de mai jos vor fi îndosariate în format electronic, de tip PDF, separate, ataşate în ordinea prevăzută de opis. Documentele vor fi numerotate conform opisului.
Dosarul de examen se depune numai în formă completă, conţinând toate documentele aferente postului pentru care candidatul aplică, în ordinea în care figurează mai jos. Introducerea de informaţii false sau documente neconforme în dosarul de examen se sancţionează conform normelor legale.

Formularul-tip al copertei se completează de către candidat potrivit Anexei 2P.

Fiecare dosar de examen pentru acordarea gradelor profesionale de CSII şi CSI va cuprinde următoarele documente:
A. Dosar administrativ
1. Adresa de înaintare pentru fiecare dosar din partea conducerii institutelor de cercetare/centrelor de cercetare/filialelor Academiei Române către Academia Română, care va conţine: numele şi prenumele candidatului, gradul ştiinţific actual, organizaţia din care face parte sau care organizează examenul, gradul ştiinţific pentru care este înscris la examen, domeniul postului vizat - comisia de specialitate - domeniul fundamental şi domeniul arondat, numărul de file al dosarului, numărul de înregistrare şi datele de contact ale persoanei/instituţiei emitente pentru detalii/informări şi transmiterea rezultatului evaluării.
2. Opis cu documentele din dosar cu indicarea paginii unde se găseşte fiecare document, cu link-urile aferente potrivit Anexei L.

3. Referat de prezentare a examenului aprobat de conducerea instituţiei organizatoare:
- se prezintă etapele examenului - de la publicarea anunţului de examen, data anunţului, unde a fost publicat, decizia de numire a comisiei de examen şi a comisiei de contestaţii, rezultatele evaluării, până la validarea rezultatelor în consiliul ştiinţific;
- se va menţiona domeniul, Secţia ştiinţifică din cadrul Academiei Române care va evalua dosarul candidatului;
- se va face trimitere la pagina de internet proprie a regulamentului de examen pentru posturile/gradele de CSI şi CSII, aprobată de conducerea unităţii organizatoare
4. Extras din procesul-verbal al şedinţei consiliului ştiinţific - data, membrii consiliului şi membrii prezenţi, aprobarea rezultatelor examenului de promovare
5. Extras din şedinţa Consiliului ştiinţific privind aprobarea organizării examenului de promovare pentru institutele de cercetare/centrele de cercetare din cadrul Academiei Române. În cazul Filialelor Academiei Române, aprobarea Preşedintelui Filialei/Biroului de conducere al Filialei/ ca urmare a avizării Consiliului ştiinţific privind propunerea institutelor din subordine de organizare a examenelor de promovare.
6. Raportul comisiei de examen, elaborat cu respectarea prevederilor legale, ce cuprinde toate etapele de desfăşurare a examenului de promovare.
7. Referatul de apreciere a membrilor comisiei de examen de promovare pentru obţinerea gradului profesional de CSII sau CSI, prevăzut la Anexa 2E la prezenta listă, şi declaraţia, pe propria răspundere prevăzută la Anexa 1E. Ambele documente trebuie să fie asumate de cei în cauză, semnate, datate şi înregistrate la secretariatul IBPC-NS.
8. Decizia de numire a comisiilor de examen şi de contestaţii, menţionându-se funcţia, gradul universitar sau de cercetare, numele şi prenumele, precum şi locul de muncă pentru fiecare membru al comisiei.
9. Cererea de înscriere la examen, înregistrată, semnată şi datată de candidat, aprobată de conducătorul organizaţiei de cercetare şi inovare şi avizată de compartimentul juridic al acesteia, după caz, prevăzută la Anexa 1P.
10. Fişa de verificare a îndeplinirii standardelor specifice postului/gradului profesional pentru care candidează, care este completată şi asumată de candidat şi avizată de organizaţia de cercetare în domeniul solicitat de candidat conform prevederilor legale. Se vor lua în considerare numai publicaţiile apărute, adică cele care au volum, număr, pagini şi/sau un identificator digital, conform standardelor internaţionale. Fişa va fi completată într-un format care să faciliteze verificarea informaţiilor; în coloane paralele vor fi introduse valorile standardelor minimale impuse de actele normative şi valorile finale obţinute de către candidat pentru fiecare standard (Anexa 5P).
11. Propunerea de dezvoltare a carierei ştiinţifice din punctul de vedere al activităţilor de cercetare ştiinţifică, formată din maximum 5 pagini.
12. Declaraţia de asumare a răspunderii, printr-un înscris olograf semnat de candidat, cu toate datele de identificare ale acestuia, în care afirmă că datele din dosar se referă la propriile activităţi şi realizări, în caz contrar candidatul suportând consecinţele declaraţiilor în fals, în conformitate cu legislaţia în vigoare. De asemenea, candidatul îşi asumă răspunderea cu privire la

asigurarea originalităţii conţinutului mapei ştiinţifice, precum şi a respectării standardelor de calitate şi de etică profesională potrivit Anexei 3P.

13. Declaraţie de consimţământ privind prelucrarea datelor cu caracter personal, conform Regulamentului (UE) 2016/679, prevăzută la Anexa 4P.

14. Curriculum Vitae al candidatului - model Europass, în format electronic, de tip PDF, cu datele de contact, datat şi semnat de acesta.

15. Informaţii despre premii sau alte elemente de recunoaştere a contribuţiilor ştiinţifice ale candidatului.

16. Actele doveditoare ale studiilor - copia diplomei de licenţă sau echivalentă/masterat/doctorat, după caz, conformă cu originalul. În situaţia în care candidatul declarat câştigător nu deţine o diplomă eliberată de o instituţie de învăţământ superior din România, acesta trebuie să depună o copie conformă cu originalul a atestatului de recunoaştere sau de echivalare a acesteia înainte de încadrarea pe post şi semnarea contractului individual de muncă, sub sancţiunea neemiterii actului administrativ de încadrare pe post.

17. Actele doveditoare ale identităţii.

a) copie după certificatul de naştere;

b) în cazul în care candidatul şi-a schimbat numele, copie după documentul care atestă schimbarea numelui - certificat de căsătorie sau dovada schimbării numelui;

c) copia actului de identitate sau orice alt document care atestă identitatea, potrivit legii.

18. Certificat de cazier judiciar.

19. Actul doveditor al stării de sănătate eliberat de către medicul de familie al candidatului.

20. Copie a anunţului privind examenul de promovare, care a fost afişat la sediul instituţiei şi pe site-ul instituţiei organizatoare.

B. Mapă cu lucrări ştiinţifice

Lista publicaţiilor ştiinţifice pe categorii, lucrărilor, articolelor/studiilor, brevetelor considerate de candidat a fi relevante pentru domeniul postului pentru care candidează, pentru activităţile de cercetare ştiinţifică proprii, proiecte de cercetare-dezvoltare pe bază de contract/grant, altele (inclusiv citările).

Lista este structurată astfel:

a) teza sau tezele de doctorat;

b) lista celor mai relevante 10 publicaţii ştiinţifice (cărţi de autor, articole/studii/capitole, volume editate);

c) lista brevetelor de invenţie şi a altor titluri de proprietate industrială;

d) lista cărţilor de autor şi a volumelor editate şi publicate;

e) lista articolelor/studiilor in extenso, publicate în reviste din fluxul ştiinţific internaţional principal;

f) lista altor lucrări şi contribuţii ştiinţifice sau, după caz, din domeniul creaţiei artistice sau apărării naţionale;

g) proiecte de cercetare-dezvoltare-inovare pe bază de contract/grant;

h) alte lucrări.

NOTĂ:
Toate documentele din dosar se înregistrează la secretariatul unităţii organizatoare a examenului de promovare, iar pe cele care sunt în copie se menţionează "conform cu originalul", se semnează şi se datează.

Anexa L

Paşii procedurali pentru realizarea linkurilor la documentele justificative/suport din opis:

A. Copierea iniţială a opisului şi a documentelor pe suport USB

B. Pentru atribuirea unui link fiecărui document din opis se va proceda astfel:

1. Se selectează textul pe care se doreşte introducerea linkului.

2. În meniul Insert -> faceţi click pe iconiţa Link

[sau apăsaţi simultan tastele Ctrl şi K (Ctrl + K)].
3. Din fereastra Insert Hyperlink se selectează cu click doc. căruia se doreşte să i se facă legătură.
4. Se apasă OK.
5. După introducerea linkului se verifică legătura apăsând tasta Ctrl şi făcând simultan click(Ctrl+Click).

După salvarea documentului ca PDF, linkurile ar trebui să fie funcţionale.

După definitivarea linkurilor se verifică funcţionalitatea acestora.

Anexa 4P

DECLARAȚIE DE CONSIMȚĂMÂNT
privind prelucrarea datelor cu caracter personal, conform Regulamentului (UE) 2016/679

Subsemnatul(a), ..., domiciliat(ă) în ....., născut(ă) la data de ..... în localitatea ....., județul ....., posesor/posesoare al/a C.I. seria ... nr. ....., emisă la data de ..... de către ....., având CNP ....., în calitate de participant(ă) la examenul de promovare din ..... în ....., organizat de către Institutul de Biologie și Patologie Celulară „Nicolae Simionescu", declar prin prezenta că sunt de acord cu utilizarea și prelucrarea datelor mele cu caracter personal de către personalul desemnat din minister, inclusiv cu comunicarea lor, dacă va fi necesar, către alte entități (Comisia Națională de Atestare a Titlurilor, Diplomelor și Certificatelor Universitare, Colegiul Consultativ pentru Cercetare, Dezvoltare și Inovare etc.).

Am fost informat(ă) cu privire la prevederile Regulamentului (UE) 2016/679 privind protecția persoanelor fizice în ceea ce privește prelucrarea datelor cu caracter personal și privind libera circulație a acestor date și de abrogare a Directivei 95/46/CE (Regulamentul general privind protecția datelor) adoptat de Parlamentul European și Consiliul Uniunii Europene, respectiv:

— dreptul de acces conform căruia persoana are dreptul de a obține o confirmare din partea Autorității Naționale pentru Cercetare (*ANC*) că prelucrează sau nu prelucrează datele cu caracter personal și, în caz afirmativ, de a obține acces la datele respective și la informații privind modalitatea în care sunt prelucrate;

— dreptul la portabilitatea datelor se referă la dreptul de a primi datele personale într-un format structurat, utilizat în mod curent, și la dreptul ca aceste date să fie transmise direct altui operator, dacă acest lucru este fezabil din punct de vedere tehnic;

— dreptul la opoziție vizează dreptul persoanei de a se opune prelucrării datelor personale;

— dreptul la rectificare se referă la corectarea, fără întârzieri nejustificate, a datelor cu caracter personal inexacte;

— dreptul la ștergerea datelor („dreptul de a fi uitat") înseamnă dreptul persoanei de a solicita să îi fie șterse datele cu caracter personal, fără întârzieri nejustificate, în cazul în care apare unul din următoarele motive: acestea nu mai sunt necesare pentru îndeplinirea scopurilor pentru care au fost colectate sau prelucrate; persoana își retrage consimțământul și nu există niciun alt temei juridic pentru prelucrare;

— dreptul la restricționarea prelucrării poate fi exercitat în cazul în care persoana contestă exactitatea datelor, pe o perioadă care permite instituției verificarea corectitudinii acestora; prelucrarea este ilegală, iar persoana se opune ștergerii datelor cu caracter personal, solicitând în schimb restricționarea.

Mi s-a adus la cunoștință despre faptul că refuzul meu de a furniza datele cu caracter personal necesare și solicitate către ANC determină imposibilitatea stabilirii raporturilor cu privire la promovare și nu este imputabil instituției mai sus menționate.

Dacă datele cu caracter personal furnizate sunt incorecte sau vor suferi modificări (schimbare de domiciliu, statut civil, adresă de e-mail etc.) mă oblig să informez în scris, în timp util, ANC.

Totodată am fost informat(ă) cu privire la faptul că aceste date vor fi tratate confidențial, în conformitate cu prevederile Regulamentului (UE) 2016/679 al Parlamentului European și al Consiliului din data de 27 aprilie 2016 privind protecția persoanelor fizice în ceea ce privește prelucrarea datelor cu caracter personal.

REGULAMENT

privind organizarea concursului pentru ocuparea posturilor vacante ale personalului de cercetare în cadrul Institutului de Biologie și Patologie Celulară "Nicolae Simionescu" al Academiei Române

-Ediția I, Revizia 1-

Capitolul I. Dispoziții generale

Articolul 1. Prezentul Regulamentul stabilește metodologia de ocupare a posturilor vacante de cercetare, diferențiate pe grade profesionale, pentru personalul implicat în activități de cercetare-dezvoltare și inovare (CDI), în cadrul Institutului de Biologie și Patologie Celulară "Nicolae Simionescu" (IBPC-NS) al Academiei Române.

Articolul 2. Ocuparea pozițiilor vacante se realizează prin concurs organizat în conformitate cu prevederile Legii 53/2003 privind Codul Muncii, Legii 183/2024 privind Statutul personalului de CDI, Ordinului Ministerului Educației Naționale și Cercetării științifice nr. 6129/20.12.2016, Normelor metodologice privind organizarea concursurilor pentru ocuparea posturilor vacante ale personalului CDI emise de către Academia Română la data de 15 iulie 2025 și în conformitate cu prezentul regulament aprobat la nivelul IBPC-NS, avizat de Secția de Științe Biologice și publicat pe site-ul institutului.

Articolul 3. Regulamentul se aplică tuturor persoanelor care doresc să ocupe în IBPC-NS, pe durată determinată sau nedeterminată, una din următoarele funcții și grade profesionale de cercetare-dezvoltare, definite conform Legii 183/2024 și păstrând echivalența cu gradele profesionale prevăzute în Carta Europeană a Cercetătorilor, după cum urmează:

(i) cercetător științific gradul I (CSI), echivalent al cercetătorului senior principal R4, deținând titlul de doctor;
(ii) cercetător științific gradul II (CSII), echivalent al cercetătorului senior consacrat R3, deținând titlul de doctor;
(iii) cercetător științific gradul III (CSIII), echivalent al cercetătorului recunoscut R2, deținând titlul de doctor;
(iv) cercetător științific (CS), echivalent al cercetătorului debutant R1, deținând titlul de doctor sau având calitatea de student doctorand;
(v) asistent de cercetare științifică (ACS), echivalent al asistentului în activitatea de cercetare științifică, licențiat.

Articolul 4. Încadrarea pe posturi a personalului CDI se realizează prin concurs, organizat pe baza următoarelor principii:

a. principiul transparenţei, competenţei, egalităţii de gen, nediscriminării și accesul egal și echitabil la ocuparea posturilor vacante;
b. principiul asigurării calităţii și pregătirii profesionale a personalului de cercetare;
c. informarea corectă și completă privind organizarea și desfăşurarea concursurilor;
d. transparenţa cu privire la informaţiile administrative, financiare și de evaluare a posturilor de cercetare conform legislaţiei în vigoare.

Articolul 5.

(1) Angajarea pe posturile de cercetare vacante cu contract individual de muncă, pe perioadă nedeterminată sau determinată, este posibilă numai pentru candidatul declarat câştigător în urma concursului organizat.

(2) Angajarea pentru participarea la proiecte de cercetare, proiecte în domeniul educaţiei şi formării profesionale sau în orice alte tipuri de proiecte, indiferent de sursa de finanţare, se poate face pe perioadă determinată, cel mult egală cu durata derulării proiectului respectiv, fără parcurgerea altor formalităţi prealabile şi/sau procese de selecţie, pentru personalul nominalizat în listele de personal, corespunzător gradului deținut, ca membri în echipa proiectului, precum şi pentru personalul organizaţiei de cercetare. În cazul personalului din IBPC-NS, angajarea în cadrul unui proiect se realizează în baza deciziei Directorului, prin încheierea unui contract individual de muncă. Salariul este acordat în limita fondurilor disponibile, conform prevederilor din contractul de finanţare/regulilor finanţatorului. IBPC-NS poate refuza încheierea contractului individual de muncă, după caz, cu persoane din afara instituției care au fost nominalizate, fără a avea acordul prealabil al organizaţiei de cercetare, în listele de personal, ca membri în echipa unui proiect de cercetare, în echipa unui proiect în domeniul educaţiei şi formării profesionale sau în echipa oricărui alt tip de proiecte.

(3) La concursul pentru un post de cercetare vacant pot participa toate persoanele care nu deţin gradul profesional de cercetare-dezvoltare corespunzător postului pentru care candidează şi îndeplinesc standardele proprii stabilite de IBPC-NS. De asemenea, pot participa toate persoanele care deţin gradul profesional de cercetare-dezvoltare corespunzător postului pentru care candidează şi îndeplinesc standardele suplimentare specifice IBPC-NS, fie că sunt sau nu sunt deja încadrate în sistemul naţional CD, fără nicio discriminare, în condiţiile legii.

Ocuparea posturilor de cercetare, prin concurs, de către personalul de cercetare, dezvoltare şi inovare, denumit în continuare personal CDI este de competența IBPC-NS cu respectarea prezentelor norme metodologice, precum şi a principiilor generale şi a condiţiilor prevăzute de Carta europeană a cercetătorilor.

Capitolul II. Condiții minime de pregătire

Articolul 6. IBPC-NS organizează concurs pentru ocuparea unuia sau mai multor posturi de CDI numai dacă acestea sunt vacante și în baza unei note de fundamentare în care se propune scoaterea la concurs a postului.

Articolul 7. Se pot înscrie la concurs numai absolvenţii unităţilor de învăţământ superior acreditate, care au studii superioare de lungă durată, absolvite cu diplomă de licenţă sau echivalentă, ori studii superioare echivalente (studii universitare de licență și studii de masterat potrivit Legii 288/2004) și care îndeplinesc prevederile Legii nr. 183/2024 privind condiţiile necesare înscrierii, alin. (10-11), standardele minimale specifice fiecărui domeniu ştiinţific, alin. (1), dar și standardele suplimentare stabilite și aprobate în cadrul IBPC-NS al Academiei Române (conform Anexei SC.C)

Articolul 8. Pot participa la concurs numai persoanele care îndeplinesc urmatoarele condiții generale:

a. au cetațenie română, cetățenie a altor state membre ale Uniunii Europene sau a statelor aparținând Spațiului Economic European și domiciliul/rezidență în România;
b. au vârsta minima reglementată de prevederile legale;
c. au capacitate deplină de exercițiu;
d. au o stare de sănătate corespunzătoare postului pentru candidează, atestată pe baza adeverinței medicale eliberată de medicul de familie sau de unitățile sanitare abilitate;
e. îndeplinesc condițiile specifice postului scos la concurs;
f. nu au fost condamnați definitiv pentru săvârșirea unei infrcțiuni contra umanității, contra statului ori contra autorității.

Articol 9. Conform Legii 183/2024 privind Statutul personalului CDI (pentru gradele profesionale ACS, CS și CSIII) și a Ordinului Ministerului Educatiei Nationale și Cercetarii științifice nr. 6129/20.12.2016 (pentru gradele profesionale CSII și CSI), sunt stabilite standarde minimale obligtorii pe care trebuie să le îndeplinească persoanele care participă la concurs pentru obținerea unui post CDI.

(1) Pentru gradul profesonal ACS, standardele minimale obligatorii sunt următoarele:
a. să fie absolvent cu diplomă de licență sau diplomă de studii universitare de lungă durată, ori absolvent cu diplomă de master în specialitate sau într-un domeniu conex;
b. minim doua scrisori de recomandare de la supervizori și/sau profesori de curs.

(2) Pentru gradul profesional CS, standardele minimale obligatorii sunt următoarele:
a. să îndeplinească condițiile de obținere a gradului de ACS;
b. să fie înscris la școala doctorală sau să dețină titlul de doctor în specialitate sau domenii conexe.

(3) Pentru gradul profesional CSIII, standardele minimale obligatorii sunt următoarele:
a. să dețină titlul de doctor în specialitate sau domenii conexe;

b. cel puțin cinci articole publicate în reviste indexate în baze de date internaționale (se exclude Google Scholar);
c. cel puțin o lucrare comunicată la o conferință internațională.

(4) Pentru gradele profesionale CSII și CSI, standardele minimale obligatorii sunt următoarele:
a. să dețină titlul de doctor în specialitate sau domenii conexe;
b. standardele minimale aprobate prin ordin al ministrului educației și cercetării;
c. să dețină atestatul de abilitare (pentru obținerea gradului de CSI).

Articolul 10. Criteriile în baza cărora sunt elaborate standardele minimale pentru ocuparea funcțiilor și gradelor profesionale ale personalului CDI din IBPC-NS sunt următoarele:
a. rezultatele activității de cercetare și/sau inovare;
b. impactul activității de cercetare și/sau inovare;
c. capacitatea de a atrage fonduri de cercetare sau de a colabora cu organizații publice și/sau private de cercetare;
d. prestigiul profesional;
e. capacitatea organizatorică;
f. capacitatea de cooperare internațională.

Capitolul III. Cadrul general de organizare a concursului

Articolul 11.
(1) IBPC-NS organizează concurs pentru ocuparea unuia sau mai multor posturi de CDI numai dacă acestea sunt vacante și în baza unei note de fundamentare în care se propune scoaterea la concurs a postului.
(2) Un post se consideră vacant dacă este prevăzut astfel în statul de funcţii întocmit anual sau dacă este vacantat pe parcursul anului.
(3) Postul se vacantează prin una dintre următoarele modalităţi:
a. încetarea contractului individual de muncă al persoanei care ocupă postul, în condiţiile legii;
b. trecerea persoanei care ocupă postul pe un alt post din cadrul aceleiaşi organizaţii de cercetare, ca urmare a câştigării unui concurs;
c. prin suspendarea contractului individual de muncă al persoanei care ocupă postul, în acest caz, postul temporar vacant putând fi ocupat pe perioadă determinată până la revenirea titularului pe postul respectiv.

Articolul 12. Procedura de concurs este demarată de către IBPC-NS numai după aprobarea organizării concursului de către Consiliul Științific.

Articolul 13. Calendarul de derulare a concursurilor pentru ocuparea posturilor vacante:
a. se întocmește nota de fundamentare prin care se propune scoaterea la concurs a postului și se înaintează spre aprobare Consiliului Științific al IBPC-NS;
b. după primirea aprobării, concursul se anunță public, prin afișare pe site-ul IBPC-NS și prin publicare pe https://posturi.gov.ro/.ro;

c. se stabilește componența comisiei de concurs/soluționare a contestațiilor în termen de 5 zile de la aprobarea organizării concursului și a calendarului de desfășurare și se întocmesc deciziile de numire a membrilor și de desemnare a președinților de comisie;
d. intervalul disponibil pentru depunerea dosarului de concurs este de 30 zile (pentru posturile pe perioadă nedeterminată) de la data publicării anunțului;
e. dosarele de concurs se transmit președintelui comisiei de concurs;
f. sunt admiși și pot fi recomandați candidații care au obținut cel puțin media 8 și nici o nota sub 7;
g. în termen de 1 zi lucrătoare de la data publicării rezultatului concursului, candidații au dreptul să depună contestație;
h. contestațiile se soluționează în termen de 2 zile lucrătoare de la înregistrarea lor;
i. raportul final al concursului, după aprobarea de către Consiliul Științific, este înaintat către Director;
j. în termen de 2 zile lucrătoare de la finalizarea concursului se publică rezultatul final al concursului;
k. dosarele de concurs câștigătoare sunt înaintate Secției de Științe Biologice în termen de 10 zile calendaristice de la finalizarea concursului;
l. procedura de concurs trebuie finalizată de comisie în cel mult 15 zile de la data încheierii înscrierilor, iar raportul final și dosarul complet trebuie depuse la Prezidiul Academiei Române în maximum 45 de zile de la aceeași dată.

Capitolul IV. Publicarea anunțului privind organizarea concursului

Articolul 14. Concursul se anunţă public prin afișare la sediul IBPC-NS, pe pagina de internet a IBPC-NS (www.icbp.ro) și pe site-ul https://posturi.gov.ro/.ro, putând fi distribuit și pe alte platforme online naționale si internaționale, sau în forma printată în diverse locații pentru a vizibilitate crescută. Toate anunțurile conțin elemente referitoare la data-limita pâna la care se pot depune dosarele, pagina de internet a IBPC-NS și datele de contact ale secretariatului IBPC-NS, de unde pot fi obținute eventuale informații suplimentare referitoate la concurs.

Articolul 15. Simultan cu publicarea anunţului de concurs, pe site-ul IBPC-NS se publică şi formularele-tip (cererea pentru înscrierea la concurs, Anexa 1A, propunerea de dezvoltare a carierei științifice, Anexa 5 și fișele de verificare a îndeplinirii standardelor proprii organizației de cercetare, Anexele 5A, 5A.1-5A.3 și 5Aa) și următoarele elemente:
a. scurtă descriere a postului pentru care se organizează concurs (poziția, codul COR, durata contractului individual de muncă, atribuţii specifice);
b. salariul minim de încadrare corespunzător postului;
c. tematica şi bibliografia probelor de concurs;
d. lista completă a documentelor ce alcătuiesc dosarul de concurs;
e. adresa la care se poate transmite dosarul de concurs (în format fizic sau electronic);

f. modul de organizare al concursului (poba scrisă și/sau orală);
g. ziua, ora și locul desfăşurării concursului;
h. calendarul/descrierea procedurii concursului.

Capitolul V. Înscrierea la concurs

Articolul 16. Înscrierera la concurs se face în termen de 30 de zile calendaristice de la data publicării anunţului, prin depunerea de către candidat a unui dosar atât în format fizic, la sediul IBPC-NS, cât și în format electronic (pe memory stick la sediul IBPC-NS și la adresa de e-mail indicată în anunț).

Articolul 17. Dosarul trebuie să conțină următoarele documente prevăzute și în Anexa DA (fiecare document din dosarul fizic va fi scanat conform unui opis, Anexa 6A și salvat pe un memory stick):

a. cererea de înscriere la concurs semnată, la care se anexează o declaraţie pe propria răspundere prin care candidatul atestă veridicitatea informaţiilor prezentate în dosar (Anexa 1A și Anexa 3A);
b. propunerea de dezvoltare a carierei ştiinţifice din punctul de vedere al activităţilor de cercetare ştiinţifică (Anexa 5), de maximum 5 pagini, semnată (pentru CSI, CSII, CSIII);
c. curriculum-ul vitae după model EUROPASS semnat de către candidat (Anexa 3), obligatoriu să conțină: i. studiile efectuate şi diplomele obţinute; ii. experienţa profesională şi locurile de muncă relevante ocupate anterior; iii. proiectele de cercetare, dezvoltare şi inovare pe care le-a condus ca director de proiect şi granturile obţinute, dacă este cazul, indicându-se pentru fiecare sursa de finanţare, volumul finanţării şi principalele publicaţii sau brevete de invenţie rezultate; iv. premiile sau alte elemente de recunoaştere a contribuţiilor ştiinţifice; v. descrierea narativă a celor mai importante 3 realizări de la ultima promovare-maximum 3 pagini;
d. lista publicaţiilor, lucrărilor, articolelor/studiilor, brevetelor de invenţie selectate de candidat în funcţie de relevanţa pentru activităţile de cercetare ştiinţifică proprii, semnate în original de către candidat (Anexa 4). Lista trebuie să conțină obligatoriu: i. lista a cel mult 10 publicaţii ştiinţifice, cele mai relevante, precum: cărţi de autor, articole/studii/capitole, volume editate, lucrări; ii. lista brevetelor de invenţie şi a altor titluri de proprietate industrială; iii. lista cărţilor de autor şi a volumelor editate şi publicate; iv. lista articolelor/studiilor in extenso, publicate în reviste din fluxul ştiinţific internaţional principal; v. lista altor lucrări şi contribuţii ştiinţifice;
e. fişa de verificare a îndeplinirii standardelor proprii ale organizaţiei de cercetare, completată şi semnată de către candidat (Anexele 5A), cu excepţia situaţiei reglementate la lit. f;
f. dovada deţinerii gradului profesional de cercetare-dezvoltare corespunzător postului pentru care candidează, fişa de verificare a îndeplinirii standardelor proprii ale organizaţiei de cercetare, completată şi semnată de către candidat, doar pentru candidaţii care deţin gradul profesional de cercetare-dezvoltare de CS II sau CS I corespunzător postului pentru care

candidează;

g. copia diplomei de licenţă sau echivalentă/masterat/doctorat, după caz. În situaţia în care candidatul declarat câştigător nu deţine o diplomă eliberată de o instituţie de învăţământ superior din România, acesta trebuie să depună o copie conform cu originalul a atestatului de recunoaştere sau de echivalare a acesteia înainte de încadrarea pe post şi semnarea contractului individual de muncă, sub sancţiunea neemiterii actului administrativ de încadrare pe post;
h. copia actului de identitate sau orice alt document care atestă identitatea, potrivit legii, după caz, certificată de către candidat conform cu originalul, numele în clar și semnătura;
i. copia certificatului de căsătorie sau dovada schimbării numelui, după caz, certificată de către candidat conform cu originalul, numele în clar și semnătura;
j. certificatul medical care să ateste starea de sănătate corespunzătoare, eliberată de către medicul de familie al candidatului sau de către unităţile sanitare abilitate cu cel mult 3 luni anterior derulării concursului;
k. declaraţia de consimţământ pentru prelucrarea datelor cu caracter personal semnată (Anexa 4A);
l. certificatul de cazier judiciar;
m. certificatul de naștere, certificat de către candidat conform cu originalul, numele în clar și semnătura.

Dosarul de concurs pentru ocuparea postului de CSI, CSII se constituie din 2 părți (dosarul administrativ și mapa cu lucrări științifice), iar documentelelor conținute (conform anexei DA) li se va atribui câte un link conform pașilor procedurali din Anexa L.

Articolul 18. Secretarul comisiei de concurs înregistrează dosarul de concurs, comunică numărul de înregistrare candidatului şi transmite dosarul membrilor comisiei de concurs, în condiţiile stabilite prin regulamentul propriu de concurs.

Articolul 19. Secretarul comisiei de concurs verifică dacă dosarul de concurs este complet în ziua primirii şi înregistrării acestuia. În situaţia în care dosarul de concurs este incomplet, secretarul comisiei de concurs solicită candidatului clarificări, iar acesta poate completa dosarul de concurs până la data la care expiră perioada de depunere a dosarelor de concurs.

Articolul 20. În exercitarea atribuţiilor prevăzute la artic. 18 și 19, secretarul comisiei de concurs colaborează cu responsabilul de resurse umane, în condiţiile prevăzute în regulamentul propriu de concurs.

Capitolul VI. Comisia de concurs şi comisia de soluţionarea a contestaţiilor

Articolul 21. În termen de 5 zile de la aprobarea organizării concursului şi a calendarului de desfăşurare, se stabilește componența nominală a comisiei de concurs și a celei de soluționare a contestațiilor, pentru fiecare post vacant pentru care se organizează concurs, ca urmare a propunerilor

directorului/secretarului științific, aprobării în Consiliul Științific al IBPC-NS și avizării de către Secția de Științe Biologice a Academiei Române.

Articolul 22.
(1) Membrii comisiei de concurs și cei ai comisiei de soluționare a contestațiilor sunt cercetători științifici sau cadre didactice universitare cu gradul profesional sau titlul didactic universitar cel puțin egal cu gradul profesional pentru care se organizează concursul și sunt specialiști în domeniul disciplinelor postului vacant sau în domenii apropiate.
(2) Membrii comisiei de concurs nu pot face parte din comisia de soluţionare a contestaţiilor.
(3) Sunt implicate în procedura de concurs persoanele care:
a. participă în procesul de decizie referitor la numirea comisiei de concurs şi a comisiei de soluţionare a contestaţiilor;
b. participă la evaluarea profesională sau administrativă în cadrul concursului.
(4) Nu pot fi implicate în procedura de concurs persoanele care au calitatea de soţ/soţie, rudă sau afin până la gradul al III-lea inclusiv în raport cu candidatul la concursul pentru ocuparea unui post vacant de cercetare.

Articolul 23. Componența comisiei de concurs se numește prin act administrativ al directorului IBPC-NS și este alcătuită:
a. din 3 membri, în cazul concursului pentru ACS, CS și CSIII;
b. din 5 membri, din care cel puțin 3 sunt din afara IBPC-NS, pentru CSII și CSI.

Articolul 24. Componența comisiei de soluționare a contestațiilor se numește prin act administrativ al directorului IBPC-NS și este alcătuită din 3 membri.

Articolul 25. Lucrările comisiei de concurs și ale celei de soluționare a contestațiilor sunt conduse de unul dintre cei doi membri fiecărei comisii în parte, cu afiliere la IBPC-NS, în calitate de președinte, numit prin decizie de către Directorul IBPC-NS.

Articolul 26. Comisia de concurs şi comisia de soluţionare a contestaţiilor beneficiază de suport administrativ din partea IBPC-NS, asigurat de un secretar numit prin act administrativ al Directorului, care nu este membru al comisiei de concurs şi nu ia parte la deciziile comisiei.

Articolul 27. În situaţii bine justificate, imbolnavire, deplasare internă/externă (interes de serviciu), cel mult un membru al comisiei de concurs poate participa în sistem de videoconferinţă online. Înregistrarea ședinței va face parte din dosarul de concurs.

Articolul 28. Deciziile comisiei de concurs și cele ale comisiei de soluționare a contestațiilor se iau prin votul deschis al membrilor şi trebuie să întrunească votul favorabil a cel puțin jumătate plus unu din numărul membrilor componenți.

VII. Evaluarea concursului

Articolul 29. Concursul constă în evaluarea activităţii ştiinţifice şi a competenţelor privind cercetarea ale candidaţilor pentru posturile vacante scoase la concurs, conform criteriilor de evaluare și a grilelor proprii de notare stabilite intern și aprobate de Consiliul Științific al IBPC-NS (Anexa SC.C și Anexa GN).

Articolul 30. Concursul pentru ocuparea posturilor vacante de ACS şi CS constă în *probe scrise, orale şi/sau practice şi de dosar,* specifice postului și se evaluează după cum urmează:

a. rezultatul probelor de concurs se apreciază de fiecare membru al comisiei de concurs prin note de la 1.00 la 10.00;
b. nota fiecărei probe de concurs reprezintă media aritmetică a notelor acordate de fiecare membru al comisiei de concurs;
c. punctajul final reprezintă media aritmetică a notelor probelor de concurs;
d. un candidat poate fi declarat câştigător numai dacă a obţinut punctajul final cel puţin 8.00 şi nicio notă sub 7.00 la probele de concurs;
e. Consiliul Științific analizează respectarea procedurilor stabilite prin regulamentul propriu de concurs şi aprobă raportul asupra concursului prin vot nominal deschis;
f. ponderea probelor de concurs în rezultatul final se calculează după cum urmează:
    i) pentru ACS: proba scrisă (50%), proba orală (50%)
    ii) pentru CS: evaluare dosar (33,3%), proba scrisă (33,3%), proba orală (33,3%)

Articolul 31. Concursul pentru ocuparea posturilor vacante de CSIII, CSII şi CSI constă în *analiza dosarului de înscriere la concurs* şi acordarea punctajului, pe baza unei grile adaptate specificului activităţii locului de muncă al candidatului şi a performanţelor sale, putând *include şi o probă de interviu*. Procesul de evaluare se desfăşoară după cum urmează:

a. după analiza dosarului de concurs, fiecare membru al comisiei de concurs acordă un punctaj, pe baza unei grile adaptate specificului activităţii locului de muncă a candidatului, în acord cu pragurile stabilite prin standardele minimale şi prin standardele proprii ale organizaţie de cercetare, după caz;
b. punctajul individual acordat de un membru al comisiei de concurs reprezintă suma punctajelor obţinute de candidat, aferentă fiecărui prag cantitativ din standardele proprii ale organizaţiei de cercetare.
c. punctajul total reprezintă media aritmetică a punctajelor individuale acordate de membrii comisiei;
d. în cazul în care concursul include şi o probă de interviu, se acordă un punctaj care reprezintă media aritmetică a punctajelor acordate de membrii comisiei;
e. punctajul maxim al probei interviu nu poate depăşi 20% din punctajul total calculat;
f. punctajul final reprezintă suma punctajelor acordate în urma analizării dosarului și a interviului;
g. Consiliul Ştiinţific analizează respectarea procedurilor stabilite prin regulamentul propriu de

concurs şi aprobă raportul asupra concursului, prin vot nominal deschis;

h. ponderea probelor de concurs în rezultatul final se calculează după cum urmează:
   i) pentru CSIII: evaluare dosar (80%) și proba interviu (20%);
   ii) pentru CSI și CSII: evaluare dosar (100%).

Articolul 32. Rezultatul concursului este analizat și aprobat de Consiliul Științific al IBPC-NS, punctajul final fiind calculat conform formulelor:

a. pentru ACS: Pfinal = (Pscris + Poral)/2;
b. pentru CS: Pfinal = (Pscris + Poral + Pdosar)/3;
c. pentru CSIII: Pfinal = Pdosar × 80% + Pinterviu × 20%;
d. pentru CSII și CSI: Pfinal = Pdosar.

Articolul 33. În cazul în care concursul include probe scrise, orale şi/sau practice, respectiv interviu, comisia de concurs evaluează candidatul din perspectiva următoarelor criterii necumulative:

a. relevanţa rezultatelor activităţii de cercetare şi/sau inovare, în relaţie cu tematica postului pentru care candidează;
b. impactul activităţii de cercetare şi/sau inovare şi al rezultatelor ştiinţifice ale candidatului, în relaţie cu tematica postului pentru care candidează, reflectat în publicaţii ştiinţifice;
c. anvergura internaţională a activităţilor, reflectată în publicaţii ştiinţifice, brevete de invenţie, participări la conferinţe ştiinţifice, colaborări individuale şi instituţionale, proiecte, burse prestigioase, calitatea de profesor/cercetător invitat, de membru în colegiile de redacţie ale unor reviste de top din domeniu;
d. capacitatea de a atrage fonduri de cercetare sau de a colabora cu organizaţii publice şi/sau private de cercetare şi de a conduce proiecte de cercetare-dezvoltare;
e. prestigiul profesional;
f. capacitatea organizatorică;
g. capacitatea de a îndruma tineri cercetători sau studenţi;
h. capacitatea de a transfera cunoştinţele şi rezultatele către mediul economic sau social ori de a populariza propriile rezultate ştiinţifice;
i. capacitatea de a lucra în echipă şi eficienţa colaborărilor ştiinţifice ale acestuia, în funcţie de specificul domeniului candidatului;
j. experienţa profesională în alte instituţii decât instituţia organizatoare de concurs.

Capitolul VIII. Rezultatele concursului

Articolul 34.

(1) În urma finalizării procesului de evaluare, comisia de concurs stabileşte, pentru fiecare post, ierarhia candidaţilor şi nominalizează candidatul care a obţinut cele mai bune rezultate în raport cu punctajul final calculat.

(2) Preşedintele comisiei de concurs întocmeşte un raport asupra concursului (Anexa 3C), semnat de fiecare membru al comisiei și realizat pe baza referatelor de apreciere (Anexa 2C) redactate de

fiecare membru al comisiei de concurs şi cu respectarea ierarhiei candidaţilor decise de comisia de concurs.
(3) Consiliului Ştiinţific, în urma analizei raportul și documentației aferente primite de la președintele comisiei de concurs, verifică respectarea procedurilor stabilite prin regulamentul propriu de concurs şi aprobă sau nu raportul asupra concursului, prin vot nominal deschis. Consiliul Științific nu poate modifica ierarhia candidaţilor rezultată în urma evaluării realizate de comisia de concurs.
(4) După avizarea dosarelor și aprobarea raportului comisiei de concurs de către Consiliul Științific, acesta este înaintat Directorului IBPC-NS.

Articolul 35.
(1) Dosarele de concurs pentru obținerea gradelor de ACS, CS, CSIII, CSII şi CSI se depun de către IBPC-NS în termen de 10 zile calendaristice de la finalizarea concursului la Secția de Științe Biologice, care în termen de maximum 15 zile calendaristice, va analiza dosarul pentru conferirea gradului profesional de cercetare-dezvoltare. În cazul avizării favorabile, va înainta spre verificare dosarul Serviciului Juridic și Comunicare.
(2) Serviciul Juridic și Comunicare va aviza dosarul privind legalitatea desfășurării concursului în termen de maximum 15 zile calendaristice de la primirea dosarului de la Secția de Științe Biologice. În cazul avizării favorabile, va înainta dosarul Serviciului Programe de Cercetare și Doctorat.
(3) Serviciul Programe de Cercetare și Doctorat va înainta spre aprobare Prezidiului Academiei Române, în termen de maximum 5 zile calendaristice, dosarele de concurs care au obținut avizului favorabil al Secției de Științe Biologice și al Serviciului Juridic și Comunicare.
(4) După aprobarea rezultatelor examenului de promovare de către Prezidiul Academiei Române, dosarele se restituie IBPC-NS.

Articolul 36.
(1) În situaţia în care, în urma analizei administrative, se constată că dosarul de concurs este incomplet ori nu respectă reglementările legale în vigoare, precum şi prevederile regulamentului propriu de concurs al institutului, se returnează dosarul de concurs la IBPC-NS.
(2) În termen de 15 zile de la data restituirii, IBPC-NS are obligaţia actualizării acestuia, astfel încât să fie respectate prevederile legale şi să îl retrimită către Secția de Științe Biologice/Serviciul care a constatat nerespectarea reglementărilor legale în vigoare.
(3) Dacă nu este posibilă completarea dosarului candidatului declarat câştigător, astfel încât să respecte reglementările legale în vigoare, precum şi prevederile regulamentului IBPC-NS, candidatul de pe locul imediat următor este declarat câştigător, iar dosarul acestuia se transmite către Secția de Științe Biologice/Serviciul care a constatat nerespectarea reglementărilor legale în vigoare, în vederea analizei administrative, cu respectarea prevederilor alin. (1).
(4) În cazul în care nu mai există niciun candidat care să îndeplinească condiţiile, concursul se reia fără a mai fi necesară o nouă aprobare în vederea organizării acestuia.

Articolul 37.
(1) Durata și finalizarea concursului este de 15 zile calendaristice de la data încheierii înscrierii la concurs, la nivelul comisiei de concurs și de 45 de zile calendaristice până la depunerea raportului comisiei de concurs și a dosarului ce conține documentele aferente concursului către Prezidiul Academiei Române.
(2) Rezultatul concursului se afișează la sediul IBPC-NS şi pe site-ul acestuia, în termen de 2 zile lucrătoare de la finalizarea concursului.

Articolul 38.
(1) Candidații la concurs nemulțumiți de decizie, pot formula contestații în termen de 1 zi lucrătoare de la data publicării rezultatului concursului, care vor fi depuse la aceeași adresă de e-mail din anunț.
(2) Secretarul comisiei înaintează contestațiile comisiei de soluționare a contestațiilor, care le va soluționa în termen de 2 zile lucrătoare de la înregistrarea lor.
(3) Preşedintele comisiei de soluționarea contestațiilor întocmește un raport asupra contestațiilor (Anexa 3C) depuse, semnat de către fiecare membru al comisiei și realizat pe baza referatelor redactate (Anexa 2C) de către aceștia.
(4) Consiliului Ştiinţific, în urma analizei raportul și documentației aferente primite de la președintele comisiei de soluționare a contestațiilor, aprobă sau infirmă raportul asupra contestațiilor depuse, care în final este înaintat Directorului IBPC-NS.
(5) Rezultatele finale ale concursului sunt afișate și în termen de 5 zile lucrătoare de la afișare, trebuie să fie publicate pe site-ul institutului alaturi de CV-ul, Fișa de verificare a îndeplinirii standardelor proprii institutului și de Lista publicațiilor științifice ale candidatului declarat admis.
(6) În cazul în care postul vacant pentru care se organizează concursul nu a fost ocupat, concursul poate fi reluat, cu respectarea legislaţiei în vigoare.

Capitolul IX. Încadrarea pe post

Articolul 39. Gradele profesionale de ACS, CS, CSIII, CSII și CSI din IBPC-NS sunt acordate prin decizie a președintelui Academiei Române, în urma aprobării rezultatelor concursului public de către Prezidiul Academiei Române.

Articolul 40. IBPC-NS întocmește un raport sintetic (Anexa 7) privind organizarea și desfășurarea concursului, care se transmite anual, în termen de 15 zile calendaristice de la finalul anului calendaristic pentru care se face raportarea, atât în format fizic cu adresa de înaintare, către Serviciul Programe de Cercetare și Doctorat, cât și în format electronic la adresa de email bpg@acad.ro.

Articolul 41. Încadrarea pe posturi corespunzătoare funcțiilor și gradelor profesionale ale personalului CDI se realizează conform principiului meritului profesional, în baza unor proceduri

transparente și echitabile care respectă principiile generale și condițiile prevăzute de Carta Europeană a Cercetătorilor.

Articolul 42. Datele cu caracter personal ale persoanelor implicate în procesul de examinare sunt prelucrate în cadrul platformei informatice, cu respectarea prevederilor Regulamentului (UE) 2016/679 privind protecţia persoanelor fizice în ceea ce priveşte prelucrarea datelor cu caracter personal şi privind libera circulaţie a acestor date şi de abrogare a Directivei 95/46/CE (Regulamentul general privind protecţia datelor).

Articolul 43. Anexele SC.C, DA, L, 1-5GN, 1A-6A, 1C-4C, 1-9, 1.1C-1.3C, 2.1C și 2.2, fac parte din prezentul Regulament și împreună cu acesta, au fost stabilite și întocmite de către IBPC-NS în conformitate cu reglementările și modelele propuse de către Academia Română în cadrul Normelor metodologice privind organizarea concursului pentru ocuparea pozițiilor vacante de CDI din institutele Academiei Române/15 iulie 2025. Acestea reprezintă singurele documente recomandate pentru a fi utilizate în desfășurarea concursului, fiind puse la dispoziția întregului personal implicat în procedura de concurs, prin intermediul site-ului oficial al IBPC-NS și al partiției comune pe intranetul instituției.

Prezentul regulament, în forma sa revizuită, aprobat în ședința Consiliului Științific al IBPC-NS din la data de 13.01.2026, înlocuiește vechiul Regulament din data de 6.10.2025. În continuare, prezentul regulament poate fi ajustat prin calibrarea oferită de concursurile pentru fiecare categorie (grad științific) care se vor desfășura în continuare.

REGULAMENT PRIVIND ORGANIZAREA ŞI DESFĂȘURAREA CONCURSULUI DE ADMITERE LA STUDIILE UNIVERSITARE DE DOCTORAT

Metodologia organizării şi desfăşurării concursului de admitere la studiile universitare de doctorat

I. Norme de organizare

Concursul de admitere la studiile universitare de doctorat din anul 2026 pentru toate domeniile de doctorat din cadrul fiecărei Școli doctorale din cadrul Școlii de Studii Avansate a Academiei Române (SCOSAAR) se va desfășura conform legislaţiei în vigoare:

- ***Legea învăţământului superior nr. 199/2023 din 4 iulie 2023cu modificările și completările ulterioare;***
- ***Regulamentul - cadru privind studiile universitare de doctorat nr. 3.020/08.01.2024;***
- ***Ordinul Nr. 3693/2024 din 1 februarie 2024 pentru aprobarea Metodologiei-cadru privind organizarea admiterii în învăţământul superior în ciclurile de studii universitare de scurtă durată, de licenţă, de master şi de doctorat***

Concursul de admitere la doctorat se organizează de către Academia Română prin Școala de Studii Avansate a Academiei Române, abilitată să organizeze doctorate.

Concursul pentru admiterea la studiile universitare de doctorat se poate organiza, de regulă, în sesiunea din septembrie sau în două sesiuni, pentru școlile doctorale care consideră necesar acest demers, cu respectarea legislației în vigoare, în condiţii identice, înainte de începerea anului universitar, dar nu mai târziu de 30 septembrie. Locurile neocupate în prima sesiune vor fi reportate pentru sesiunea a 2-a, în condiţiile

Aceste informații vor fi aduse la cunoştinţă celor interesaţi prin afişare sau postarea pe pagina web. Studiile universitare de doctorat se organizează în general la forma cu frecvență, şi, în funcţie de opţiunile şi strategia fiecărei şcoli, cu frecvenţă redusă cu taxă.

II. Calendarul admiterii

Înscrierile şi concursul de admitere la studiile universitare de doctorat se desfășoară conform calendarului de desfășurare a concursului de admitere la doctorat, anexă la prezentul regulament.

Înscrierile la colocviul de admitere se vor face de regulă, în luna septembrie la institutele afiliate Școlilor doctorale. Colocviul de admitere la doctorat se va desfăşura în luna septembrie.

În cazul în care va exista și o altă sesiune de admitere, calendarul admiterii va fi stabilit de fiecare școală doctorală în parte, cu respectarea legislației în vigoare.

III. Pregătirea desfăşurării concursului de admitere

În vederea organizării concursului de admitere la doctorat, Școlile doctorale transmit către SCOSAAR situația cu numărul de locuri solicitate de către fiecare conducator de doctorat.

Consiliul Științific SCOSAAR (CSUD) analizează solicitările conducătorilor de doctorat privind numărul de locuri vacante finanțate. În această privință, se va ține cont de cerințele unei încărcări echilibrate pentru fiecare conducător de doctorat în vederea asigurării calității studiilor universitare de doctorat. Numărul maxim de locuri acordate unui conducător de doctorat este de 8. De asemenea, evaluarea presupune cunoașterea activității conducătorului de doctorat, ținând cont și de titlurile de doctor obținute de către studenții de doctorat coordonați.

Consiliul Științific SCOSAAR (CSUD) înaintează spre aprobare Prezidiului Academiei Române lista locurilor finanțate cu bursă sau finanțate fără bursă per conducător de doctorat/institut.

De asemenea, conducătorul de doctorat propune/nominalizează comisia de îndrumare și integritate academică. Componența comisiei de îndrumare și intergitate academică este aprobată prin decizie semnată de către directorul SD.

Conducătorii de doctorat transmit institutelor de cercetare ale Academiei Române tematicile și bibliografia aferentă colocviului de admitere în vederea afișării pe pagina web a institutelor.

Școlile doctorale primesc de la institutele afiliate tematicile și bibliografia aferentă colocviului de admitere și le transmit către SCOSAAR în vederea afișării pe pagina web a SCOSAAR

Școlile doctorale elaborează şi adoptă regulamente proprii de admitere, care apoi vor fi supuse aprobării CSD, Directorului şcolii respective și CSUD. Aceste regulamente vor trebui să cuprindă:

- Forma de desfăşurare a concursului de admitere, inclusiv structura probelor din cadrul acestuia şi organizarea a una sau mai multe comisii sau subcomisii de admitere;
- Tematica concursului de admitere şi bibliografia comună, dacă este cazul;
- Criteriile de evaluare şi criterii de departajare a candidaţilor;
- Pentru institutele de cercetare care organizează admiterea cu ajutorul mai multor comisii sau subcomisii, se va prevedea explicit modul în care se va realiza clasificarea tuturor candidaţilor dintr-un domeniu de doctorat pe o listă unică, în ordinea descrescătoare a mediilor generale obţinute de candidaţi, în vederea alocării locurilor cu bursă/stipendium.
- Modul de soluţionare a contestaţiilor la probele scrise, dacă este cazul;

După aprobare, aceste regulamente se afișează pe pagina web a institutelor de cercetare unde se desfășoară concursul de admitere la doctorat.

Regulamentele proprii de admitere pot prevedea posibilitatea susţinerii online a concursului de admitere.

Școlile doctorale vor desemna comisiile de admitere şi, după caz, comisiile de soluţionare a contestaţiilor.

IV. Condiţii generale de înscriere la concurs

Înscrierea la concursul de admitere se face personal de către candidat sau de către altă persoană cu procură notarială pe baza actului de identitate.

Cu ocazia înscrierii la concursul de admitere, candidatul la studiile universitare de doctorat își alege un conducător de doctorat dintre acei conducători de doctorat ai Școlii doctorale unde dorește să studieze și care are locuri vacante pentru concursul de admitere.

Înscrierea la concursul de admitere la studii universitare de doctorat în cadrul institutului unde se organizează admiterea la studiile universitare de doctorat nu este condiţionată de domeniul în care a fost dobândită diploma de licenţă sau masterat.

La colocviul de admitere la doctorat se pot prezenta absolvenţi ai studiilor universitare de masterat, dar şi absolvenţii cu diplomă de licenţă sau echivalentă (diploma de licenţă a absolvenţilor unor programe de studii de 5 sau 6 ani, forma de învăţământ "zi" - învăţământ de lungă durată), eliberată, de regulă, până în anul absolvirii primei promoţii de licenţă organizate în conformitate cu

prevederile Legii nr. 288/2004 privind organizarea studiilor universitare, cu modificările şi completările ulterioare.

La admiterea la studii universitare de doctorat se pot înscrie şi cetăţeni care nu fac parte din Uniunea Europeană, Spaţiul Economic European şi Confederaţia Elveţiană (extracomunitari). Recunoaşterea studiilor efectuate de către aceştia în afara României se va realiza de către direcţia de specialitate din cadrul Ministerului Educaţiei.

Admiterea românilor de pretutindeni, precum şi a cetăţenilor din state terţe Uniunii Europene se realizează în baza metodologiilor special elaborate de către Ministerul Educaţiei.

Durata totală cumulată a ciclului de studii universitare de licenţă şi masterat trebuie să fie de cel puţin 300 de credite transferabile (ECTS).

La înscriere se vor depune copii conform cu originalul după documentele solicitate; certificarea conformității cu originalul se face de către persoana/persoanele care are/au atribuţii desemnate în acest sens.

Prin excepţie, pe perioada instituirii stării de alertă, necesitate sau de urgenţă, în baza autonomiei universitare, se poate realiza înscrierea online prin încărcarea documentelor de către candidaţi cu asumarea responsabilităţii de către aceştia cu privire la autenticitatea şi corespondenţa dintre documentele digitale/scanate şi cele originale.

Înscrierile se vor face la institutele de cercetare afiliate Școlilor doctorale care organizează concurs de admitere la doctorat.

Pentru înscriere la colocviul de admitere la doctorat, candidaţii vor prezenta următoarele documente:

- cerere de înscriere – formular tip (Anexa 1);
- certificat de naştere, copie;
- certificat de căsătorie sau alt act de schimbare a numelui, copie;
- diplomă de bacalaureat, copie;
- diplomă de licenţă şi foaie matricolă, copie;
- diploma de master şi foaie matricolă, copie;
- cartea de identitate/pașaport, copie;
- atestat de susţinere a unui examen de competenţă lingvistică (nivelul minim B2, conform cadrului de referinţă al Consiliului Europei) , copie;
- alte certificate care atestă pregătire universitară şi /sau postuniversitară în domeniu, copie;
- curriculum vitae - model european (Partea a I - a:CV, Partea a II - a descrierea activităţii ştiinţifice);
- lista lucrărilor ştiinţifice publicate în domeniul de studiu ales;
- lista bibliografică cu literatura de specialitate studiată pentru colocviul de admitere;
- fişa de înscriere - formular tip (Anexa 2);
- propunere privind teza de doctorat ce urmează a fi elaborată şi o scurtă prezentare a acesteia -1, 2 pagini - formular tip (Anexa 3);
- adeverinţă de salariat în cazul in care candidatul este angajat;
- în cazul studiilor doctorale cu predare în limba română, pentru cetăţenii străini – certificatul de competenţă lingvistică privind cunoaşterea limbii române/sau să depună certificate/diplome care să dovedească parcurgerea a cel puțin 4 ani consecutivi de studii în România

Absolvenţii de studii universitare de masterat, promoţia anului în curs, pot depune la dosar adeverinţa de absolvire a studiilor universitare de masterat.

Candidaţii care au efectuat studiile în străinătate au obligaţia de a prezenta la înscriere traducerea diplomei obţinute şi a atestatului de recunoaştere a acestor studii eliberat de către direcţia de specialitate din cadrul Ministerului Educaţiei

Dosarele incomplete nu sunt acceptate la înscriere.

După încheierea perioadei de înscriere la concursul de admitere și până la concurs, opţiunea privind conducătorul de doctorat, tema de doctorat, precum şi alte informaţii, nu pot fi modificate.

Redistribuire locuri aprobate pentru admiterea la doctorat

A. Măsuri aplicabile înaintea examenului de admitere

Conducătorii de doctorat abilitați și afiliați unei școli doctorale în cadrul SCOSAAR ulterior procesului de aprobare a locurilor solicitate la doctorat precum și cei care constată necesitatea suplimentării numărului de locuri sau doresc să renunțe la locurile aprobate **îi** vor înștiința **cu privire la actualizarea numărului de locuri,** printr-o solicitare scrisă, **pe responsabilii de studii doctorale** ai institutelor. Responsabilii vor centraliza aceste informări și vor transmite Școlii Doctorale lista finală care cuprinde necesarul actualizat de locuri pentru admiterea la doctorat, precum și locurile rămase disponibile pentru redistribuire.

În vederea soluționării solicitărilor, înainte de începerea examenului de admitere, fiecare Școală Doctorală va analiza listele transmise de institute și va centraliza locurile rămase disponibile pentru redistribuire ca urmare a renunțării conducătorilor de doctorat la locurile aprobate.

Școala Doctorală va transmite către SCOSAAR lista actualizată de locuri pentru admiterea la doctorat.

Locurile disponibile vor fi redistribuite (**sau pot rămâne la această fază a procesului de admitere**) cu prioritate în cadrul aceleiași Școli Doctorale.

Dacă rămân locuri disponibile și după redistribuirea locurilor în cadrul fiecărei școli doctorale, directorul SCOSAAR poate decide repartizarea locurilor neocupate către școlile interesate de locuri suplimentare.

Pentru locurile devenite disponibile în urma redistribuirii au prioritate, în următoarea ordine, membrii Academiei Române, cercetătorii științifici CSI, cercetătorii științifici CSII, având în vedere totodată vechimea în activitatea doctorală, numărul studenților doctoranzi îndrumați care au obținut titlul de doctor.

Redistribuirea locurilor se va realiza cu respectarea limitei maxime de 8 doctoranzi/conducător de doctorat, iar locurile astfel redistribuite vor fi supuse avizării CSUD și aprobării Prezidiului Academiei Române.

Pentru a putea fi aplicabilă redistribuirea descrisă mai sus, fiecare şcoală doctorală va înainta spre completare conducătorilor de doctorate, înainte de fiecare sesiune de admitere, un document-declaraţie privind statutul de conducător de doctorat (*Formular de declarare a statutului conducătorului de doctorat, ANEXA la Regulamentul Școlii Doctorale de ..... din cadrul SCOSAAR*), care trebuie să conţină: 1. calitatea de membru al Academiei Române (nu este membru, este membru corespondent sau membru titluar); 2. funcţia şi statutul exact de conducător (gradul de cercetare şi dacă este doar abilitat sau conduce efectiv doctorate – are întâietate calitatea de conducător efectiv); 3. numărul de ani de experienţă (în calitate de abilitat/conducător de doctorate – are prioritate calitatea de conducător efectiv), numărul de doctoranzi coordonaţi care au obţinut deja titlul de doctor.

B. Măsuri aplicabile după finalizarea examenului de admitere

[redundant-scos/fără sens: Locurile neocupate în urma concursului pot fi repartizate înaintea începerii anului universitar, de la un conducător de doctorat la altul, cu acordul scris al celor implicaţi şi cu aprobarea directorului şcolii doctorale din care fac parte și a directorului SCOSAAR.]

În situația în care un candidat a parcurs integral etapele examenului de admitere, însă, din motive obiective și temeinic justificate, conducătorul de doctorat inițial nu poate asigura coordonarea acestuia, Școala Doctorală poate propune înmatricularea candidatului sub îndrumarea unui alt conducător de doctorat din cadrul aceleiași școli. Această măsură este permisă doar în situația în care noul conducător de doctorat dispune de locuri neocupate sau a solicitat suplimentarea acestora, sau nu are locuri neocupate (nou afiliat etc.) dar a formulat o cerere expresă (aprobată de directorul şcolii doctorale) în timpul examenului de admitere pentru a primi locul ocupat deja de doctorandul admis pe care îl va coordona, cu respectarea limitei maxime de 8 doctoranzi/conducător și cu condiția corelării tematicii propuse de candidat cu domeniul de expertiză al conducătorului desemnat.
Dacă rămân locuri disponibile și după concursul de admitere în cadrul fiecărei școli doctorale, directorul SCOSAAR poate decide repartizarea locurilor neocupate către școlile interesate de locuri suplimentare. Redistribuirea se va face în funcție de notele obținute de către candidați și de solicitările conducătorilor de doctorat cu respectarea numărului maxim de 8 doctoranzi/conducător de doctorat. Pentru locurile disponibile au prioritate membrii Academiei Române, cercetătorii științifici CSI, cercetătorii științifici CSII, având în vedere totodată vechimea în activitatea doctorală, numărul studenților doctoranzi îndrumați care au obținut titlul de doctor.

Pentru a putea fi aplicabilă redistribuirea descrisă mai sus, fiecare şcoală doctorală va înainta spre completare conducătorilor de doctorate, înainte de fiecare sesiune de admitere, un document-declaraţie privind statutul de conducător de doctorat (*Formular de declarare a statutului conducătorului de doctorat, ANEXA la Regulamentul Școlii Doctorale de ..... din cadrul SCOSAAR*), care trebuie să conţină: 1. calitatea de membru al Academiei Române (nu este membru, este membru corespondent sau membru titluar); 2. funcţia şi statutul exact de conducător (gradul de cercetare şi dacă este doar abilitat sau conduce efectiv doctorate – are întâietate calitatea de conducător efectiv); 3. numărul de ani de experienţă (în calitate de abilitat/conducător de doctorate – are prioritate calitatea de conducător efectiv), numărul de doctoranzi coordonaţi care au obţinut deja titlul de doctor.

În ceea ce priveşte cazul în care o şcoală optează pentru 2 sesiuni de admitere, procedura redistribuirii locurilor se aplică numai în interiorul şcolilor şi între şcolile care participă la sesiunea respectivă (de exemplu, dacă o şcoala optează doar pentru sesiunea din septembrie, locurile aprobate vor fi securizate până la demararea procesului de admitere în sesiunea din septembrie). Dacă o şcoală optează doar pentru prima sesiune, şi, în urma examenului de admitere, rămâm locuri libere, acestea se pot securiza în dreptul şcolii până înaintea începerii celei de-a doua sesiuni, când şcoala va decide dacă mai organizează sau nu o a doua sesiune. Dacă decide că nu o va face, va înştiinţa SCOSAAR în timp util prin procedura de mai sus în vederea cedării locurilor rămase libere către alte şcoli pentru sesiunea din septembrie.

O persoană poate beneficia de finanţare de la buget pentru un singur program de doctorat.

Orice alte detalii în legătură cu admiterea la studiile universitare de doctorat pot fi obţinute de la institutele din cadrul Academiei Române, în funcție de domeniul vizat, la care candidaţii doresc să susţină concursul.

SCOSAAR, prin Şcolile doctorale de la nivelul institutelor de cercetare, va lua măsuri pentru aducerea la cunoştinţa candidaţilor, prin afişare în termen legal, a tematicilor şi bibliografiilor pentru programele la care se organizează concurs de admitere.

V. Desfăşurarea concursului

Accesul candidaţilor în sala de concurs se face pe baza actului de identitate şi se consemnează în lista nominală prezenţa acestora. Este interzisă intrarea în sala de concurs cu telefoane mobile, calculatoare, agende electronice sau alte materiale.

Concursul de admitere la studiile universitare de doctorat se desfăşoară în cadrul institutelor de cercetare ale Academiei Române, în prezenţa comisiei de examinare. Conducătorul de doctorat face parte din comisia de admitere.

Admiterea propriu-zisă la studiile universitare de doctorat este procesul de selecţie a candidaţilor pentru fiecare poziţie vacantă de student-doctorand, aprobată de Prezidiul Academiei Române pentru respectivul conducător de doctorat.

Concursul are loc în limita locurilor libere ale fiecărui conducător de doctorat.

Concursul de admitere la doctorat este valabil numai pentru domeniul de doctorat pentru care s-a înscris candidatul. Concursul se organizează pe fiecare domeniu şi conducător de doctorat, pentru locurile finanţate cu bursă sau finanțate fără bursă, şi, după caz, pentru cele cu taxă, statutul candidaţilor admişi stabilindu-se în funcţie de opţiunea exprimată la data înscrierii şi de media la admitere.

Selecţia candidaţilor la doctorat pentru o poziţie vacantă este realizată de comisia de admitere, în limita locurilor vacante aprobate.

În urma probei de concurs, candidaţii sunt apreciaţi în raport cu nivelul de pregătire şi informare în domeniu, cu capacitatea de a evidenţia orientările majore ale cercetării în direcţia de cercetare propusă şi cu capacitatea de a formula soluţii şi căi de rezolvare (teoretică şi experimentală) a problemelor identificate.

Evaluarea candidaţilor la concurs se va realiza în raport cu următoarele criterii (Anexa 4):

1 - Nota obținută la proba orală, evaluată în raport cu:

- Definirea obiectivelor cercetării ştiinţifice (10% din evaluare);
- Metodologia cercetării (10% din evaluare);
- Rezultatele ştiinţifice ale candidatului în domeniul ales (articole, studii menţionate în CV sau alte activități științifice relevante) (20% din evaluare);
- Gandire logică: candidatul evocă date, fenomene, evenimente, răspunde organizat la subiecte complexe, dă răspunsuri logice, coerente, la subiect (10% din evaluare);
- Exprimarea clară și precisă a ideilor: răspunde exact la întrebările ce i-au fost adresate, accentuează ideile principale, formulează fraze complexe, dar comprehensibile, nu se pierde în cuvinte, termină ideea începută, ideile prezentate au o continuitate, decurgând logic (10% din evaluare);
- Nivelul de pregătire şi informare în domeniul de doctorat ales (bibliografie, tematică) (40% din evaluare).

2- Nota obținută la prezentarea proiectului tematic de cercetare va fi evaluată în raport cu:

- Contextul ştiinţific şi motivaţia temei alese (40% din evaluare);
- Rezultatele estimate (40% din evaluare);
- Calitatea prezentării proiectului (20% din evaluare).

VI. Rezultatele concursului

Media minimă de admitere la studiile universitare de doctorat este de 8 (opt), indiferent dacă locul este cu bursă, fără bursă sau cu taxă.

La fiecare probă de concurs, candidații trebuie să obțină cel puțin media 7 (șapte). Media se calculează cu două zecimale, fără rotunjire.

La medii de admitere cu punctaje egale, departajarea se va realiza în funcţie de media aritmetică dintre media de absolvire a studiilor universitare de licenţă şi media de absolvire a studiilor universitare de masterat. Prin excepţie, în cazul candidaţilor care au dreptul legal de a se înscrie la concursul de admitere la studiile universitare de doctorat fără a fi urmat studii universitare de masterat, pentru departajare se va lua în considerare media de absolvire a studiilor universitare de licenţă.

Calificativul admis/respins se stabilește în urma unui vot direct și secret al membrilor comisiei de evaluare. Rezultatele votului se regăsesc în procesul verbal atașat fiecărui dosar de candidatură evaluat/persoană.

Școala doctorală gestionează eventualele contestaţii înregistrate, în conformitate cu prevederile regulamentului propriu, şi afișează rezultatele derulării acestei proceduri.

(1) Eventualele contestaţii cu privire la rezultatele concursului de admitere se depun la institutul unde are loc concursul de admitere, în conformitate cu regulamentele de admitere specifice școlii doctorale.

(2) Nu se admit contestaţii pentru probele orale.

(3) Nu se admit contestaţii care au la bază necunoaşterea regulamentului propriu de admitere.

(4) După expirarea termenului de rezolvare şi de răspuns (prin afişare) la contestaţii, rezultatul concursului de admitere este definitiv şi nu mai poate fi modificat.

(5) Rezolvarea contestaţiilor este în exclusivitate de competenţa comisiei de contestaţii din cadrul institutului/școlii doctorale unde a avut loc concursul de admitere. Decizia comisiei de contestaţii este definitivă.

Rezultatele finale vor fi transmise către SCOSAAR pe adresa de email scosaar@acad.ro .

Candidaţii care îşi retrag actele de înscriere înainte de afişarea rezultatului final al concursului sunt consideraţi eliminaţi din concurs.

Rezultatele concursului de admitere vor fi validate de către Consiliul şcolii doctorale (CSD) şi Consiliul pentru studii universitare de doctorat (CSUD) și aprobate de către Prezidiul Academiei Române și se aduc la cunoştinţă prin afişare în termen de cel mult 48 de ore de la data finalizării acestuia.

Candidaţii declaraţi admişi sunt înmatriculaţi la studiile universitare de doctorat în baza rezultatului concursului prin decizia preşedintelui Academiei Române.

Dosarele candidaţilor respinşi sau ale celor care renunţă la şcolarizare se restituie candidaților, la cerere, în cel mult 48 de ore de la depunerea cererii, obligatoriu gratuit, pe baza actelor de identitate, după afișarea rezultatelor finale.

VII. Înmatricularea candidaţilor declaraţi admişi

După aprobarea rezultatelor admiterii de către Prezidiul Academiei Române se va realiza înmatricularea candidaţilor declaraţi admişi.

Înmatricularea candidaţilor declaraţi admişi în urma concursului de admitere se face prin decizia preşedintelui Academiei Române. După înmatriculare, studenţii doctoranzi sunt înscrişi în Registrul

matricol unic (RMU) cu un număr unic valabil pentru întreaga perioadă de şcolarizare la specializarea/ programul de studii la care au fost admişi.

Candidaţii declaraţi admişi semnează contractul de şcolarizare. Aceştia vor întocmi, împreună cu conducătorul de doctorat, planul studiilor universitare de doctorat, semnat olograf. De asemenea, conducătorul de doctorat propune/nominalizează componenţa comisiei de îndrumare și integritate academică, conform Regulamentului Şcolii Doctorale din cadrul IOSUD Şcoala de Studii Avansate a Academiei Române (SCOSAAR).

Comisia de îndrumare și integritate academică este compusă din **trei membri**, cercetători cu experiență care dețin titlul de doctor, din care cel puțin unul provine de la o altă instituție. Componența comisiei de îndrumare și intergitate academică se stabilește în termen de cel mult 30 zile de la data înmatriculării și se aprobă prin decizie semnată de către directorul SD.

Institute of Cellular Biology and Pathology

"Nicolae Simionescu"

B. P Hașdeu Street, No.8, Sector 5, Bucharest, Romania

Phone:021.319.45.18; www.icbp.ro

REGULATION

on the organization of the promotion exam for obtaining the professional degrees CSIII, CSII and CSI within the "Nicolae Simionescu" Institute of Cellular Biology and Pathology of the Romanian Academy

Approved,

Section of Biological Sciences of the Romanian Academy

Chapter I. General Provisions

Article 1.

The scientific career development of the research and development staff employed at the Institute of Cellular Biology and Pathology "Nicolae Simionescu" (ICBP-NS) of the Romanian Academy is ensured and carried out through promotion to the next higher professional grades.

Article 2.

Promotion is carried out through an examination organized in accordance with the provisions of Law 53/2003 on the Labor Code, Law 183/2024 on the Status of Research, Development and Innovation (RDI) personnel, Order of the Ministry of National Education and Scientific Research no. 6129/20.12.2016, the Methodological Norms on the organization of the promotion examination for obtaining higher professional research grades issued by the Romanian Academy on July 15th, 2025, and in accordance with this regulation.

Article 3.

This Regulation includes the methodology regarding the organization of the promotion examination for obtaining higher professional research grades: CSIII, CSII, and CSI at ICBP-NS.

Article 4.
Promotion to professional grades of already employed RDI personnel is carried out by transforming the occupied position into an immediately higher position, corresponding to the professional grade obtained through the examination.

Article 5.
Scientific researchers at ICBP-NS are differentiated by functions and professional research and development grades, maintaining equivalence with the professional grades provided in the European Charter for Researchers, as follows:

(i) Scientific Researcher Grade I (CSI), equivalent to Principal Senior Researcher R4, holding a PhD;
(ii) Scientific Researcher Grade II (CSII), equivalent to Established Senior Researcher R3, holding a PhD;
(iii) Scientific Researcher Grade III (CSIII), equivalent to Recognized Researcher R2, holding a PhD;
(iv) Scientific Researcher (CS), equivalent to Junior Researcher R1, holding a PhD or being a PhD student;
(v) Assistant Scientific Researcher (ACS), equivalent to Assistant in Scientific Research, holding a Bachelor's degree.

Article 6.
The number of RDI positions financed by the annual State Budget Law is established annually by the Romanian Academy, which will allocate the budget line accordingly and with the approvals of the Ministry of Public Finance.

Article 7.
The promotion examination is organized at the decision of the ICBP-NS management, depending on available financial resources and human resources policy, within the approved budgets and in compliance with legal provisions.

Article 8.
Employment in RDI positions is carried out through competition/examination, which is organized based on the following principles:

a. the principle of transparency, competence, gender equality, non-discrimination, and equal and fair access to filling vacant positions and promotion to a higher professional grade;
b. the principle of ensuring the quality and professional training of research staff;
c. correct and complete information regarding the organization and conduct of competitions/promotion examinations;
d. transparency regarding administrative, financial, and evaluation information of research positions in accordance with current legislation.

Chapter II. Minimum Training Conditions

Article 9.
The promotion examination is organized at the decision of the ICBP-NS management, following the request of the person who meets the provisions of Law no. 183/2024 regarding the necessary

conditions for registration, paragraphs (10) and (11), and the minimum standards specific to each scientific field, paragraph (1); as well as the additional standards established within the Institute of Cellular Biology and Pathology "Nicolae Simionescu" of the Romanian Academy (Annex SC).

Article 10.
The criteria on which the minimum standards for occupying the functions and professional grades of the RDI staff from ICBP-NS are based are as follows:
a. results of research and/or innovation activity;
b. impact of research and/or innovation activity;
c. ability to attract research funds or to collaborate with public and/or private research organizations;
d. professional prestige;
e. organizational capacity;
f. capacity for international cooperation.

Article 11.
The minimum standards for the professional research-development grades established by the Romanian Academy are:
(1) For the professional grades CSII and CSI, the minimum standards are approved by order of the Minister of Education;
(2) For the professional grade CSIII, the minimum standards are:
a. to hold a doctoral degree in the specialty or in related fields;
b. at least five articles published in journals indexed in the Web of Science – Core Collection;
c. at least one paper presented at an international conference.

Article 12.
The additional necessary and mandatory minimum standards established by ICBP-NS for the evaluation of candidates' professional activity are presented in Annex SC of the Procedure regarding the recruitment, selection, and promotion of RDI staff. These are established and approved by the Scientific Council of ICBP-NS and do not derogate from the minimum standards provided by law.

Article 13.
Scientific researchers CS, CSIII, and CSII, who exceed by at least 50% at least two-thirds of the institute's own minimum standards, provided in Article 12, may take the examination for promotion to the next professional grade within ICBP-NS of the Romanian Academy, with which they have an indefinite-term individual employment contract, and may be promoted by signing an additional act to the existing individual employment contract. All the minimum standards included in the annex provided for in Article 12 must be met, and two-thirds of the institute's own minimum standards, whichever they may be, must be exceeded by at least 50%.

Chapter III. Conduct of the Examination

Article 14.
The calendar for conducting examinations at ICBP-NS, for filling vacant positions, is as follows:
a. the application for registration to the examination is drawn up and submitted for approval to the Scientific Council of ICBP-NS (Annex 1P);
b. registration for the examination and submission of the examination file is carried out within a

maximum of 30 calendar days, according to the schedule in the announcement for the promotion examination, published on the institute's website;
c. decisions are drawn up with the composition of the examination/appeals commissions and the designation of the commission president;
d. the examination files are submitted to the president of the examination commission, after being previously registered and verified by the secretary of the examination commission, for analysis;
e. the entire examination procedure must be completed within 15 days from the closing date of registration, at the level of the examination commission, and within 45 days from the submission of the commission's report and file to the Presidium of the Romanian Academy;
f. within a maximum of 2 days from the communication of the result, candidates have the right to file an appeal;
g. within a maximum of 2 working days from the completion of the examination, the final result of the examination is communicated.

Article 15.
Members of the examination commission are scientific researchers or university teaching staff with a professional grade or university teaching title at least equal to the professional grade for which the examination is organized. The work of the examination commission is led by one of its members, as president, appointed by decision of the Director of ICBP-NS. The composition of the commission is:
a. 3 members, in the case of the examination for CS and CSIII;
b. 5 members, of which at least 3 are from outside ICBP-NS, for CSII and CSI.

Article 16.
The promotion examination for obtaining the professional grades of CSIII, CSII, and CSI consists of:
c. analysis of the application file for the examination, which must contain the documents provided in Annex DP (only the standard forms approved by ICBP-NS according to this Regulation will be used: Annexes 1P–5P, drawn up according to the models proposed in the Methodological Norms on organizing the promotion examination for obtaining professional grades of RDI staff in institutes of the Romanian Academy / July 15, 2025);
d. verification of compliance with the conditions provided in Articles 11 and 12;
e. awarding of scores based on evaluation according to the annex provided in Article 12.

Article 17.
The results of the evaluation process are recorded by each member of the examination commission in an assessment report (Annex 2E), on the basis of which the president of the examination commission prepares a report on the examination, signed by each member, and proposes the granting of the professional research-development grade to the respective candidate.

Article 18.
The Scientific Council analyzes compliance with the procedures established by the regulation and approves or rejects the examination report, by open nominal vote.

Article 19.
Candidates dissatisfied with the examination result may submit appeals, which will be resolved within 2 working days from their registration, by the appeals resolution commission, composed of:
a. president and 2 members, scientific researchers or university teaching staff, in the case of

commissions for resolving appeals submitted following examinations for filling research execution positions;
b. 3 members, namely one member from the specialized section of the Romanian Academy, Section of Biological Sciences , who is also the President of the commission, and 2 members from ICBP-NS holding CSI grade, in the case of commissions for resolving appeals submitted following examinations for filling research management positions.
c. the secretary of the appeals resolution commission will be appointed from within ICBP-NS by decision of the Director of ICBP-NS.

Article 20.
The examination commission and the appeals resolution commission benefit from administrative support from the research organization, provided by a secretary appointed by administrative act of the head of the research organization, who is not a member of the commission and does not take part in the commission's decisions. The standard forms used by the members of the commissions will be those proposed and approved in accordance with this Regulation (Annexes 1E and 2E, drawn up according to the models proposed in the Methodological Norms on organizing the promotion examination for obtaining professional grades of RDI staff in institutes of the Romanian Academy / July 15, 2025).

Article 21.
The promotion examination files for obtaining the professional grades of CSIII, CSII, and CSI are submitted by ICBP-NS within 10 calendar days from the completion of the examination to the Section of Biological Sciences of the Romanian Academy.

Chapter IV. Results of the Examination and Appointment to the position

Article 22.
Following the approval of the favorable examination result conducted at ICBP-NS by the Presidium of the Romanian Academy, the President of the Romanian Academy issues the decision for employment and granting of the professional research-development grade of CSIII, CSII, or CSI to the promoted candidate, in accordance with the provisions of Article 10 of Law no. 183/2024.

Article 23.
After the approval of the results of the promotion examination by the Presidium of the Romanian Academy, the file is returned to ICBP-NS.

Article 24.
Under the conditions of Article 4, if the researcher passes the examination, they will be employed in the position corresponding to the professional grade obtained through the examination, by signing an additional act to the existing individual employment contract. The position corresponding to the higher research grade resulting from the transformation of the position previously held by the person before promotion will be budgeted no later than the year following the one in which the promotion took place, and the additional act to the individual employment contract will be concluded starting no later than January 1 of the year following the one in which the promotion examination was passed, based on the decision issued by the Romanian Academy.

Article 25.
Employment in positions corresponding to the functions and professional grades of RDI staff is carried out according to the principle of professional merit, based on transparent and fair procedures that respect the general principles and conditions provided by the European Charter for Researchers.

Article 26.
The equivalence of university teaching functions with the functions and professional RDI grades within ICBP-NS applies only with the approval of the Scientific Council, after the evaluation of the additional standards adopted at ICBP-NS.

Article 27.
The personal data of individuals involved in the examination process are processed within the information platform, in compliance with the provisions of Regulation (EU) 2016/679 on the protection of natural persons with regard to the processing of personal data and on the free movement of such data, and repealing Directive 95/46/EC (General Data Protection Regulation).

Article 28.
A summary report on the organization and conduct of the promotion examination is prepared at the level of ICBP-NS by the human resources officer and submitted annually, within 15 calendar days from the end of the calendar year for which the reporting is made, both in physical format with a forwarding address, to the Research and Doctoral Programs Service, and in electronic format to the email address bpg@acad.ro.

Article 29.
Annexes DP, L, 1P–5P, 1E, and 2E form part of this Regulation and, together with it, were established and drawn up by ICBP-NS in accordance with the regulations and models proposed by the Romanian Academy in the Methodological Norms on organizing the promotion examination for obtaining professional grades of RDI staff in institutes of the Romanian Academy / July 15, 2025.

The present Regulation was approved in the meeting of the Scientific Council of ICBP-NS on August 7, 2025. It may be adjusted based on the calibration provided by the examinations for each category (scientific degree) that will take place subsequently.

Director,

Acad. Maya Simionescu

Annex SC

Minimum Standards of the "Nicolae Simionescu" Institute of Cellular Biology and Pathology for the Award of Professional Grades

The filling of research, development, and innovation (RDI) positions within the "Nicolae Simionescu" Institute of Cellular Biology and Pathology (ICBP-NS) is carried out either through a competition organized for a vacant position, or through an examination for promotion to a higher professional grade than the one currently held.

In order to participate in the competitions organized by ICBP-NS for filling vacant RDI positions, candidates must mandatorily meet the legal minimum standards (according to Law 183/2024 and the Minister's Order no. 6129/2016 on the status of RDI personnel), as well as the additional internal standards established and approved by the Scientific Council of ICBP-NS.

For promotion, only scientific researchers (CS, CSIII, and CSII) with permanent employment contracts who exceed by at least 50% at least two-thirds of ICBP-NS's own minimum standards may take the examination for promotion to a higher professional grade within ICBP-NS. Promotion is carried out through the conclusion of an addendum to the existing employment contract.

1. Minimum ICBP-NS Standards for Awarding the Professional Grade of CSI

Scientific Researchers **CSII**, who have permanent employment contracts, may take the exam for promotion to a higher professional grade within ICBP-NS, provided that they meet the following criteria:

- fulfill all 4 minimum standards under Criteria 1–4;
- exceed by at least 50% at least three of these four minimum standards.

Promotion is carried out through an addendum to the existing employment contract.

Criterion 1. Scientific articles published after the PhD, as main author

Minimum standard: The candidate must have published, after obtaining the PhD title, at least **4 articles** in ISI-indexed journals, with a cumulative AIS* of at least 4, where the candidate appears as main author (first author, corresponding author, or last author, as applicable).

For promotion (≥50% above standard): At least 6 ISI-indexed articles, with a cumulative AIS* ≥ 6, where the candidate is main author.

Criterion 2. Scientific articles published in the last 5 years, as main author

Minimum standard: The candidate must have published, in the last 5 years, at least 2 articles in ISI-indexed journals – each article with an AIS* of at least 0.5 – in which the candidate appears as main author (first author, corresponding author, or last author, as applicable).

For promotion (exceeding the standard by at least 50%): The candidate must have published, in the last 5 years, at least 3 articles in ISI-indexed journals – each article with an AIS* of at least

0.5 – in which the candidate appears as main author (first author, corresponding author, or last author, as applicable).

***Note:*

-AIS (Article Influence Score), according to https://jcr.clarivate.com/ for the year of publication; for articles published before 2007, the AIS value from 2007 will be used. If the classification for the year of publication is not available, the most recent available classification will be considered.

-The AIS value for mandatory preliminary conditions is divided according to the formula: AIS/pi**,** where *pi* = 1 when the article has 1, 2, or 3 main authors (defined as first, last, and corresponding), or equals the number of main authors when there are more than 3.

-At least 50% of published scientific articles must be listed in Web of Science under the category *"document type: article"*. This percentage does not include works classified as *"review"* or multiple combinations such as *"Article; Proceedings Paper"*, *"Article; Book Chapter"*, etc

Criterion 3. Coordination of research projects/grants obtained after the PhD

Minimum standard: The candidate must have coordinated, after obtaining the PhD degree, at least two research projects/grants, national or international, in one of the following variants:

• two projects (national or international), as Project Director or Partner Coordinator, or

• one national project and one international project (as Director or National Coordinator).

Note: For at least one of these projects, the coordinated research team must include a minimum of 3 members**.**

For promotion (exceeding the standard by at least 50%): The candidate must have coordinated, after obtaining the PhD degree, at least three research****** projects/grants, national or international, in one of the following variants:
• 3 research projects/grants (national or international), as Project Director or Partner Coordinator, or
• 2 national projects and 1 international project (as Director or National Coordinator), or
• 1 national project and 2 international projects (as Director or National Coordinator).

Note: For at least one of these projects, the coordinated research team must include a minimum of 3 members**.**

******Note:

-Projects must be obtained either: (1)through national or international competition (in which case a link to the competition page or other documents proving the competition must be provided), or through non-competitive allocation, provided the project budget is at least **€50,000**.

-Projects that do not include logistics expenses, grants funded by the candidate's own institution, or grants for congress participation will not be considered.

-Projects must be carried out in an institution with research and development activities.

Criterion 4. Quantification of Scientific Activity

Minimum standard: Total score obtained based on the calculation of indicators from Table 1: **500 points Σ1–2** and **600 points Σ1–18**.

For promotion (exceeding the standard by at least 50%): Total score obtained based on the calculation of indicators from Table 1: **750 points Σ1–2** and **900 points Σ1–18**.

Table 1 – Parameters Considered and their Quantification

No.	Parameter	Calculation Method	*Score*
1.	Articles in WoS-indexed journals, as main author	according to the formula (1)	
2.	Articles in WoS-indexed journals, as co-author	according to the formula (2)	
3.	Articles in BDI-indexed journals, as main author	(1+C_1)+(1+C_2)+... (1+C_n)	
4.	Articles in BDI-indexed journals, as co-author	0.7 x [(1+C_1)+(1+C_2)+... (1+c_n)]	
5.	Books with prestigious international publishers	(100+c):n	
6.	Books with other international publishers	(40+c):n	
7.	Books with the Romanian Academy or University presses	(20+c):n	
8.	Books with other national publishers	(10+c): n	
9.	Chapters in prestigious international publishers	(50+c):n	
10.	Chapters in volumes with other international publishers	(20+c): n	
11.	Chapters in volumes published by the Academy Publishing House or University presses	(10+c): n	
12.	Chapters in books/volumes with national publishers	(5+c):n	
13.	Editor/Redactor/Coordinator of books with prestigious international publishers	(50+c):n	
14.	Editor/Redactor/Coordinator of books with other international publishers	(30+c):n	
15.	Editor/Redactor/Coordinator of books with national publishers	(20+c): n	
16.	Editor (including guest editor) of WoS-indexed journals	5 X (AIS_1+AIS_2+ ... AIS_n)	
17.	Research projects/grants won through competition	1 point for every 10,000 euros obtained as project director or partner coordinator	
18.	Constant and sustained involvement in	2 points per event	

	scientific activities organized within the institute, including active participation in seminars, workshops, and other internal scientific events (discussions, questions, or feedback provided to colleagues during these events)		

Formula (1):1 x [4+(7xAIS_1)+c1] + 1 x [4+(7xAIS_2)+c2] + ... + 1 x [4+(7XAIS_N)+C_N]
Formula (2):0.7 x [4+(7xAIS_1)+c_1] + 0.7 x [4+(7xAIS_2)+c_2] + ... + 0.7 x [4+(7XAIS_N)+C_N]AIS_1, AIS_2 ..., AIS_N is the factor AIS (*Article Influence Score*), according to *Journal Citation Reports* (published by Clarivate) for the year of publication. For articles published before 2007, the AIS value from 2007 will be used. If the classification for the publication year is not available, the most recent available classification will be considered.
c_1, c_2 ... c_n number of citations (excluding self-citations) for article 1, 2 … N, taken from Web of Science or Scopus at the time of preparing the application file, with the source specified.
c - citations (excluding self-citations) taken from Web of Science or Scopus at the time of submitting the file, with the source specified. A self-citation is considered when the evaluated author cites a previous work in which they were an author.
N - total number of articles in the respective category (excluding abstracts, reviews, obituaries, notes, editorials, corrections, errata).
n - number of authors (editors, redactors, coordinators for the books/chapters edited/prepared).

Parameter	Total score resulting from the calculation of the indicators in Table 1/promotion
Σ_1-2 (international recognition)	Minimum standard: **500 points**. For promotion: **750 points**.
Σ_1-18 (total performance)	Minimum standard: **600 points**. For promotion: **900 points**.

2. ICBP-NS Minimum Standards for the Award of the Professional Grade of CSII

Researchers holding the title of Scientific Researcher III (CS III), with an individual employment contract of indefinite duration, may apply for promotion to a higher professional grade within ICBP-NS, provided that they meet the following criteria:

- they meet all three minimum standards set out in Criteria 1–3;
- they exceed by at least 50% at least two of the three minimum standards.

Promotion is carried out by signing an addendum to the existing individual employment contract.

Criterion 1. Scientific Articles Published after PhD, as Main Author

Minimum standard: The candidate must have published, after obtaining the PhD degree, at least 2 scientific articles in ISI-indexed journals, as main author, which must meet the following conditions:

- The cumulative AIS***** of the two articles must be at least 2.
- At least one article must have been published in the last 5 years, with an *AIS of at least 0.4**.

For promotion (exceeding the minimum standard by at least 50%): The candidate must have published, after obtaining the PhD degree, as main author:

- At least 3 articles in ISI-indexed journals, with a *cumulative AIS* of at least 3**;
- At least 2 articles must have been published in the last 5 years, each with an *AIS* of at least 0.4**.

*****Note:

-The AIS (Article Influence Score), according to https://jcr.clarivate.com/ from the year of publication; for articles published before 2007, the AIS value from 2007 will be used. If the classification from the year of publication is not available, the most recent available classification will be considered.

-The AIS value for the mandatory preliminary conditions is divided according to the formula: AIS/pi, where pi = 1 when the article has 1, 2, or 3 main authors (first, corresponding, and last author), or equals the number of main authors if there are more than 3.

-At least 50% of the published scientific articles must be indexed in Web of Science with the classification "document type: article." This percentage does not include works classified as "document type: review" or multiple combinations such as: "Article; Proceedings Paper," "Article; Book Chapter," etc.

Criterion 2. Coordination of Research Projects/Grants Obtained after PhD**

Minimum standard: After obtaining the PhD degree, the candidate must have coordinated at least one research project or grant (national or international) as project director or partner responsible.

For promotion (exceeding the minimum standard by at least 50%): The candidate must have coordinated at least two research projects or grants (national or international as project director or partner responsible).

Note: For at least one of the coordinated projects, the research team must include a minimum of 3 members**.**

**Note:

-Projects must be obtained: (1)through national or international competition, the link to the competition webpage or other documents proving the competition must be provided, (2)through direct award, non-competitive, in which case the project budget must be equivalent to at least €50,000**.**

-Projects without logistical expenses, grants financed by the candidate's own institution, or grants for congress participation will not be considered.

-Projects must be carried out within an institution conducting research and development activities.

Criterion 3. Quantification of Scientific Activity

Minimum standard: Total score obtained based on the calculation of the indicators in Table 1:**300 points Σ1–2** and **450 points Σ1–18**

For promotion (exceeding the minimum standard by at least 50%): Total score obtained based on the calculation of the indicators in Table 1: **450 points Σ1–2** and **675 points Σ1–18**

1. Parameters Taken into Account and their Quantification Method

No.	*Parameter*	Calculation Method	*Score*
1.	Articles in WoS-indexed journals, as main author	according to the formula (1)	
2.	Articles in WoS-indexed journals, as co-author	according to the formula (2)	
3.	Articles in BDI-indexed journals, as main author	(1+C_1)+(1+C_2)+... (1+C_n)	
4.	Articles in BDI-indexed journals, as co-author	0.7 x [(1+C_1)+(1+C_2)+... (1+c_n)]	
5.	Books at prestigious international publishers	(100+c):n	
6.	Books at other international publishers	(40+c):n	
7.	Books at the Romanian Academy Publishing House or university presses	(20+c):n	
8.	Books at other national publishers	(10+c): n	
9.	Book chapters at prestigious international publishers	(50+c):n	
10.	Book chapters at other international publishers	(20+c): n	
11.	Book chapters at the Romanian Academy Publishing House or university presses	(10+c): n	
12.	Book chapters in volumes at national publishers	(5+c):n	
13.	Editor/redactor/coordinator of books at prestigious international publishers	(50+c):n	

14.	Editor/redactor/coordinator of books at other international publishers	(30+c):n	
15.	Editor/redactor/coordinator of books at national publishers	(20+c): n	
16.	Editor (including guest editor) of WoS-indexed journals	5 X (AIS_1+AIS_2+ ... AIS_n)	
17.	Research projects/grants won through competition	1 point for every €10,000 attracted as project director or partner coordinator	
18.	Constant and sustained involvement in scientific activities organized within the institute, including active participation in seminars, workshops, and other internal scientific events (discussions, questions, or feedback offered to colleagues during these events).	2 points per event	

Formula (1):1 x [4+(7xAIS_1)+c1] + 1 x [4+(7xAIS_2)+c2] + ... + 1 x [4+(7XAIS_N)+C_N]

Formula (2):0.7 x [4+(7xAIS_1)+c_1] + 0.7 x [4+(7xAIS_2)+c_2] + ... + 0.7 x [4+(7XAIS_N)+C_N]AIS_1, AIS_2 ..., AIS_N AIS is the Article Influence Score, according to the *Journal Citation Reports* (published by Clarivate) from the year of publication. For articles published before 2007, the AIS value from 2007 shall be used. If the classification from the year of publication is not available, the most recent available classification shall be considered.

c_1, c_2 ... c_n – the number of citations without self-citations for article 1, 2 …, N, retrieved from Web of Science or Scopus at the time of preparing the file, with specification of the source used.

c – citations without self-citations retrieved from Web of Science or Scopus at the time of submission of the file, with specification of the source used. Self-citation is considered to be the situation in which the evaluated author cites a previous work in which he/she was an author.

N – the total number of articles in the respective category (excluding abstracts, reviews, commemorations, notes, editorials, corrections, errata).

n – the number of authors (editors, reviewers, coordinators for the books/chapters edited or prepared).

Parameter	Total score resulting from the calculation of the indicators in Table 1/promotion
Σ_1-2 (international recognition)	Minimum standard: **300 points**. For promotion: **450 points**.
Σ_1-18 (total performance)	Minimum standard: **450 points**. For promotion: **675 points**.

3. ICBP-NS Minimum Standards for Awarding the Professional Title of CSIII

Scientific Researchers (CS) with an indefinite-term individual employment contract may take the examination for promotion to a higher professional grade within ICBP-NS, provided they meet the following criteria:

- they must fulfill all three minimum standards specified under Criteria 1–3;
- they must exceed by at least 50% at least two of the three minimum standards.

Criterion 1. Scientific articles published

Minimum standard: The candidate must have published at least 5 scientific articles in ISI-indexed journals, either as principal author or co-author.

For promotion (by exceeding the minimum standard by at least 50%): At least 8 ISI-indexed articles must be published, as principal author or co-author.

Criterion 2. Scientific articles published with a cumulative AIS of at least 2

Minimum standard: The candidate must have published **at least 2 articles** in ISI-indexed journals, with a cumulative AIS* of at least 2.

For promotion (by exceeding the minimum standard by at least 50%): The candidate must have published at least 3 articles in ISI-indexed journals, with a cumulative AIS* of at least 3.

**Note:*

-The AIS (Article Influence Score) factor is taken from https://jcr.clarivate.com/ for the year of publication. For articles published prior to 2007, the 2007 AIS value shall be used. If the classification for the publication year is not available, the most recent available classification will be taken into consideration.

-The AIS value for mandatory preliminary conditions is fractionalized according to the formula: AIS/pi, where pi = 1 if the article has 1, 2, or 3 principal authors (namely the first author, the last author, and the corresponding author), or equals the number of principal authors if there are more than 3.

-At least 50% of the scientific articles published must be listed in Web of Science under the "document type": "article". This percentage does not include works categorized as "document type": "review" or multiple combinations such as "Article; Proceedings Paper", "Article; Book Chapter", etc.

Criterion 3. Quantification of scientific performance

Minimum standard: Total score resulting from the calculation of the indicators in Table 1: **100** points Σ_1-2 and **150** points Σ_1-17.

For promotion (by exceeding the minimum standard by at least 50%): Total score resulting from the calculation of the indicators in Table 1: **150** points Σ_1-2 and **225** points Σ_1-17.

Table 1. Parameters taken into account and their method of quantification

No.	*Parameter*	Calculation Method	*Score*
1.	Articles in WoS-indexed journals, as main author	according to the formula (1)	
2.	Articles in WoS-indexed journals, as co-author	according to the formula (2)	
3.	Articles in BDI-indexed journals, as main author	(1+C_1)+(1+C_2)+... (1+C_n)	
4.	Articles in BDI-indexed journals, as co-author	0.7 x [(1+C_1)+(1+C_2)+... (1+c_n)]	
5.	Books published by prestigious international publishers	(100+c):n	
6.	Books published by other international publishers	(40+c):n	
7.	Books published by the Romanian Academy Publishing House or by University presses	(20+c):n	
8.	Books published by other national publishers	(10+c): n	
9.	Chapters in volumes published by prestigious international publishers	(50+c):n	
10.	Chapters in volumes published by other international publishers	(20+c): n	
11.	Chapters in volumes published by the Romanian Academy Publishing House or University presses	(10+c): n	
12.	Chapters in books/volumes published by national publishers	(5+c):n	
13.	Editor/redactor/coordinator of books published by prestigious international publishers	(50+c):n	
14.	Editor/redactor/coordinator of books published by other international publishers	(30+c):n	
15.	Editor/redactor/coordinator of books published by national publishers	(20+c): n	
16.	Editor (including guest editor) of WoS-indexed journals	5 X (AIS_1+AIS_2+ ... AIS_n)	
17.	Consistent and sustained involvement in scientific activities organized within the institute, including active participation in seminars, workshops, and other internal scientific events (discussions, questions, or feedback offered to colleagues during these events).	2 points per event	

Formula (1):1 x [4+(7xAIS_1)+c1] + 1 x [4+(7xAIS_2)+c2] + ... + 1 x [4+(7XAIS_N)+C_N]
Formula (2):0.7 x [4+(7xAIS_1)+c_1] + 0.7 x [4+(7xAIS_2)+c_2] + ... + 0.7 x [4+(7XAIS_N)+C_N]AIS_1, AIS_2 ..., AIS_N **AIS** is the *Article Influence Score*, according to the Journal Citation Reports (published by Clarivate) for the year of publication. For articles published before 2007, the 2007 AIS value shall be used. If the classification for the year of publication is unavailable, the most recent available classification shall be considered.
c_1, c_2 ... c_n — the number of citations excluding self-citations for article 1, 2 …, N, retrieved from Web of Science or Scopus at the time of preparing the file, with the source specified.
c — citations excluding self-citations, retrieved from Web of Science or Scopus at the time of submitting the file, with the source specified. A self-citation is considered to be the situation in which the evaluated author cites a previous work in which they were an author.
N — the total number of articles in the respective category (excluding abstracts, reviews, commemorations, notes, editorials, corrections, errata).
n — the number of authors (editors, redactors, coordinators for the books/chapters edited or prepared).

Parameter	Total score resulting from the calculation of the indicators in Table 1/promotion
Σ_1-2 (international recognition)	Minimum standard: **100 points**. For promotion: **150 points**.
Σ_1-17 (total performance)	Minimum standard: **150 points**. For promotion: **225 points**.

4. Minimum Standards for Awarding the Professional Grade of CS

Minimum criteria for participation in the CS competition:

1. **Graduate with a bachelor's or diploma degree** from long-term higher education studies, or holder of a master's degree in the specialty or related fields (competition requirement only);
2. **Status of PhD candidate or PhD** holder in the specialty of the position's discipline or in a related field (competition requirement only);
3. At least two **letters of recommendation** from supervisors and/or course professors (competition requirement only);
4. **One scientific article published** in an ISI-indexed journal as co-author in position 2 or 3, or in a BDI-indexed journal as first author (competition requirement only).

5. Minimum Standards for Awarding the Professional Grades of ACS

Minimum criteria for participation in the ACS competition:

1. Graduate with a **bachelor's or diploma degree** from long-term higher education studies, or holder of a master's degree in the specialty or related fields (competition requirement only);

2. At least two **letters of recommendation** from supervisors and/or course professors (competition requirement only).

Approved at the meeting of the Scientific Council of ICBP-NS on 07.08.2025

Director ICBP N. Simionescu **26.06.2025**

Acad. Maya Simionescu

Documents Used for Drafting and Developing this Regulation:

Ministerial Orders no. 6129/2016 and 3019/2025 regarding the approval of minimum standards (for awarding the professional grades of Scientific Researcher II and Scientific Researcher I); Government Decisions no. 1568/2024 and 1569/2024;Methodological Norms approved by the Bureau of the Presidium of the Romanian Academy, regarding the organization of the promotion examination for obtaining a professional grade by CDI personnel / July 2025; Methodology for verification and evaluation of the files containing the documents related to the competition, respectively the examination, for awarding the professional grades of CSII and CSI; Law no. 183/2024 on the status of CDI personnel.

Annexes useful for preparing the application file for registration in the promotion exam (candidate):

Annex DP: Documents required for registration (application file) for the promotion exam and the List of documents included in the exam file for obtaining the professional grades of CSII and CSI (according to **ANNEX 1 to the Methodology**, Methodological Norms on organizing the promotion exam for obtaining professional CDI grades in AR institutes);

Annex L: Procedural steps for creating links to the supporting/justifying documents from the index (according to **ANNEX 3 to the Methodology**, Methodological Norms on organizing the promotion exam for obtaining professional CDI grades in AR institutes);

Annex 1P: Application form for registration to the exam – model (according to **ANNEX 5 to the List**, Methodological Norms on organizing the promotion exam for obtaining professional CDI grades in AR institutes);

Annex 2P: Exam file cover – model (according to **ANNEX 1 to the List**, Methodological Norms on organizing the promotion exam for obtaining professional CDI grades in AR institutes);

Annex 3P: Candidate's statement on own responsibility – model (according to **ANNEX 3 to the List**, Methodological Norms on organizing the promotion exam for obtaining professional CDI grades in AR institutes);

Annex 4P: Consent statement regarding the processing of personal data, in accordance with Regulation (EU) 2016/679 – model (according to **ANNEX 4 to the List**, Methodological Norms on organizing the promotion exam for obtaining professional CDI grades in AR institutes);

Annex 5P: Verification sheet for meeting the specific standards of the position/professional grade.

Annexes useful for the evaluation process of the files (committees, ICBP-NS):

Annex 1E: Evaluator's declaration – model (according to **ANNEX 2 to the Methodology**, Methodological Norms on organizing the promotion exam for obtaining professional CDI grades in AR institutes);

Annex 2E: Evaluation report (committee member) – model (according to **ANNEX 3 to the List**, Methodological Norms on organizing the promotion exam for obtaining professional CDI grades in AR institutes).

Annex DP

Documents required for registration in the promotion exam

a. application form for registration in the exam, to which is attached a sworn statement regarding the accuracy of the information presented in the file, completed and signed in original by the candidate (Annex 1P and Annex 3P);
a. curriculum Vitae in EUROPASS format signed by the candidate (Annex 3), which must mandatorily include:
i. completed studies and diplomas obtained;
ii. professional experience and relevant previous positions held;
iii. research, development, and innovation projects led as project director and the grants obtained, if applicable, specifying for each the source of funding, the funding volume, and the main resulting publications or invention patents;
iv. awards or other elements of recognition of scientific contributions;
v. a narrative description of the 3 most important achievements since the last promotion – maximum 3 pages;

b. list of publications, works, articles/studies, patents of invention selected by the candidate according to their relevance to the candidate's scientific research activities, signed in original by the candidate (Annex 4). The list must mandatorily include:
i. a list of up to 10 most relevant scientific publications, such as authored books, articles/studies/chapters, edited volumes, works;
ii. the list of invention patents and other industrial property titles;
iii. the list of authored books and edited/published volumes;
iv. the list of full-text articles/studies published in journals from the main international scientific stream;
v. the list of other scientific works and contributions;

c. verification sheet of compliance with the organization's own standards, completed and signed by the candidate (Annex 5P);
d. copy of the identity document or any other document that certifies identity, as provided by law, certified by the candidate as conforming to the original, with full name and signature;
e. copy of the marriage certificate or proof of name change, if applicable, certified by the candidate as conforming to the original, with full name and signature;
f. Medical certificate attesting appropriate health status, issued by the candidate's family physician or by authorized medical institutions no more than 3 months prior to the exam;
g. Signed consent statement for the processing of personal data (Annex 4P);
h. Criminal record certificate;
i. Copy of the PhD diploma; if the diploma was not issued by a higher education institution in Romania, a copy of the recognition or equivalence certificate must be submitted, certified by the candidate as conforming to the original, with full name and signature;
j. Sworn statement declaring that, in the last 3 years prior to registering for the promotion exam, the candidate has not been sanctioned for committing a serious breach of good conduct in CDI activity as provided by art. 52 para. (8) of Law no. 183/2024, completed and signed by the candidate (Annex 3P).

The documents must be submitted both in physical format and in electronic format (each document from the physical file will be scanned according to the index and saved on a memory stick) at the ICBP-NS headquarters, as well as sent to the e-mail address indicated in the announcement.

The exam file for the position of CSII or CSI consists of two parts:
a) administrative file **–** includes the documents listed under points a–j and the documents issued during the course of the exam. All documents are registered, each document is assigned a link (according to the procedural steps set out in Annex L), indexed and numbered, then scanned in the order listed in the *"List of documents included in the competition/exam file"* provided in Annex DP;
b) scientific works portfolio – the works are scanned in PDF format, each document is assigned a link, then numbered and indexed.

LIST
of the documents included in the exam file for obtaining the professional research-development grades of CSII and CSI

The documents listed below must be filed in electronic format (PDF)**,** as separate files, attached in the order indicated in the index. Documents must be numbered according to the index.

The exam file is submitted only in complete form, containing all documents required for the position the candidate applies for, in the order indicated below. The introduction of false information or non-compliant documents in the exam file is sanctioned under legal provisions.

The standard cover form must be completed by the candidate, according to Annex 2P.

Each exam file for the awarding of the professional grades CSII and CSI will include the following documents:

A. Administrative File

1. Cover letter for each file from the management of the research institutes/research centers/branches of the Romanian Academy to the Romanian Academy, containing: candidate's full name, current scientific grade, the organization to which the candidate belongs or which organizes the exam, the scientific grade applied for, the targeted field of the position – specialty commission – fundamental and associated field, number of file pages, registration number, and contact details of the issuing person/institution for details/information and for transmission of evaluation results.
2. Index of the documents in the file, indicating the page where each document is found, with links attached, according to Annex L.
3. Report presenting the exam, approved by the management of the organizing institution, including:

   -the stages of the exam shall be presented – from the publication of the exam announcement (date of announcement, where it was published), the decision appointing the exam commission and the appeals commission, the evaluation results, up to the validation of the results in the scientific council.

   -the field and the Scientific Section of the Romanian Academy responsible for evaluating the candidate's file shall be indicated.

   -reference shall be made to the institution's website containing the exam regulations for CSI and CSII positions/grades, as approved by the management of the organizing institution.

4. Extract from the minutes of the scientific council meeting – date, members present, approval of exam results.
5. Extract from the scientific council meeting regarding approval of organizing the promotion exam for institutes/research centers of the Romanian Academy. For Academy Branches: approval of the Branch President/Branch Executive Board, following the scientific council's endorsement of proposals from subordinate institutes.
6. Report of the exam commission, drafted in compliance with legal provisions, including all stages of the promotion exam.
7. Assessment reports of the members of the promotion exam commission for obtaining the CSII or CSI grade (Annex 2E) and sworn statement (Annex 1E). Both documents must be signed, dated, and registered at the ICBP-NS secretariat.
8. Decision appointing the exam and appeals commissions, indicating function, university or research grade, full name, and workplace of each member.
9. Application for registration in the exam, registered, signed, and dated by the candidate, approved by the head of the research and innovation organization, and endorsed by its legal department (Annex 1P).
10. Verification sheet of compliance with the standards specific to the position/grade applied for, completed and signed by the candidate and endorsed by the research organization, in line with legal provisions. Only published works (with volume, number, pages, and/or DOI) are considered. The sheet must be structured to allow verification, with parallel columns showing the minimal standards required and the candidate's results (Annex 5P).
11. Career development proposal regarding scientific research activities, maximum 5 pages.
12. Statement of responsibility, handwritten and signed by the candidate, including identification data, declaring that the data in the file refer to their own activities and results. The candidate accepts responsibility for any false statements, and for ensuring the originality of the scientific portfolio and compliance with quality and professional ethics standards (Annex 3P).
13. Consent form for the processing of personal data, according to Regulation (EU) 2016/679 (Annex 4P).
14. Curriculum Vitae in EUROPASS format (PDF), dated and signed by the candidate.
15. Information on awards or other forms of recognition of the candidate's scientific contributions.
16. Proof of studies – copies of degree diplomas (Bachelor's, Master's, PhD, as applicable), certified "true to the original." If the candidate does not hold a diploma issued by a Romanian higher education institution, they must submit a certified copy of the recognition/equivalence certificate before employment and contract signing, otherwise the appointment act will not be issued.
17. Proof of identity:
    a) copy of birth certificate;
    b) if applicable, copy of the document certifying name change (marriage certificate or proof of change);
    c) copy of ID card or another legal identity document.
18. Criminal record certificate.
19. Medical certificate issued by the candidate's family doctor.
20. Copy of the promotion exam announcement, posted at the institution's headquarters and on the organizing institution's website.

B. Portfolio of Scientific Works

The list of scientific publications (grouped by category), works, articles/studies, patents considered relevant by the candidate for the applied position, for their own research activities, and for research projects (contract/grant-based), including citations.

The list is structured as follows:
a) doctoral thesis (or theses);
b) list of the 10 most relevant scientific publications (books, articles/studies/chapters, edited volumes);
c) list of invention patents and other industrial property titles;
d) list of authored books and edited/published volumes;
e) list of full-length articles/studies published in mainstream international scientific journals;
f) list of other scientific works and contributions (or, where applicable, in the field of artistic creation or national defense);
g) research-development-innovation projects (contract/grant-based);
h) other works.

NOTE:

All documents in the file must be registered at the secretariat of the organizing unit. For all copies, the phrase “certified true to the original” must be written, signed, and dated.

Annex L

Procedural steps for creating hyperlinks to the supporting/justifying documents listed in the index (opis):

A. Initial copying of the index (opis) and documents onto a USB drive

B. To assign a hyperlink to each document listed in the index, proceed as follows:

1. Select the text to which you wish to add the hyperlink.
2. In the *Insert* menu → click the *Link* icon [or press the keys Ctrl + K simultaneously].
3. In the *Insert Hyperlink* window, select (by clicking) the document to which you want to create the link.
4. Click *OK*.
5. After inserting the hyperlink, check the connection by pressing Ctrl and simultaneously clicking (Ctrl+Click).

After saving the document as a PDF, the hyperlinks should be functional.
Once all hyperlinks are finalized, verify their functionality.

No...../.....

Approval

Director of ICBP-NS,

APPLICATION FOR REGISTRATION TO THE EXAMINATION

Madam Director,

The undersigned, ..., graduate of ....., appointed to the position of ..... at the "Nicolae Simionescu" Institute of Cellular Biology and Pathology, e-mail address ....., mobile phone number ....., respectfully request approval for my registration in the examination for promotion to the professional grade of Research Scientist ....., full-time, on an indefinite basis, within the Department of ..... of the ..... Institute, specialization ....., subfield ..... .

I hereby state that I hold a doctoral degree and have professional seniority of ..... years in the field.

The announcement regarding the competition was published on ..... (date and location)..... (only if applicable).

DECLARATION OF CONSENT
regarding the processing of personal data, pursuant to Regulation (EU) 2016/679

I, the undersigned, ..., residing in ....., born on ..... in the locality of ....., county of ....., holder of ID card series ... no. ....., issued on ..... by ....., with Personal Numeric Code (CNP) ....., as a participant in the promotion examination held on ..... at ....., organized by the Institute of Cellular Biology and Pathology "Nicolae Simionescu", hereby declare that I consent to the use and processing of my personal data by the staff designated by the Ministry, including the communication of such data, if necessary, to other entities (the National Commission for the Certification of Titles, Diplomas and University Certificates, the Consultative College for Research, Development and Innovation, etc.).

I have been informed of the provisions of Regulation (EU) 2016/679 on the protection of natural persons with regard to the processing of personal data and on the free movement of such data, repealing Directive 95/46/EC (General Data Protection Regulation), adopted by the European Parliament and the Council of the European Union, namely:
— the right of access, under which the person has the right to obtain confirmation from the National Authority for Research (ANC) as to whether or not personal data are being processed, and, if so, to obtain access to such data and to information regarding the way they are processed;
— the right to data portability, i.e., the right to receive personal data in a structured, commonly used format, and the right to have such data transmitted directly to another controller, where technically feasible;
— the right to object, meaning the right of the person to oppose the processing of personal data;
— the right to rectification, meaning the correction, without undue delay, of inaccurate personal data;
— the right to erasure of data ("right to be forgotten"), meaning the right of the person to request that their personal data be erased without undue delay, where one of the following grounds applies: the data are no longer necessary for the purposes for which they were collected or processed; the person withdraws consent and there is no other legal basis for processing;
— the right to restriction of processing, which may be exercised where the person contests the accuracy of the data, for a period enabling the institution to verify their correctness; or where the processing is unlawful, and the person opposes the erasure of the data, requesting instead the restriction of their use.

I acknowledge that my refusal to provide the personal data requested by the ANC will make it impossible to establish the legal relations necessary for the promotion process and that the above-mentioned institution cannot be held liable in this regard.

If the personal data provided are incorrect or subsequently change (change of residence, civil status, e-mail address, etc.), I undertake to inform the ANC in writing, in due time.

I have also been informed that such data will be treated confidentially, in accordance with the provisions of Regulation (EU) 2016/679 of the European Parliament and of the Council of 27 April 2016 on the protection of natural persons with regard to the processing of personal data.

REGULATIONS

regarding the organization of the competition for filling vacant research staff positions within the Institute of Biology and Pathology "Nicolae Simionescu" Cellular of the Romanian Academy

-Edition 1, Revision 1-

Chapter I. General provisions

Article 1. This Regulation establishes the methodology for filling vacant research positions, differentiated by professional grade, for personnel involved in research, development and innovation (RDI) activities, within the "Nicolae Simionescu" Institute of Cellular Biology and Pathology (IBPC-NS) of the Romanian Academy.

Article 2. Vacant positions are filled through a competition organized in accordance with the provisions of Law 53/2003 on the Labor Code, Law 183/2024 on the Status of RDI personnel, Order of the Ministry of National Education and Scientific Research No. 6129/20.12.2016, Methodological Norms on the organization of competitions for filling vacant RDI personnel positions issued by the Romanian Academy on July 15, 2025 and in accordance with this regulation approved at the IBPC-NS level, approved by the Biological Sciences Section and published on the institute's website.

Article 3. The Regulation applies to all persons who wish to occupy in IBPC-NS, for a fixed or indefinite period, one of the following research and development positions and professional ranks, defined according to Law 183/2024 and maintaining the equivalence with the professional ranks provided for in the European Charter for Researchers, as follows:

(i) scientific researcher grade I (CSI), equivalent to senior principal researcher R4, holding doctorate;
(ii) scientific researcher level II (CSII), equivalent to senior researcher R3, holding doctorate;
(iii) scientific researcher level III (CSIII), equivalent to recognized researcher R2, holding doctorate;
(iv) scientific researcher (CS), equivalent to the R1 beginner researcher, holding a doctorate or having the status of a doctoral student;
(v) scientific research assistant (ACS), equivalent to a licensed scientific research assistant.

Article 4. The recruitment of RDI personnel to positions is carried out through a competition, organized on the basis of the following principles:

a. the principle of transparency, competence, gender equality, non-discrimination and equal and fair access to filling vacant positions;
b. the principle of ensuring the quality and professional training of research staff;
c. correct and complete information regarding the organization and conduct of the competitions;
d. transparency regarding administrative, financial and evaluation information of research positions according to the legislation in force.

Article 5.

(1) Employment in vacant research positions with an individual employment contract, for an indefinite or fixed period, is possible only for the candidate declared the winner following the organized competition.

(2) Employment for participation in research projects, projects in the field of education and vocational training or in any other types of projects, regardless of the funding source, may be made for a fixed period, at most equal to the duration of the respective project, without going through other prior formalities and/or selection processes, for the staff nominated in the staff lists, corresponding to the rank held, as members of the project team, as well as for the staff of the research organization. In the case of staff from IBPC-NS, employment within a project is carried out based on the decision of the Director, by concluding an individual employment contract. The salary is granted within the limit of the available funds, according to the provisions of the funding contract/funder's rules. IBPC-NS may refuse to conclude an individual employment contract, as the case may be, with persons from outside the institution who have been nominated, without the prior consent of the research organization, in the personnel lists, as members of a research project team, a project team in the field of education and vocational training or any other type of project team.

(3) All persons who do not hold the professional degree in research and development corresponding to the position for which they are applying and who meet the own standards established by IBPC-NS may participate in the competition for a vacant research position. Also, all persons who hold the professional degree in research and development corresponding to the position for which they are applying and who meet the additional standards specific to IBPC-NS may participate, whether or not they are already included in the national R&D system, without any discrimination, under the conditions of the law.
The filling of research positions, through competition, by research, development and innovation staff, hereinafter referred to as RDI staff, is the responsibility of IBPC-NS in compliance with these methodological rules, as well as the general principles and conditions provided for by the European Charter for Researchers.

Chapter II. Minimum training requirements

Article 6. IBPC-NS organizes a competition to fill one or more CDI positions only if they are vacant and based on a substantiation note proposing to put the position up for competition.

Article 7. Only graduates of accredited higher education institutions, who have long-term higher education, graduated with a bachelor's degree or equivalent, or equivalent higher education (bachelor's and master's studies according to Law 288/2004) and who meet the provisions of Law no. 183/2024 regarding the necessary conditions for registration, para. (10-11), the minimum standards specific to each scientific field, para. (1), but also the additional standards established and approved within the IBPC-NS of the Romanian Academy (according to Annex SC.C) may register for the competition.

Article 8. Only persons who meet the following general conditions may participate in the contest:

a. have Romanian citizenship, citizenship of other European Union member states or of the states belonging to the European Economic Area and domiciled/residing in Romania;
b. have the minimum age regulated by legal provisions;
c. have full capacity to exercise;
d. have a state of health appropriate to the position for which they are applying, certified on the basis of a medical certificate issued by the family doctor or by the authorized health units;
e. meet the specific conditions of the position being advertised;
f. have not been definitively convicted of committing a crime against humanity, against the state or against authority.

Article 9. According to Law 183/2024 on the Status of CDI personnel (for the professional grades ACS, CS and CSIII) and the Order of the Ministry of National Education and Scientific Research no. 6129/20.12.2016 (for the professional grades CSII and CSI), minimum standards are established the obligations that must be fulfilled by people participating in the competition to obtain a CDI position.

(1) For the ACS professional degree, the minimum mandatory standards are the following:
a. be a graduate with a bachelor's degree or a diploma of long-term university studies, or graduate with a master's degree in the specialty or a related field;
b. at least two letters of recommendation from supervisors and/or course teachers.

(2) For the professional degree CS, the minimum mandatory standards are the following:
a. meet the conditions for obtaining the ACS degree; b. be enrolled in doctoral school or hold a doctorate in the specialty or fields related.

(3) For the professional degree CSIII, the minimum mandatory standards are the following:
a. to hold a doctorate in the specialty or related fields;

b. at least five articles published in journals indexed in international databases (excluding Google Scholar);
c. at least one paper presented at an international conference.

(4) For the professional degrees CSII and CSI, the minimum mandatory standards are the following:
a. to hold a doctorate in the specialty or related fields;
b. the minimum standards approved by order of the Minister of Education and Research;
c. to hold the qualification certificate (to obtain the CSI degree).

Article 10. The criteria based on which the minimum standards for occupying the positions and professional ranks of the CDI staff of IBPC-NS are developed are the following:
a. the results of research and/or innovation activity;
b. the impact of research and/or innovation activity;
c. the ability to attract research funds or to collaborate with public and/or private research organizations;
d. professional prestige;
e. organizational capacity;
f. international cooperation capacity.

Chapter III. General framework for organizing the competition

Article 11.

(1) IBPC-NS organizes a competition to fill one or more CDI positions only if they are vacant and based on a substantiation note proposing to put the position out to competition.

(2) A position is considered vacant if it is so provided in the annual staff list or if it is vacant during the year.

(3) The position is vacant in one of the following ways:
a. termination of the individual employment contract of the person occupying the position, under the law;
b. the transfer of the person occupying the position to another position within the same organization research, as a result of winning a competition;
c. by suspending the individual employment contract of the person occupying the position, in this case, the temporarily vacant position may be filled for a fixed period until the holder returns to the respective position.

Article 12. The competition procedure is initiated by IBPC-NS only after the Scientific Council approves the organization of the competition.

Article 13. Calendar of competitions for filling vacant positions:
a. the substantiation note is drawn up proposing the opening of the position to competition and is submitted for approval to the Scientific Council of IBPC-NS;
b. after receiving approval, the competition is announced publicly, by posting on the IBPC-NS website and by publishing on https://posturi.gov.ro/.ro;

c. the composition of the competition/appeals committee is established within 5 days of the approval of the competition organization and the schedule, and the decisions to appoint members and designate committee chairmen are drawn up;
d. the available period for submitting the competition file is 30 days (for permanent positions) from the date of publication of the announcement;
e. the competition files are sent to the president of the competition committee;
f. Candidates who have obtained at least an average of 8 and no grade are admitted and can be recommended. sub 7;
g. within 1 working day from the date of publication of the competition result, candidates have the right to file an appeal;
h. appeals are resolved within 2 working days of their registration;
i. the final report of the competition, after approval by the Scientific Council, is submitted to Director;
j. within 2 working days from the end of the competition, the final result of the competition is published the competition;
k. The winning competition files are submitted to the Biological Sciences Section within 10 calendar days from the end of the competition;
l. the competition procedure must be completed by the commission within 15 days from the date of registration, and the final report and the complete file must be submitted to the Presidium of the Romanian Academy within 45 days from the same date.

Chapter IV. Publication of the announcement regarding the organization of the competition

Article 14. The competition is publicly announced by posting at the IBPC-NS headquarters, on the IBPC-NS website (www.icbp.ro) and on the website https://posturi.gov.ro/.ro, and can also be distributed on other national and international online platforms, or in printed form in various locations for increased visibility. All announcements contain elements relating to the deadline for submitting applications, the IBPC-NS website and the contact details of the IBPC-NS secretariat, from where any additional information regarding the competition can be obtained.

Article 15. Simultaneously with the publication of the competition announcement, the standard forms (application for registration for the competition, Annex 1A, proposal for scientific career development, Annex 5 and sheets for verifying the fulfillment of the research organization's own standards, are also published on the IBPC-NS website. Annexes 5A, 5A.1-5A.3 and 5Aa) and the following elements: a.
brief description of the position for which the competition is being organized (position, COR code, duration individual employment contract, specific duties);
b. the minimum salary corresponding to the position;
c. the topic and bibliography of the competition tests;
d. complete list of documents that make up the competition file;
e. the address to which the competition file can be sent (in physical or electronic format);

f. the organization of the competition (written and/or oral test);
g. the day, time and place of the competition;
h. the calendar/description of the competition procedure.

Chapter V. Competition registration

Article 16. Registration for the competition is made within 30 calendar days from the date of publication of the announcement, by submitting a file by the candidate both in physical format, at the IBPC-NS headquarters, and in electronic format (on a memory stick at the IBPC-NS headquarters and to the e-mail address indicated in the announcement).

Article 17. The file must contain the following documents also provided in Annex DA (each document in the physical file will be scanned according to an inventory, Annex 6A and saved on a memory stick):

a. the signed application for registration for the competition, to which is attached a declaration on one's own responsibility by which the candidate attests to the veracity of the information presented in the file (Annex 1A and Annex 3A);
b. proposal for the development of the scientific career from the point of view of scientific research activities (Annex 5), of maximum 5 pages, signed (for CSI, CSII, CSIII);
c. curriculum vitae according to the EUROPASS model signed by the candidate (Annex 3), which must contain: i. studies completed and diplomas obtained; ii. professional experience and relevant jobs previously held; iii. research, development and innovation projects led as project director and grants obtained, if applicable, indicating for each funding source, the volume of funding and the main publications or patents resulting; iv. awards or other elements of recognition of scientific contributions; v. narrative description of the 3 most important achievements since the last promotion - maximum 3 pages;
d. list of publications, works, articles/studies, patents selected by the candidate based on their relevance to their own scientific research activities, signed in original by the candidate (Annex 4). The list must necessarily contain: i. list of no more than 10 scientific publications, the most relevant, such as: author's books, articles/studies/ chapters, edited volumes, works; ii. list of patents and other industrial property titles; iii. list of author's books and edited and published volumes; iv. list of articles/studies in extenso, published in journals from the main international scientific flow; v. list of other scientific works and contributions;
e. verification sheet of compliance with the research organization's own standards, completed and signed by the candidate (Annexes 5A), except for the situation regulated in letter f;
f. proof of holding the professional research and development degree corresponding to the position for which they are applying, the verification form of meeting the research organization's own standards, completed and signed by the candidate, only for candidates who hold the professional research and development degree of CS II or CS I corresponding to the position for which they are applying

run for office;

g. copy of the bachelor's degree or equivalent/master's degree/doctorate, as the case may be. In the event that the candidate declared the winner does not hold a diploma issued by a higher education institution in Romania, he/she must submit a copy of the original of the certificate of recognition or equivalence thereof before being hired and signing the individual employment contract, under penalty of not issuing the administrative act of hiring for the position;

h. copy of the identity card or any other document attesting identity, according to the law, as the case may be, certified by the candidate according to the original, the name in clear print and the signature;

i. copy of the marriage certificate or proof of name change, as applicable, certified by the candidate according to the original, the name in print and the signature;

j. medical certificate attesting to the candidate's appropriate health status, issued by the candidate's family doctor or by the authorized health units no later than 3 months prior to the competition;

k. signed declaration of consent for the processing of personal data (Annex 4A);

l. criminal record certificate;

m. birth certificate, certified by the candidate as being in accordance with the original, the name clearly and signature.

The competition file for the position of CSI, CSII consists of 2 parts (the administrative file and the folder with scientific papers), and the documents contained (according to Annex DA) will be assigned a link according to the procedural steps in Annex L.

Article 18. The secretary of the competition committee registers the competition file, communicates the registration number to the candidate and transmits the file to the members of the competition committee, under the conditions established by the competition regulations.

Article 19. The secretary of the competition committee shall verify whether the competition file is complete on the day of its receipt and registration. In the event that the competition file is incomplete, the secretary of the competition committee shall request clarifications from the candidate, and the candidate may complete the competition file until the date on which the period for submitting competition files expires.

Article 20. In exercising the duties provided for in Articles 18 and 19, the secretary of the competition committee collaborates with the human resources manager, under the conditions provided for in the competition committee's own regulations. contest.

Chapter VI. Competition committee and appeals resolution committee

Article 21. Within 5 days of the approval of the organization of the competition and the schedule of its implementation, the nominal composition of the competition commission and the one for resolving complaints shall be established, for each vacant position for which a competition is organized, following the proposals

the scientific director/secretary, approval by the Scientific Council of IBPC-NS and endorsement by the Biological Sciences Section of the Romanian Academy.

Article 22.

(1) The members of the competition committee and those of the appeals resolution committee are scientific researchers or university teachers with a professional degree or university teaching title at least equal to the professional degree for which the competition is organized and are specialists in the field of the vacant position's disciplines or in related fields.

(2) The members of the competition committee cannot be part of the appeals resolution committee.

(3) The persons involved in the competition procedure are: a. participating

in the decision-making process regarding the appointment of the competition committee and the selection committee.

resolution of complaints;

b. participates in the professional or administrative evaluation within the competition.

(4) Persons who are spouses, relatives or in-laws up to the third degree inclusive in relation to the candidate in the competition for a vacant position may not be involved in the competition procedure.
research.

Article 23. The composition of the competition committee is appointed by administrative act of the director of IBPC-NS and is composed of:

a. of 3 members, in the case of the competition for ACS, CS and CSIII;

b. of 5 members, of which at least 3 are from outside IBPC-NS, for CSII and CSI.

Article 24. The composition of the appeals resolution committee is appointed by administrative act of the IBPC-NS director and is composed of 3 members.

Article 25. The work of the competition committee and the appeals resolution committee is led by one of the two members of each committee, affiliated with IBPC-NS, as president, appointed by decision by the Director of IBPC-NS.

Article 26. The competition committee and the appeals settlement committee benefit from administrative support from IBPC-NS, provided by a secretary appointed by administrative act of the Director, who is not a member of the competition committee and does not take part in the committee's decisions.

Article 27. In well-justified situations, illness, internal/external travel (business interests), at most one member of the competition committee may participate in the online videoconference system. The recording of the meeting will be part of the competition file.

Article 28. The decisions of the competition committee and those of the appeals resolution committee are taken by open vote of the members and must meet the favorable vote of at least half plus one of the number of component members.

VII. Competition evaluation

Article 29. The competition consists of evaluating the scientific activity and research skills of the candidates for the vacant positions put up for competition, according to the evaluation criteria and its own grading scales established internally and approved by the Scientific Council of IBPC-NS (Annex SC.C and Annex GN).

Article 30. The competition for filling vacant positions of ACS and CS consists of *written, oral and/ or practical and file tests,* specific to the position and is evaluated as follows:

a. the result of the competition tests is assessed by each member of the competition committee through rating from 1.00 to 10.00;
b. the grade of each competition test represents the arithmetic average of the grades awarded by each member of the competition committee;
c. the final score represents the arithmetic average of the marks of the competition tests;
d. a candidate can only be declared the winner if he/she obtained a final score of at least 8.00 and no score below 7.00 in the competition tests;
e. The Scientific Council analyzes compliance with the procedures established by its own regulations. contest and approves the report on the contest by open roll call vote;
f. the weight of the competition tests in the final result is calculated as follows:
i) for ACS: written test (50%), oral test (50%) ii) for CS: file evaluation (33.3%), written test (33.3%), oral test (33.3%)

Article 31. The competition for filling the vacant positions of CSIII, CSII and CSI consists of *analyzing the application file for the competition* and awarding points, based on a grid adapted to the specifics of the candidate's job activity and his/her performance, and may *also include an interview test.* The evaluation process is carried out as follows:

a. after analyzing the competition file, each member of the competition committee awards a score, based on a grid adapted to the specifics of the candidate's job activity, in accordance with the thresholds established by the minimum standards and by the research organization's own standards, as appropriate;

b. the individual score awarded by a member of the competition committee represents the sum of the scores obtained by the candidate, related to each quantitative threshold in the research organization's own standards.

c. the total score represents the arithmetic average of the individual scores given by the members the commission;
d. if the competition also includes an interview test, a score is awarded that represents the arithmetic average of the scores awarded by the committee members;
e. the maximum score of the interview test cannot exceed 20% of the total calculated score;
f. the final score represents the sum of the scores awarded following the analysis of the file and the interview;
g. The Scientific Council analyzes compliance with the procedures established by its own regulations.

contest and approves the report on the contest, by open roll call vote;

h. the weight of the competition tests in the final result is calculated as follows:

i) for CSIII: file evaluation (80%) and interview test (20%);

ii) for CSI and CSII: file evaluation (100%).

Article 32. The result of the competition is analyzed and approved by the Scientific Council of IBPC-NS, the final score being calculated according to the formulas:

a. for ACS: Pfinal = (Pscris + Poral)/2; b. for CS:

Pfinal = (Pscris + Poral + Pdosar)/3;

c. for CSIII: Pfinal = Pfile × 80% + Pinterview × 20%;

d. for CSII and CSI: Pfinal = Pdosar.

Article 33. If the competition includes written, oral and/or practical tests, respectively an interview, the competition committee evaluates the candidate from the perspective of the following non-cumulative criteria:

a. the relevance of the results of the research and/or innovation activity, in relation to the topic of the position for which they are running;

b. the impact of the candidate's research and/or innovation activity and scientific results, in relation to the topic of the position for which he/she is applying, reflected in scientific publications;

c. the international scope of activities, reflected in scientific publications, patents, participation in scientific conferences, individual and institutional collaborations, projects, prestigious scholarships, the quality of visiting professor/researcher, and membership in the editorial boards of top journals in the field;

d. the ability to attract research funds or to collaborate with public and/or private research organizations and to lead research and development projects;

e. professional prestige;

f. organizational capacity;

g. ability to mentor young researchers or students;

h. the ability to transfer knowledge and results to the economic or social environment or to popularize one's own scientific results;

i. the ability to work in a team and the efficiency of his/her scientific collaborations, depending on the specifics of the candidate's field;

j. professional experience in institutions other than the institution organizing the competition.

Chapter VIII. Competition results

Article 34.

(1) Following the completion of the evaluation process, the competition committee establishes, for each position, the hierarchy of candidates and nominates the candidate who obtained the best results in relation to the final score calculated.

(2) The president of the competition committee draws up a report on the competition (Annex 3C), signed by each member of the committee and based on the evaluation reports (Annex 2C) drawn up by

each member of the competition committee and respecting the hierarchy of candidates decided by the selection committee contest.

(3) The Scientific Council, after analyzing the report and related documentation received from the president of the competition committee, verifies compliance with the procedures established by the competition regulations and approves or not the report on the competition, by open roll call vote. The Scientific Council cannot modify the hierarchy of candidates resulting from the evaluation carried out by the competition committee.
contest.

(4) After the approval of the files and the approval of the competition committee report by the Scientific Council, it is submitted to the Director of IBPC-NS.

Article 35.

(1) The competition files for obtaining the degrees of ACS, CS, CSIII, CSII and CSI are submitted by the IBPC-NS within 10 calendar days from the completion of the competition to the Biological Sciences Section, which within a maximum of 15 calendar days will analyze the file for the award of the professional degree of research and development. In case of favorable approval, it will forward the file to the Legal and Communication Service for verification.

(2) The Legal and Communication Service will approve the file regarding the legality of the competition within a maximum of 15 calendar days from the receipt of the file from the Biological Sciences Section. In case of favorable approval, it will forward the file to the Research and Doctoral Programs Service.
(3) The Research and Doctoral Programs Service will submit for approval to the Presidium of the Romanian Academy, within a maximum of 5 calendar days, the competition files that have obtained the favorable opinion of the Biological Sciences Section and the Legal and Communication Service.
(4) After the approval of the results of the promotion exam by the Presidium of the Romanian Academy, the files are returned to IBPC-NS.

Article 36.

(1) If, following the administrative analysis, it is found that the competition file is incomplete or does not comply with the legal regulations in force, as well as the provisions of the institute's own competition regulations, the competition file is returned to IBPC-NS. **(2)** Within 15 days from the date of return, IBPC-NS is obliged to update it,
so that the legal provisions are respected and to resend it to the Biological Sciences Section/Service that found the non-compliance with the legal regulations in force.

(3) If it is not possible to complete the file of the candidate declared the winner, so as to comply with the legal regulations in force, as well as the provisions of the IBPC-NS regulation, the candidate in the next place is declared the winner, and his file is sent to the Biological Sciences Section/Service that found the non-compliance with the legal regulations in force, for administrative analysis, in compliance with the provisions of paragraph (1). **(4)** If there is no longer any candidate who meets the conditions, the competition is resumed without the need for a new
approval for its organization.

Article 37.

(1) The duration and completion of the competition is 15 calendar days from the date of closing the registration for the competition, at the level of the competition committee, and 45 calendar days until the submission of the report of the competition committee and the file containing the documents related to the competition to the Presidium of the Romanian Academy.

(2) The result of the competition is posted at the IBPC-NS headquarters and on its website, within 2 working days from the end of the competition.

Article 38.

(1) Contest candidates dissatisfied with the decision may file appeals within 1 working day from the date of publication of the contest result, which will be submitted to the same e-mail address in the announcement.
(2) The secretary of the commission shall forward the appeals to the appeals resolution commission, which shall resolve them within 2 working days of their registration.
(3) The chairman of the appeals resolution committee shall draw up a report on the appeals (Annex 3C) submitted, signed by each member of the committee and based on the reports written (Annex 2C) by them.

(4) The Scientific Council, following the analysis of the report and related documentation received from the president of the appeals resolution committee, approves or denies the report on the submitted appeals, which is finally submitted to the Director of IBPC-NS.
(5) The final results of the competition are displayed and within 5 working days of the display, they must be published on the institute's website together with the CV, the verification sheet of the fulfillment of the institute's own standards and the List of scientific publications of the candidate declared admitted. **(6)** If the vacant position for which the competition is organized has not been filled, the competition
can be resumed, in compliance with the legislation in force.

Chapter IX. Recruitment

Article 39. The professional degrees of ACS, CS, CSIII, CSII and CSI of the IBPC-NS are granted by decision of the President of the Romanian Academy, following the approval of the results of the public competition by the Presidium of the Romanian Academy.

Article 40. IBPC-NS prepares a summary report (Annex 7) on the organization and conduct of the competition, which is sent annually, within 15 calendar days from the end of the calendar year for which the report is made, both in physical format with the forwarding address, to the Research and Doctoral Programs Service, and in electronic format to the email address bpg@acad.ro.

Article 41. The recruitment of RDI personnel to positions corresponding to their professional functions and grades is carried out according to the principle of professional merit, based on certain procedures.

transparent and fair procedures that respect the general principles and conditions set out in the European Charter for Researchers.

Article 42. The personal data of the persons involved in the examination process are processed within the IT platform, in compliance with the provisions of Regulation (EU) 2016/679 on the protection of natural persons with regard to the processing of personal data and on the free movement of such data, and repealing Directive 95/46/EC (General Data Protection Regulation).

Article 43. Annexes SC.C, DA, L, 1-5GN, 1A-6A, 1C-4C, 1-9, 1.1C-1.3C, 2.1C and 2.2, are part of this Regulation and together with it, have been established and drawn up by IBPC-NS in accordance with the regulations and models proposed by the Romanian Academy within the Methodological Norms regarding the organization of the competition for filling vacant positions of CDI in the institutes of the Romanian Academy/July 15, 2025. These are the only documents recommended for use in the conduct of the competition, being made available to all personnel involved in the competition procedure, through the official website of IBPC-NS and the common partition on the institution's intranet.

These regulations, in their revised form, approved at the meeting of the Scientific Council of IBPC-NS on 13.01.2026, replace the old Regulation of 6.10.2025. Furthermore, these regulations may be adjusted by the calibration provided by the competitions for each category (scientific degree) that will continue to be held.

Tissue engineering of blood vessels using three-dimensional bioprinting of endothelial and smooth muscle progenitor cells

PN-III P1-1.1-PD-2016-1660

Phase I report – 2018

Abstract

3D Bioprinting uses 3D printing techniques for making tissues and organs that mimic the natural tissue architecture. Cells, growth factors and biomaterials are associated in a "bioink" that can be printed using the 3D bioprinter to create structures in which cells grow and differentiate. Amniotic fluid stem cells are easy to obtain, have a high proliferation rate, a normal karyotype, long telomeres, do not form tumours, have immunomodulatory capacity and are multipotent. Using 3D bioprinting, the proposed model was constructed, having a uniform tubular structure, resistant to subsequent histological processes, suggesting good resistance and elasticity. The optimal parameters for printing were: 1.1 to 1.2 bar pressure, 1 mm / sec print speed using a 0.2 mm internal needle, temperature 18ºC, ultraviolet polymerization 5 seconds / layer, layers number 10, diameter of construct 2.5 mm. Using these parameters were made vascular constructs with a diameter of 2.46 mm, a wall thickness of 1.4 mm and a height of 2.79 mm. In the optical microscopy using histological staining of the vascular construct sections was observed a network formed by the collagen, hyaluronic acid and polyethylene glycol hydrogel that could permit the attachment of cells and nutrients diffusion. Biological fluids up-take and enzymatic degradation tests that vascular constructs are hydrophilic and biodegradable. Cells isolate from amniotic fluid are mesenchymal stem cells with a fibroblast-like phenotype and an increased expression of the pluripotent markers SSEA-1, SSEA-4, TRA1-60, TRA1-81, and mesenchymal markers CD29, CD49e, CD56, CD73, CD90. Endothelial differentiation was performed within 4 weeks; AFSC altering its fibroblast-like phenotype in an endothelial-like phenotype, ultrastructural characterized by the presence of plasmalemmal endocytosis vesicles. Flow cytometry analysis showed the presence of endothelial cell-specific surface markers, such as CD29, CD31, CD44, CD54, and CD105. In conclusion, collagen and hyaluronic acid hydrogel allow the manufacture of vascular constructs, the parameters of the 3D bioprinter have been optimized so that the vascular model to be similar to the model designed in the BIOCAD software.

Introduction

3D Bioprinting uses 3D printing techniques for manufacture tissues, and organs that mimic the architecture of natural tissues. This technique combines cells, growth factors and biomaterials to create an environment in which cells grow and differentiate into native tissue-like structures. In 3D bioprinting, biomaterials are printed layer by layer to produce structures similar to a desired organ or tissue. The first patent for this technology was proposed in the United States in 2003 and granted in 2006 [1]. Bioprinting involves several steps including: (i) biomaterial selection, (ii) creating a bioprinting pattern using CAM software, (iii) bioprinting using dedicated bioprinters, and (iv) analysing bioprinting constructions. In 3D bioprinting an exhaustive, knowledge and methodology approach is needed using knowledge from various fields such as engineering, tissue engineering, stem cell biology and the science of biomaterials to create an ideal model. An ideal scaffold should be biocompatible, non-immunogenic, non-toxic, anti-thrombotic, with vasoactive properties, and should allow remodelling of the post-implant host tissue. To create such a scaffold, physicochemical parameters such as geometry, surface properties, pore size, adhesion, degradation and biocompatibility should be analysed [2, 3]. Although there is a wide variety of biological materials, including hydrogels, extracellular matrix, fibrillated polymers, microcarrier structures, and cell aggregates, several aspects have to be considered for obtaining structures similar to the target tissue. First of all, an important aspect is *compatibility* with the different types of printing. Extrusion printing is the most flexible method due to the mechanism and larger diameters of printheads. Drop or laser printing is only used for hydrogels. The second aspect is the *bioprintability* of scaffolds. In this case, the bioprinting of hydrogels is superior to other bioinks. The third aspect is *replicability,* the constructs should be as close as possible to the desired tissue. Scaffold degradation, cell interactions and proliferation are important for tissue formation. The fourth aspect is related to the *bioprinting resolution*, which depends on bioprinting type as well as on bioink. Laser bioprinting of hydrogels has a resolution of 5.6 ± 2.5 μm, while the drop or extrusion bioprinting between 50-100 μm. The fifth aspect is *accessibility*. Matrigel ™, fibrin and collagen hydrogels are expensive compared to synthetic polymers. In a scaffold, hundreds of millions of cells are needed so that obtaining them could be intensive, costly and time-consuming.

Other aspects involve: scalability, practicality, mechanical and structural integrity, degradability, commercial availability, immunogenicity and applicability. Despite the multitude of biomaterials that appear daily, relatively little research has been devoted to the development of biomaterials for the bioprinting process. Although a large number of hydrogels have great potential for tissue engineering, only a limited number can be used in bioprinting due to the lack of bioprintability and toxicity of degradation products and to the bioprinter parameters that should be optimized for each specific tissue. There are essential improvements in bioinks technology for bioprinting. In the near future there will be a new field such as developing and designing new materials for bioprinting. The main objectives for improving bioprinting are to minimize cell loss, promote cell-cell interactions, increase mechanical properties, and biocompatibility of 3D bioprinting scaffolds. In the future, new biological materials compatible with 3D bioprinting processes will advance research in the field of tissue engineering and regenerative medicine. Amniotic fluid cells are a heterogeneous population of mesenchymal cells of fetal origin of great importance in regenerative medicine. This population is known to have low immunogenicity, so it is less likely to generate an immune response thus having a high therapeutic potential [4, 5]. Phenotypes found in cell culture in amniotic fluid include epithelial-like and fibroblast-like cells [6]. There are also approximately 0.1-0.5% stem cells defined by c-kit expression (CD117 +) on the cell surface. The regenerative potential of amniotic fluid-derived mesenchymal stem cells (AFSC) derives from their ability to differentiate and reduce immunogenicity [7]. AFSC can differentiate into different cell lines, such as endothelial [8], cardiac [9], neural, bone [10]. AFSC can also be reprogrammed without the use of gene transfer technology for induction of pluripotent stem cells [11]. The literature suggests a strong correlation between AFSC and the cardiovascular system. AFSC have demonstrated the ability to form capillary-like networks when grown in hydrogels and there is also evidence of paracrine signalling when AFSC are indirectly co-cultivated with human cardiac cells thereby modulating cardiac regeneration [13].

The project aims is to develop vascular structures using polymeric hydrogels and endothelial and muscle progenitor cells derived from AFSC using 3D bioprinting. Thus, the goal for 2018 was "Obtaining and characterizing endothelial and muscle progenitor cells and vascular model" with the following activities:

1. Determining optimal 3D printing parameters and creating vascular structure

2. Testing resorption rate of vascular structures under conditions that mimic biological fluids

3. Morphological and phenotypic characterization of differentiated muscle and endothelial progenitor cells from AFSC

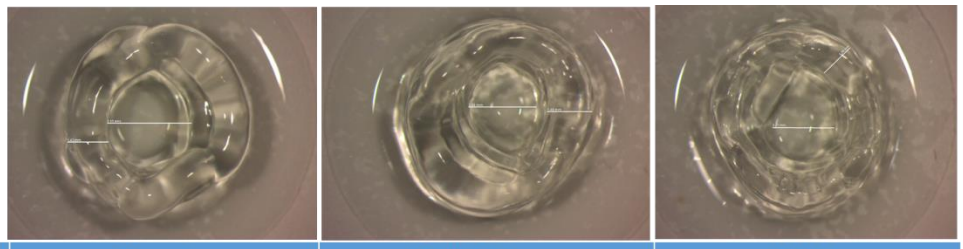
1. Determining optimal 3D printing parameters and creating vascular structure

Establishment of the vascular model was performed using the BIOCAD software. A 10-layer vascular construct having a diameter of 3 mm and a height of 2.5 mm was bioprinted. After each layer, the polymerization module was inserted. A collagen/hyaluronic acid/polyethylene glycol gel was used for printing. The hydrogel polymerization was performed by exposure to UV for 5 seconds / layer. Working pressure has been established according to the physicochemical properties of the printed hydrogel. The optimal pressure is 1.1 - 1.2 bar. Printhead speed is a very important parameter for printing, and is dependent on the physicochemical properties of the hydrogel. At a too high speed it does not close the vascular structure, and at a low speed it creates a thick layer that leads to the formation of a vascular construct over the desired size. The printing speed was set at 1 mm / sec using a needle with 0.2 mm internal diameter. For optimum printing, the hydrogel was printed at 18ºC, with the 3D Discovery bioprinter which have the possibility to adjust the printhead temperature (Figure 1).

Diameter of construct	Number of layers	Pressure	UV	Speed rate	Temperature	Needle diameter
2.5 mm	**10**	**1.1 bar**	**5 seconds**	**1mm/sec**	**18ºC**	**0.2 mm**

Figure 1. Optimal printing parameters of vascular constructs using collagen / hyaluronic acid / polyethylene glycol hydrogel

Using these parameters, vascular constructs with a diameter of 2.46 mm (± 0.41), wall thickness of 1.4 mm (± 0.10) and a height of 2.79 mm (± 0.05) (Figure 2) were bioprinted. These results show that the hydrogel can be used for vascular constructs and meet the desired requirements for reproduce with accuracy the model created in the BIOCAD.



CONSTRUCT	Diameter	Wall thickness	Height
Construct 1	2,95 mm	1,43 mm	2,73 mm
Construct 2	2,24 mm	1,49 mm	2,82 mm
Construct 3	2,21 mm	1,28 mm	2,84 mm

Figure 2. Measurements of bioprinting vascular constructs after optimization of 3D Discovery bioprinter parameters.

The morphological characterization of vascular constructs was performed by optical microscopy after histological preparation and microtome frozen sections of vascular constructs. The sections were stained by Haematoxylin & Eosin and Trichromic Masson techniques. For the microtome sections, constructs were fixed with PFA 4%, 30 minutes at room temperature, then washed with phosphate buffer and passed through 4%, 5%, 10%, 20% and 50% glycerol baths for cryoprotection. The constructs were covered with OCT and cut to the microtome at a thickness of 5µm. The sections were then stained using the classic histological staining techniques.

The results showed that the structures exhibit a tubular, uniform structure, resistant to subsequent histological procedures, which suggests good resistance and elasticity. These latter two aspects will be deepened in stage 2 of the project using rheology and elasticity techniques. Optical microscope imaging of the sections shows a relatively uniform network structure, which would allow the attachment of cells and the exchange of nutrients and gases. By histological staining of the sections, was revealed the network structure of collagen and hyaluronic acid hydrogel (Figure 3).

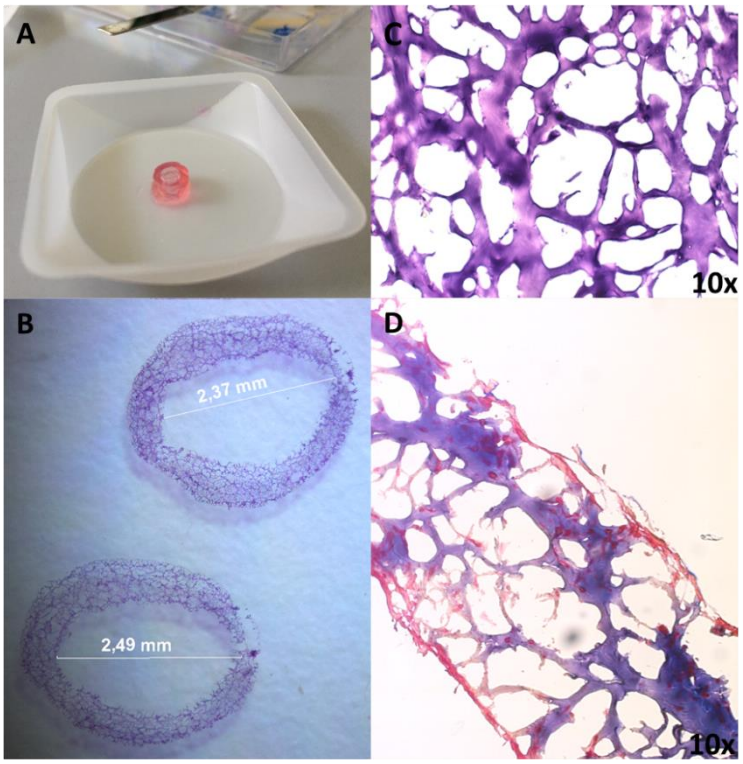


Figure 3. Macroscopic and microscopic morphology of bioprinting vascular constructs. (A) Macroscopic structure of bioprinted vascular construct; (B) Histology sections of vascular constructs; (C) H&E staining and (D) Trichromic Masson of bioprinted of vascular construct sections

2.Resorption rate test of vascular constructs under conditions that mimic biological fluids

Reabsorption experiments were performed to demonstrate the hydrogel behaviour in the presence of water and other fluids. Bioprinting constructs were weighted after printing, then immersed into PBS and weighed at 1, 2, 4, and 24 hours. The resorption rate was calculated according to the formula:

$$\text{Wateruptake} = \frac{Ww - Wd}{Wd(g/g)} \text{ x 100}$$

where: Ww = construct weight after immersion in the fluid at time t; Wd = construct weight before immersion

The results showed that the hydrogel absorbs maximum of PBS at 2 hours after immersion, having a weight gain of 22.32% against the control construct. At 4 and 24 hours the values are similar to those of 1 hour (18%), suggesting that the hydrogel is balanced with the medium within 4 hours (Figure 4).

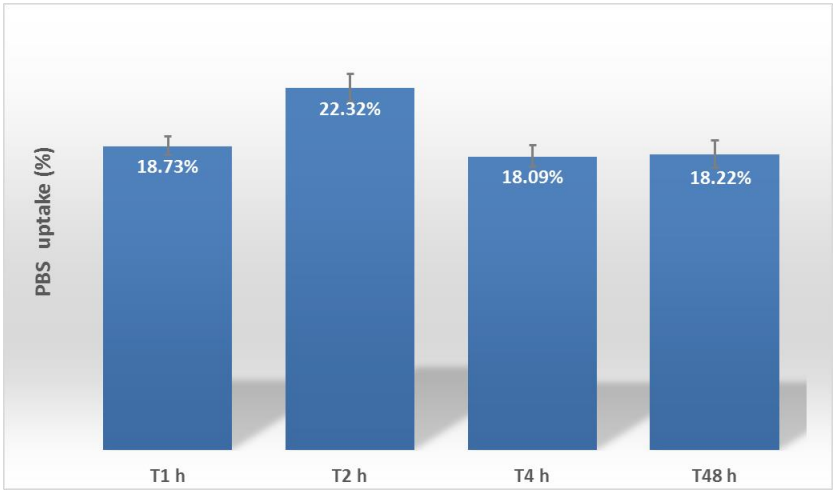

Figure 4. Hydration of bioprinted vascular constructs in saline phosphate buffer

Enzymatic degradation of the constructs was revealed using type I collagenase. Bioprinted vascular constructs were introduced into culture medium (control constructs) and in collagenase type I medium (10 μg / ml and 50 μg / ml) and then weighed at different intervals time (30, 60, and 90 minutes). Weight loss was calculated using formula:

$$\%\text{weight loss} = \frac{Wi - Wt}{Wi \times 100}$$

where: Wi = construct weight in collagenase free medium; Wt = construct weight in collagenase type I medium

The results showed a 36.4% and 47% weight loss respectively at 90 minutes after exposure to 10 μg / ml and 50 μg / ml, collagenase respectively suggesting that the hydrogel is biodegradable (Figure 5).

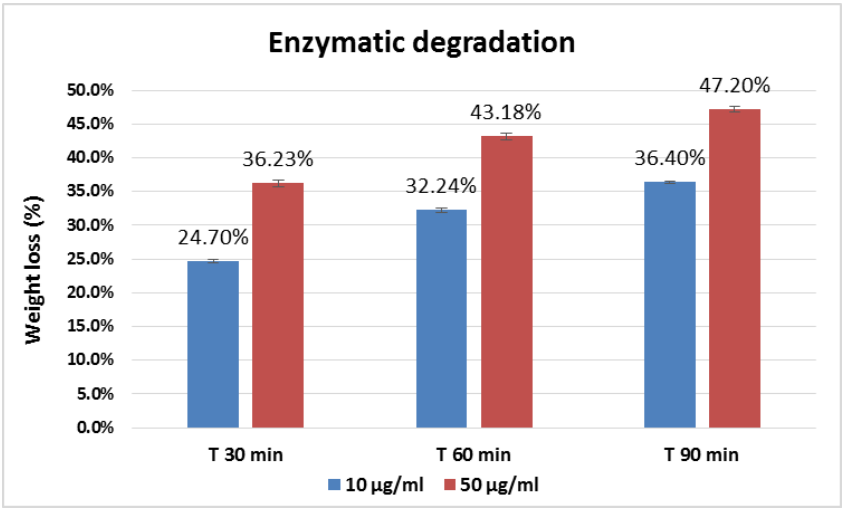

Figure 5. Weight loss of bioprinted vascular constructs as a result of enzymatic degradation using type I collagenase

3. Morphological and phenotypic characterization of differentiated muscle and endothelial progenitor cells from AFSC

Amniotic fluid contains several cell types that result from fetal and embryonic tissues, including a population of mesenchymal stem cells. The advantages of these cells are: easy to obtain (used for prenatal diagnosis, and the rest can be used for research or different clinical applications) have a high proliferation rate (population doubling time is ~ 36 hours), can differentiate into adipose, muscle, cardiac, epithelial, neurons, hepatic cells. They have long telomeres, they do not form tumours, they have immunomodulatory capacity and are multipotent. Cells were harvested by centrifugation of the amniotic fluid for 10 minutes at 400g and cultivation of the sediment in BIOAMF-2 culture medium. After 5 days, the medium was changed to remove non-adherent cells, and then the medium changed twice a week. For cell differentiation, they were grown in EGM-2 medium (Endothelial Growth Medium) supplemented with growth factors: VEGF 40 ng / ml; IGF-1 20 ng / ml; EGF 10 ng / ml; βFGF 10 ng / ml; ECGF 10 μl / ml medium. Cytokines were added every medium changes.

After 4 weeks of growing in endothelial differentiation medium, AFSC changes its morphology from a fibroblast-like phenotype to an endothelial-like phenotype. By electron microscopy, the presence of plasmalemmal vesicles was observed suggesting that they had endocytosis capacity like endothelial cells (Figure 6).

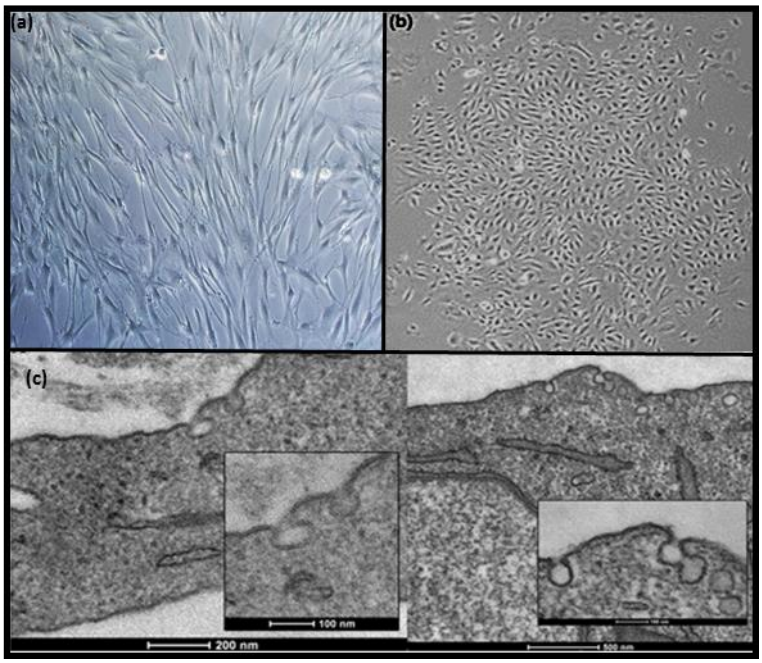

Figure 6. AFSC morphology cultured in BIOAMF medium and in EGM-2 endothelial differentiation medium supplemented with 40 ng / ml VEGF growth factors; IGF-1 20 ng / ml; EGF 10 ng / ml; βFGF 10 ng / ml, ECGF 10 µl / ml. (a) AFSC cultured in BIOAMF medium presents a fibroblast-like phenotype. (b) AFSC cultivated for 4 weeks in the EGM-2 medium shows an epithelial-like phenotype. (c) The AFSC ultrastructure cultivated in EGM-2 differentiation medium revealed the presence of plasmalemmal vesicles.

AFSC immunophenotype before and after differentiation was assessed by flow cytometry technique. Pluripotent markers (SSEA-1 SSEA-4, TRA1-60, TRA1-81) and markers specific for mesenchymal and endothelial stem cells: CD29, CD31, CD44, CD49e, CD54, CD56, CD73, CD90, CD133 was used for characterisation. AFSC were trypsinized and labelled with PE or FITC-antibodies (100,000 cells / 10 µl antibody). The cells were incubated 1 hour at room temperature in the dark, then washed with PBS and centrifuged for 10 minutes at 300g to remove unbound antibodies. The cell pellet was mixed in 300 µl of PBS and analysed on the Gallios flow cytometer (Beckman Coulter).

The results showed that cells isolated from amniotic fluid are stem cells with increased expression of SSEA-1 (72.8%), SSEA-4 (85.3%), TRA1-60 (94.5%) and TRA1-81 (89.2) %) (Figure 7).

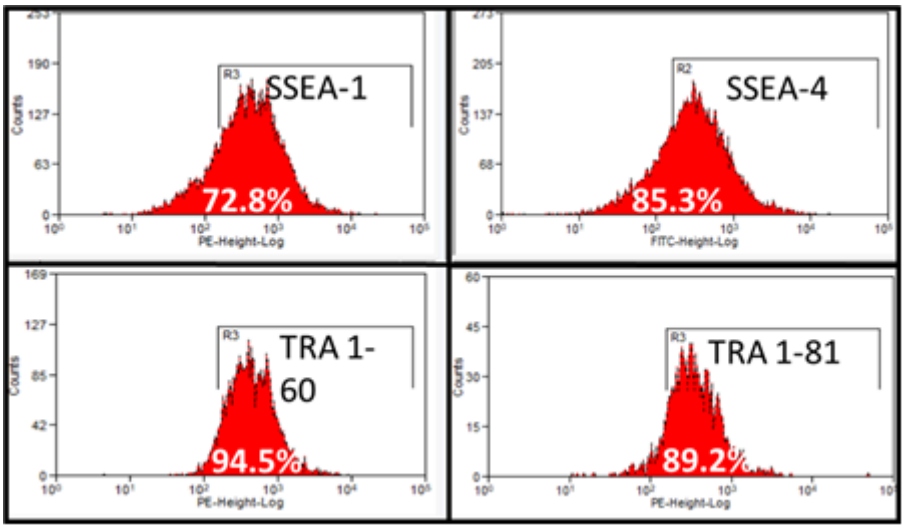

Figure 7. Stem cell-specific pluripotent markers present on the undifferentiated AFSC surface

AFSC cultured in BIOAMF medium exhibits a mesenchymal phenotype characterized by surface markers CD29 (54.8%), CD44 (22.8%), CD49e (99.8%), CD56 (75.2%), CD73 (97.5%), CD90 (98.4% (Figure 8). CD29 is β1 integrin, associates with integrin α1 and α2 forming collagen receptors. It is expressed on the surface of mesenchymal cells and generally on the surface of the adherent cells where it binds the actin cytoskeleton with the extracellular matrix and transmits two-way signals between the extracellular matrix and the cytoplasm. Homing cellular adhesion molecule (HCAM) is a surface glycoprotein involved in cell-cell interactions in cell adhesion and migration. CD44 may also function as a receptor for hyaluronic acid and may interact with other ligands such as osteopontin, collagen and matrix metalloproteinases. CD49e is α5 integrin which in combination with β1 integrin forms the fibronectin receptor. CD56 (NCAM) is part of the adhesion molecule family being neuronal cells. Data from the literature and previous results have shown that AFSC have an increased potential for differentiation in neural cells, so the medium in which they are cultivated and the duration of cell cultures is very important [13]. CD73 and CD90 are markers specific to mesenchymal adherent cells.

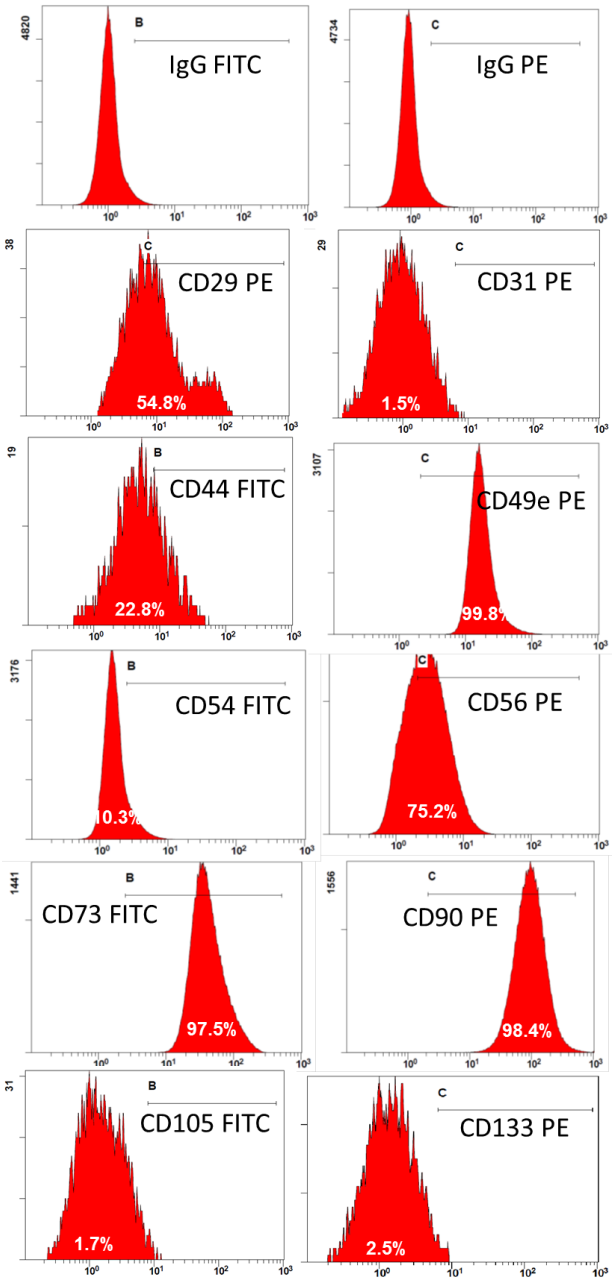

Figure 8. Immunophenotype profile of AFSC cultivated in BIOAMF medium

After growing AFSC in EGM-2 medium supplemented with 40 ng / ml VEGF growth factors, 20 ng / ml IGF-1, 10 ng / ml EGF, 10 ng / ml βFGF and 10 µl / ml ECGF for 4 weeks flow cytometry assay showed the presence of endothelial cell-specific surface markers. Expression of CD29 (98.4%) increased in EGM-2, and CD56 (12%) decreased, suggesting that cells switched neuronal differentiation to an endothelial phenotype. Endothelial cell markers present on the surface of cells were: CD31 (50.7%), CD54 (58.3%), CD105 (67.2%) (Figure 9). CD31 (platelet endothelial cell adhesion molecule) is a platelet and endothelial cell specific adhesion molecule

involved in angiogenesis, vasculogenesis, integrin activation and leukocyte migration. Intercellular adhesion molecule 1 (ICAM-1) is an immunoglobulin family glycoprotein mediated on the surface of immune and endothelial cells, facilitating transmigration of leukocytes through vascular endothelium. CD105 (endoglin) is a protein involved in angiogenesis being found on the surface of vascular and endothelial progenitor cells.

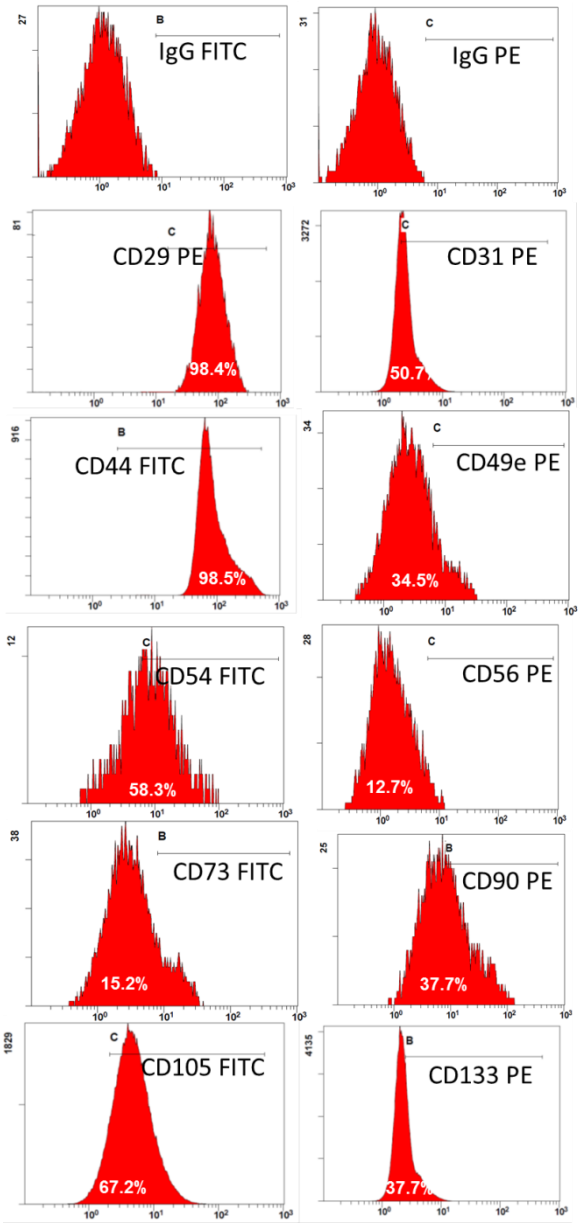

Figure 9. Immunophenotype profile of AFSC cultivated in the endothelial differentiation medium EGM-2

In conclusion, the collagen/hyaluronic acid hydrogel allows the creation of the vascular constructs; the parameters of the 3D bioprinter have been optimized so that a vascular structure similar to the model developed in the BIOCAD program can be created. Amniotic fluid isolated cells are mesenchymal stem cells with potential for differentiation to other cell lines. Following the project, the cells will be differentiated into endothelial and muscle cells and then incorporated into the hydrogel and bioprinting of the vascular structure. Furthermore the bioprinted constructs will be characterized regarding biocompatibility and interactions between cells.

Thesis abstract

Importance of the study

Understanding the mechanisms which lead to differentiation of stem cells is the primary focus of numerous studies. Accessibility of DNA to transcription factors depends on chromatin structure and its degree of compaction. Recent analysis of epigenetic changes in human and murine stem cells have provided new data on the properties of pluripotency of stem cells and their differentiation capacity. These mechanisms lead to a hierarchy of transcription, are mediated by transcription factors and are designed to control gene expression without altering the DNA. Multipotent stem cell capacity decreases with time due to repression of certain genes that presents an epigenetic "signature". Active genes in the stem cells are silent gradually with the passing of their progenitors, and another subset of tissue - specific genes are activated. This progression is achieved by selective expression of transcription factors that recognize and interact with various epigenetic changes in the chromatin. As a result of these events, chromatin becomes accessible for transcription in certain regions, allowing the necessary spatial and temporal control for stem cell differentiation. For example, protein HP1 (heterochromatin protein 1) distribution changes from a dispersed localization in embryonic stem cells to build more concentrated in distinct loci during cell differentiation. Histone acetylation was seen as a phenomenon correlated with an open chromatin conformation that allowed the expression of different genes involved in differentiation. Currently it has been observed that in acetylated state, many genes are repressed and thus differentiation to a specific cell line is blocked, maintaining the pluripotent state. Handling histone deacetylase activity could be a useful tool to generate specific cell populations in order to use them in transplantation. Discovering patterns of acetylation ("acetylation signature") involved in the differentiation of stem cells to different cell types, opening new opportunities at the interface between chemistry and stem cell biology, and can provide valuable information to improve applications of stem cells in tissue engineering and regenerative medicine.

In this context, **the aim of the thesis** is to investigate the role of histone acetylation in the differentiation of endothelial progenitor cells by analyzing the expression of different genetic markers and transcription factors that regulate the activity of these genes. Also, these studies investigate the effect of endothelial progenitor cells acetylation on the process of *„in vitro”* neovascularization.

The thesis is divided into two main parts: Part I - Current state of knowledge and Part II - Original contributions.

The first part presents the current state of knowledge and is organized into three sections.

Subchapter I present notions about the characteristics and properties of stem cells. In this chapter is presented the cell model used in the thesis, represented by endothelial progenitor cells and their potential clinical applications.

Subchapter II makes an overview of the main epigenetic modifications. It describes the mechanisms of action of these modifications and the enzymes involved in their implementation. Also in this section describes the role of epigenetic changes in stem cell differentiation to various cell lines.

Subchapter III describes the mechanisms of histone acetylation and their role in stem cell differentiation. This chapter presents the main classes of histone acetyltransferase and histone deacetylases, histone acetylation mechanisms of action and influenceof acetylation in endothelial progenitor cell differentiation.

In Part II - "Original Contributions" are presented the results of experiments aimed to investigating the role of histone acetylation in the differentiation of endothelial progenitor cells and in neovascularization *in vitro*.

Chapter II.2 - " Materials and Methods " describes the main materials and techniques used in the experiments, including many molecular and cell biology techniques: Real -Time PCR, Western blot, flow cytometry, transmission electron microscopy and scanning electron microscopy, immunocytochemistry and immunohistochemistry, colorimetric and fluorimetric methods.

Chapter II.3 - " Results and discussion " presents the main original results obtained in the studies.

Results and discussion

Understanding the mechanisms which lead to the differentiation of stem cells is the primary focus of numerous studies. Recent analysis of epigenetic changes in human and murine stem cells have provided new data on the properties of pluripotecy of stem cells and their differentiation capacity. These mechanisms lead to a hierarchy of transcription, are mediated by transcription factors and are designed to control gene expression without altering the DNA. Histone acetylation was seen as a phenomenon correlated with an open chromatin conformation, allowing the expression of various genes involved in differentiation.

Currently it has been observed that in acetylated state, many genes are repressed and thus differentiation to a specific cell line is blocked, maintaining the pluripotent state.

In this thesis we have shown that umbilical cord blood contains a rich population of endothelial progenitor cells with an characteristic immunophenotype profile: CD31, CD34, CD133, CD144, CD146, VEGFR2. Molecular analysis of cells obtained from umbilical cord blood showed the presence of genes that are involved in cardiovascular morphogenesis, such as genes for transcription factors GATA2, GATA3, GATA4, and genes that are characteristic of endothelial cells: CD31, VE- cadherin, VEGFR1, VEGFR2, vWF, CXCR4, Tie -2. We have also shown that endothelial progenitor cells have a high capacity of proliferation and migration in comparison with other fetal stem cells types. These cells can uptake acetylated LDL, and *Ulex europaeus* lectin, can form vascular network, suggesting their potential in angiogenesis and vascular repair. This was confirmed using murine embryonic ventricular sections viable or subjected to ischemia, in which we showed that endothelial progenitor cells have the ability to integrate and form vascular networks. Our results indicated that endothelial progenitor cells forming the vascular structures only on viable murine embryonic ventricular sections, while in the ischemic sections only integrate, which demonstrates a direct cell-to cell communication.

The results showed that histone acetylation inhibit the differentiation of endothelial progenitor cells. Inhibitors of deacetylation (VPA, TSA, BuA) mentain chromatin in an acetylated state corresponding to a decondensate conformation. Histone deacetylases level was significantly decreased in the presence of these inhibitors and histone H3 acetylated level was increased and these changes are correlated with the expression of differentiation markers involved in endothelial progenitor cells commitment. The molecular biology and immunophenotyping data showes that HDAC inhibitors have inhibited the expression of vWF, VEGFR2 , eNOS , CD117 , CD133 , CD144 , CXCR4 and Tie- 2, while the expression of CD34 and CD45 remains unchanged showing that the histone deacetylases are involved in the differentiation of endothelial progenitor cells. VE-cadherin expression was significantly inhibited both at the mRNA and protein level. The mechanism underlying the expression of VE-cadherin may be explained by inability of HoxC6 transcription factor to interact with acetylated histones in order to activate the VE-cadherin promoter. Gene expression of CXCR4, Tie-2 and VEGFR2 significantly decreased after treatment with TSA, the mechanism involved is controlled by Hox transcription factors whose expression is modulated in the presence of these inhibitors. Our results have shown that in the acetylated state HoxD9 expression in endothelial progenitor cells is increased in both gene and protein level.

The process of neovascularization is a complex process involving a series of interconnected steps leading to the formation of new blood vessels when vascular lesions occur in adult bodies. In contrast to angiogenesis, which is the formation of new blood vessels from some pre-existing one, neovascularization takes place via endothelial progenitor cells. These cells are mobilized to migrate, proliferate and differentiate at the target site, under the action of cytokines and the microenvironment. Our results have shown that histone acetylation inhibits neovascularization *in vitro*, acting in the processes of proliferation, adherence, migration and differentiation of endothelial progenitor cells. Endothelial progenitor cells showed a significantly decreased level of telomerase activity in comparison with the control, suggesting a decrease in cell proliferation.

Cell motility assessed using the "*wound-healing assay*" and cell impedance measurement, showed that HDAC inhibitors decrease cell motility at 24 hours after stimulation. In contrast, chemotaxis of endothelial progenitor cells was increased after treatment with HDAC inhibitors, which can be explained by the maintenance of a circulating progenitor phenotype. In the presence of 3 mM VPA our data showed a significant stimulation of chemotaxis of endothelial progenitor cells to angiopoietin, VEGF and SDF. After proliferation, mobilization, migration and adherence of endothelial progenitor cells to the target situs, the last step consists in organizing their vascular network. We analysed also this step in terms of acetylation. Growing on Matrigel in the presence of HDAC inhibitors endothelial progenitor cells can not form vascular networks. To confirm these results we used other collagen-based matrix. The results indicated that endothelial progenitor cells isolated from umbilical cord blood were able to survive and adhere to the collagen matrix. Moreover, these cells emit extensions, interact with each other and with the matrix, forming in the network structure. In acetylated state, endothelial progenitor cells lose this ability, which demonstrates that acetylation inhibits neovascularization potential of endothelial cells *in vitro*.

Handling histone deacetylase activity could be a useful tool to generate specific cell populations for transplantation . Discovering patterns of acetylation ("acetylation signature") involved in the differentiation of stem cells to different cell types, opening new opportunities at the interface between chemistry and stem cell biology, and can provide valuable information to improve applications of stem cells in tissue engineering and regenerative medicine.

SUMMARY

Introduction

Ischaemic and non ischaemic myopathies have as a primary consequence the dysfunction of the left ventricle, which finally leads to heart failure. This impairment of heart function decreases the quality of life, life expectancy and increases medical costs. Thus, it represents one of the major health issues all over the world (McMurray and Pfeffer, 2005). Current therapies improve in some extent the survival of the patients and relieve the symptoms, but until now, an efficient method of reversing the damaged condition of the myocardium to a normal state has not been found (Kuraitis *et al.*, 2011). The recent development of stem cell research could provide an efficient treatment of heart failure, by replacing damaged tissue with healthy and functional myocardium, which would increase the quality of life and survival of patients with various cardiomyopathies.

Mesenchymal stem cells (MSC) isolated from adult bone marrow have been intensively investigated due to their regenerative and immunomodulatory properties. Various studies on animal models showed that the transplantation of MSC in an infracted aria of the myocardium improves the cardiac function by decreasing the apoptotic process and by releasing angiogenic factors (Tang *et al.*, 2005). Nevertheless, the efficiency of differentiation into cardiomyocytes (CMC) is extremely low and it cannot explain the transitory beneficial effect observed in preclinical and clinical studies of MSC transplantation in an infracted myocardium (Rose *et al.*, 2008). Therefore, this effect was attributed to the paracrine action of MSC (Gnecchi *et al.*, 2008). These cells are able to release into the extracellular environment soluble factors (citokines, chemokines and growth factors) which have a protective effect on the injured cells of the ischemic myocardium. Moreover, recently it has been shown that MSC are able to communicate with neighbouring cells through circular membrane fragments called microvezicles. In this way, MSC can secrete various soluble components such as receptors, growth factors, biologically active lipids and nucleic acids (mRNA and microRNA) which are protected against aggressive extracellular environment (Morel *et al.*, 2004; Gatti *et al.*, 2011).

MSC are considered to be used in regenerative medicine because they have several advantages, such as:

(i) these cells can be easily isolated and propagated in culture in order to obtain a high amount of cells, needed in cellular therapy;

(ii) they have low immunogenicicy, which makes them suitable for allogeneic transplant (Dai *et al.*, 2005);

(iii) ethical issues adjacent to other types of stem cells such as embryonic stem cells are avoided.

In this general context, the aim of this thesis was to study the differentiation of progenitor cells, such as MSC isolated from adult bone marrow, into cardiac muscle cells, in order to improve the efficiency of cellular therapy of myocardial infarction. Thus, over the entire period of the doctoral stage, the studies have been focused on understanding the mechanisms by which the heart muscle is damaged during and after myocardial infarction and finding an efficient method of tissue repair. This thesis is composed of two main sections. The first part, structured in four chapters, describes the current status of scientific knowledge on the subject of this thesis, while the second part contains the original contributions of the PhD student.

I. Molecular alterations leading to cardiomyocytes apoptosis in ischaemia-reperfusion

In the first chapter of the original contributions section, the focus of the study was on answering the question whether the ischemia or reperfusion is responsible for inducing the apoptotic process in CMC. Knowing the main stimulus responsible for inducing apoptosis in ischemic myocardium is necessary in order to achieve a therapy able to slow down the progression of heart failure due to loss of contractile tissue. Thus, this study aimed to determine the individual contribution of ischemia, reperfusion and exogenous oxidants to the induction of CMC apoptosis.

The results showed that, reperfusion, rather than ischemia *per se*, was the main inductor of apoptosis in CMC. Exogenous oxidants, brought by reperfusion from the surrounding medium, are responsible for triggering the cell death process. 25-hydroxicholesterol, a component of oxidized LDL, promoted CMC apoptosis by a caspase-3 dependent mechanism. This implied the increased expression of the pro-apoptotic protein Bax, which was regulated at transcriptional level and the post-translational degradation of the anti-apoptotic protein Bcl-2 (Figure 2). The impairment of the pro-and anti-apoptotic protein ratio created favourable conditions for the initiation of the apoptotic process, which could only occur during reperfusion, when the ATP and glucose reserves were restored. The data obtained by performing this study indicated that an antioxidant therapy could play an important role in preventing the loss of viable myocardium through programmed cell death of CMC.

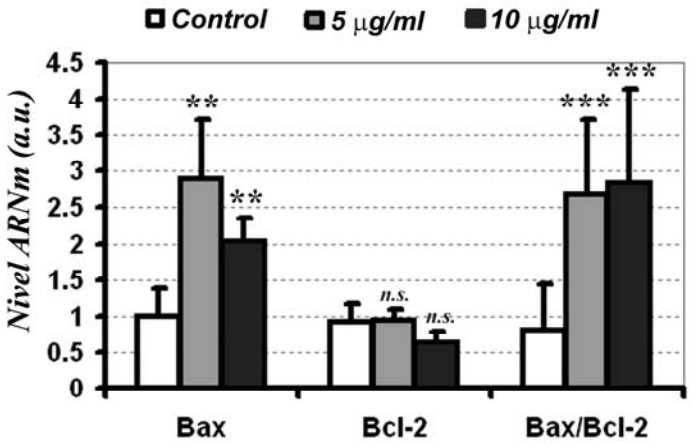

Figure 1: Quantitative RT-PCR illustrating the modification of bax and bcl-2 gene expressions and bax/bcl-2 ratio in CMC after 72 hours of treatment with 25-hydroxicholesterol.

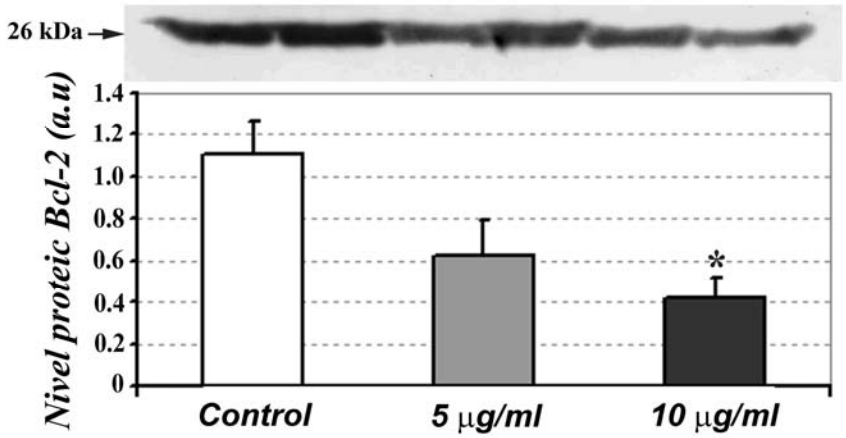

Figure 2: Quantification of the Bcl-2 protein level assessed by Western Blot after 72 hours of treatment with 25-hydroxicholesterol.

II. Isolation of mesenchymal stem cells

An important step of the doctoral stage was the development of a reliable method of isolation mesenchymal stem cells (MSC) for further use in *in vitro* differentiation studies. This presented a special interest because mouse MSC are more difficult to isolate and propagate *in vitro* than human or rat cells, because of the extensive contamination of the adherent culture with cells of haematopoietic origin. For this reason, obtaining a pure mouse MSC culture represented a challenge which resulted in the simultaneously isolation of such cells by two methods. The

homogenous MSC culture was consequently characterized as suggested by the International Society for Cellular Transplant.

II.1. Isolation of stem cells by centrifugation on a discontinuous Percoll gradient

Centrifugation of cells on a discontinuous Percoll gradient (ranging from 1.050 to 1.083 g/cm3) resulted in the recovery of six cell fractions (I–VI), corresponding to the six densities of the gradient: 1.050, 1.057, 1.067, 1.070, 1.076 and 1.083 g/ml (figure 3). Progenitor cells, characterized by the expression of Sca-1 and c-kit markers were found in fractions III-V.

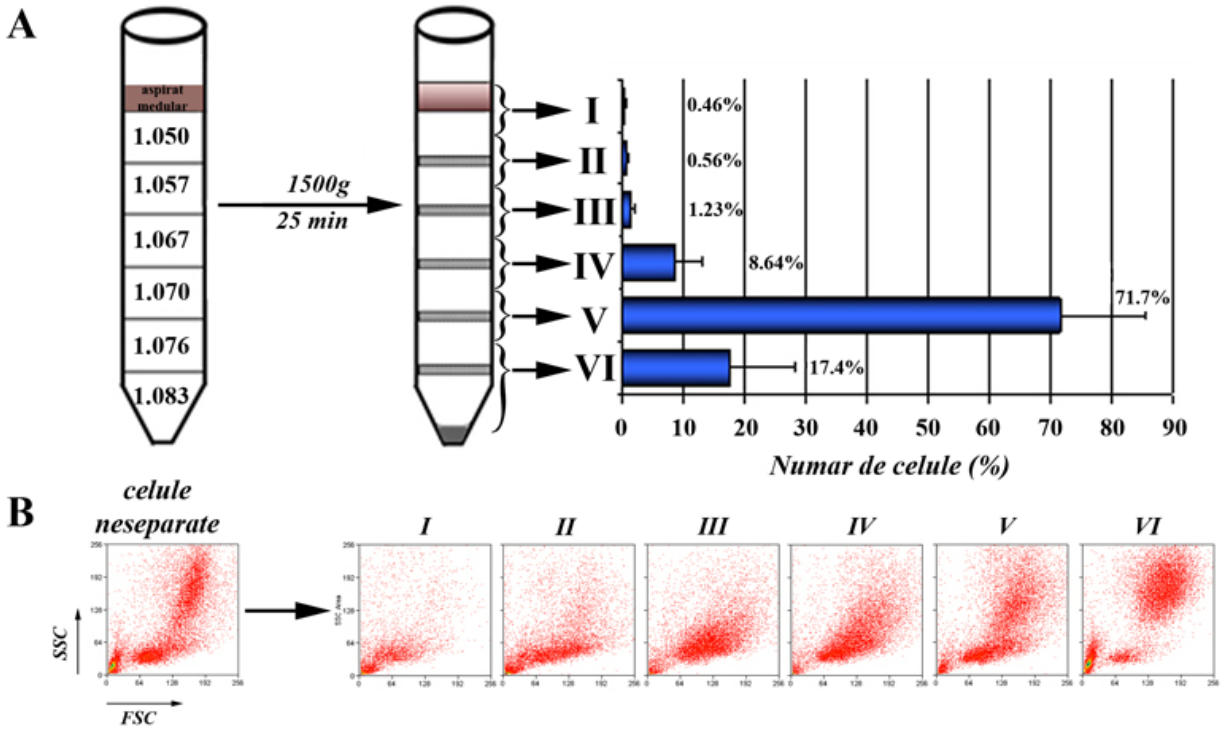

Figure 3: Bone marrow cells separation by centrifugation of Percoll discontinuous gradient. (A) Schematic illustration of the discontinuous Percoll gradient used for fractionation and the percentage of cells segregated in each fraction after centrifugation. (B) Dot-plot histograms resulting from FACS analysis illustrating the heterogeneity of cells before separation and the morphology of cells in each fraction.

The cells in fraction IV, even though they were still heterogeneous, contained a superior amount of haematopoietic progenitors, namely 45% of the population ($2x10^6$ progenitor cells from a total of $4.3x10^6$ cells, figure 4). In addition to c-kit and Sca-1 positive cells, this fraction included endothelial cells, which could play an important role in restoring function of the injured myocardium, by contributing to tissue revascularization by angiogenesis. In culture, this fraction

generated CD45^{-}/c-kit^{-}/Sca-1^{+}/PECAM^{-}/VEGFR2^{-}/osteocalcin^{-}/colagen II^{-} cells. By incubating these cells in specific differentiation media, adipocytes and osteoblasts were obtained, demonstrating their multipotent capacity (figures 5 and 6).

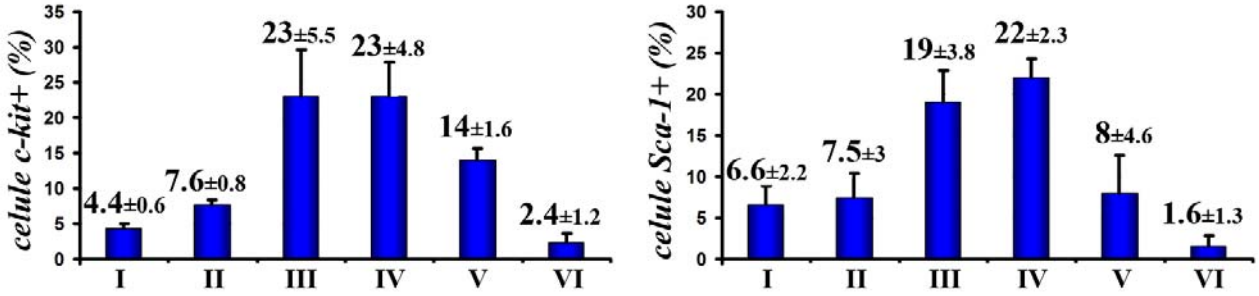

Figure 4: Overall representation of flow cytometry data showing the average percentages of c-kit+ and Sca-1+ cells within each fraction obtained after Percoll gradient separation of bone marrow aspirate.

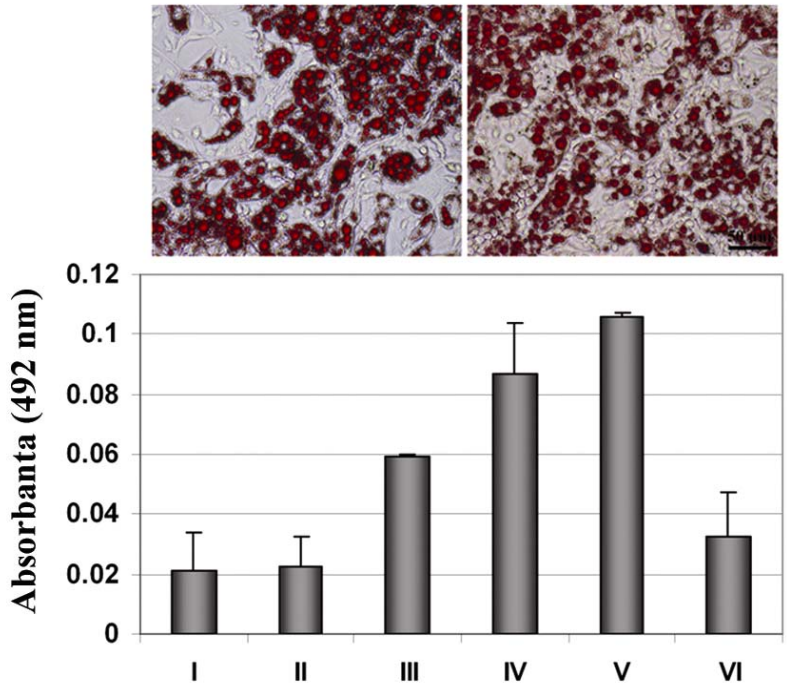

Figure 5: Spectrophotometric quantification of lipid accumulation in the six fractions after culturing the cells in adipogenic medium. The upper panel depicts a representative picture of Oil Red staining in fractions III and IV. Fraction V, despite the massive lipids accumulation, is not enriched in progenitor cells; the staining is most likely due to the presence of preadipocytes.

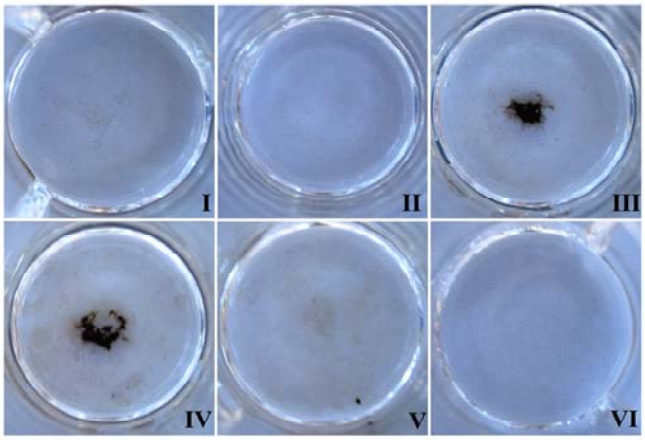

Figure 6: Light microscopy of von Kossa staining in the six fractions after cultivation in osteogenic medium. It can be noticed that fractions III and IV, but not fraction V (that contained the majority of the cells), were able to generate osteoblasts in appropriate conditions.

II.2. Isolation of mesenchymal stem cells form haematogenous bone marrow

In parallel with the method described above, a homogenous population of mouse MSC was obtained by maintaining the cells in culture for a long period of time. After approximately eight weeks, the cells a homogeneous culture with fibroblast-like appearance and highly proliferative. RT-PCR (Figure 7a) showed the presence of expression of Sca-1 and CD105 (endoglin) stem cell markers and the lack of c-kit marker, which suggested the depletion of haematopoietic progenitor cells. Another characteristic of these cells was the presence of vimentin and nestin intermediate filaments. Knowing that the presence of nestin filaments is specific to early progenitor cells with migratory capacity, the expression of nestin, associated with vimentin expression (Figure 7b) suggested for these cells a possible role in tissue regeneration.

Characterization of these cells was complemented by studies of differentiation into multiple cell types, such as adipocytes, osteoblasts and chondrocytes (Figure 8). These experiments showed their multipotent character, which was unaltered over several passages. This culture was subsequently used in studies of differentiation towards muscle cells. The data were presented in Chapter III of the thesis.

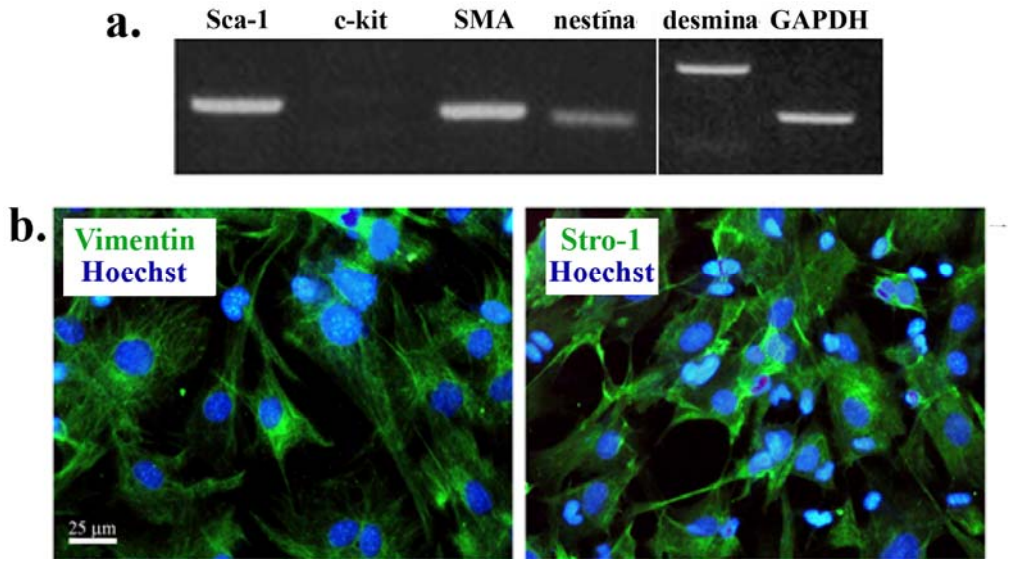

Figure 3. (a) RT-PCR showing the presence of Sca-1, smooth muscle actin (SMA), nestin, and desmin, and the lack of the hematopoietic stem cells marker c-kit; (b) Imunocitochemistry depicting the presence of the intermediary filament vimentin and of the stromal cells marker Stro-1 in all cells in the culture of MSC.

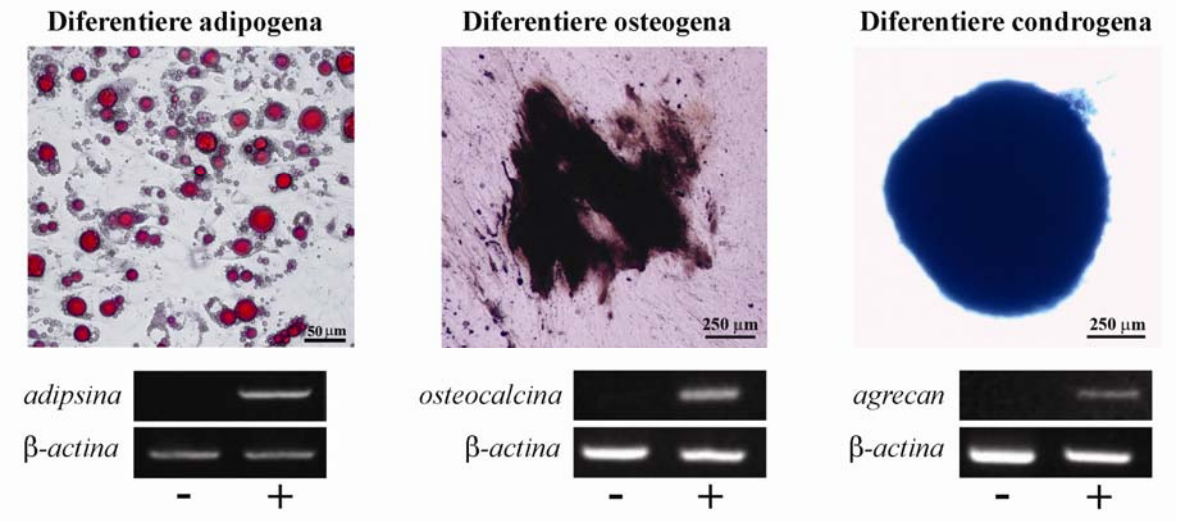

Figure 8: Characterization of MSC multipotency: Adipogenic differentiation (left panel) is shown by Oil Red staining and activation of adipsin gene expression. Osteogenic differentiation (middle panel) was confirmed by von Kossa staining and activation of osteocalcin gene expression. Chondrogenic differentiation (right panel) was confirmed by Alcian Blue staining and activation of aggrecan gene expression in differentiated cells.

III. Studies of mesenchymal stem cells differentiation

In order to assess the differentiation capacity toward CMC of MSC, the demethylating compound 5-azacytidine, known for its ability to enhance the differentiation of embryonic stem cells towards CMC was used.

A point of interest was the action of 5-azacytidine on multipotent stem cells, namely the ability of this compound to affect the ability of MSC to differentiate into multiple cell lines. The results showed that cells treated with 5-azacytidine gradually lost their ability to differentiate towards adipocytes and osteoblasts when they were incubated in specific differentiation conditions. An unexpected result was the increase of condrogenic differentiation potential induced by 5-azacytidine treatment. The conclusion of this study was that MSC keep their multipotency after the first exposure to 5-azacytidine, but their capacity to differentiate into multiple cell lines is gradually reduced with each exposure, while their capacity to generate chondrocytes is increased (Figure 9).

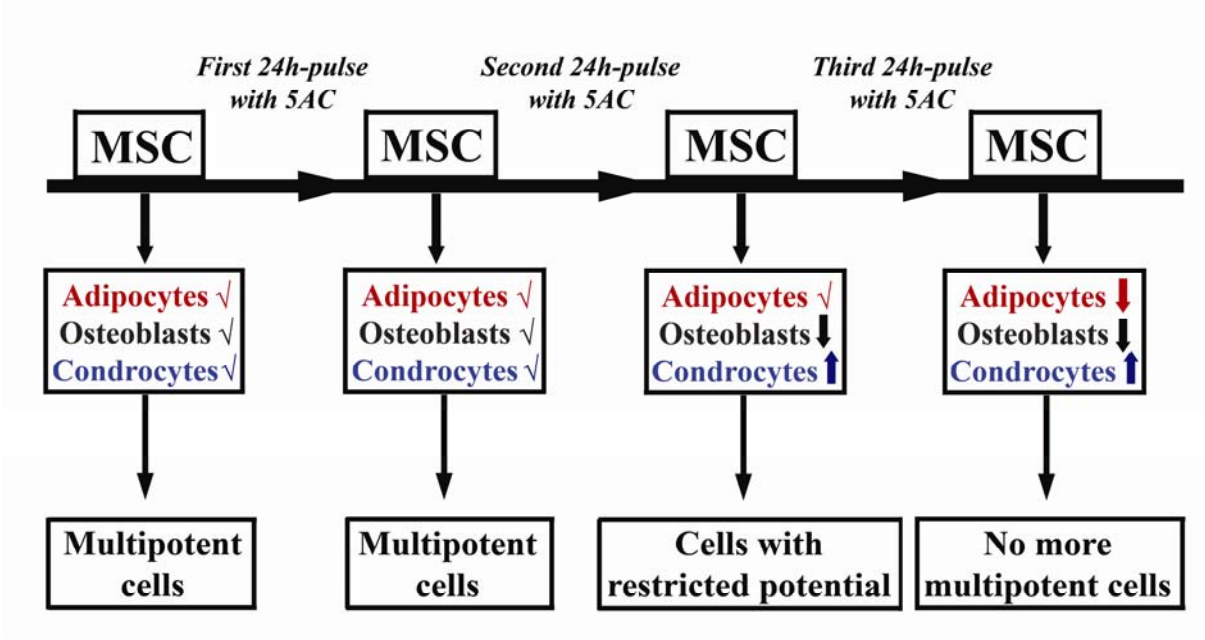

Figure 9: The effect of 5-azacytidine pulses on the multipotency of MSCs. The multipotency of MSC becomes restricted after exposure to more than one pulse of 5-azacytidine. After two or three pulses with 5-azacytidine, their capacity to differentiate into chondrocytes is considerably increased.

In the same time, the ability of 5-azacytidine to induce differentiation of MSC towards a cardiac muscle phenotype was followed. As shown in Figures 10 and 11, except for some muscle-specific genes (α-actin cardiac and L-type calcium channel), the expression of any of the genes involved in differentiation of cardiac muscle induced by this treatment. However, 5-azacytidine induced the expression of some skeletal muscle specific genes, which promoted the differentiation of MSC into myoblasts when incubated in appropriate conditions (Figure 12). In conclusion, 5-azacitidine treatment could favour MSC differentiation into cardiac cells, if specific factors that could affect the completion of the differentiation process into CMC mature and functional differentiation would be provided.

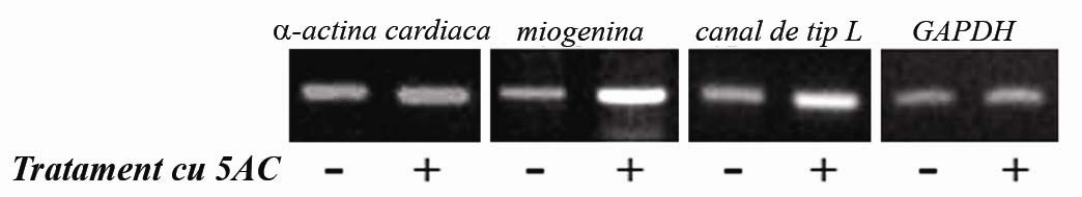

Figure 10: RT-PCR illustrating the expression of several muscle-specific genes that are elevated in MSC after one pulse with 5-azacytidine.

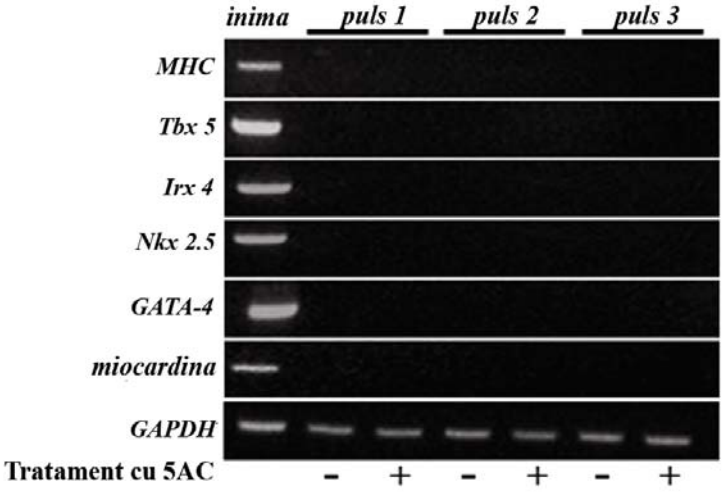

Figure 11: RT-PCR illustrating that the expression levels of genes specifically involved in cardiac differentiation are not increased in MSC by 5-azacytidine treatment.

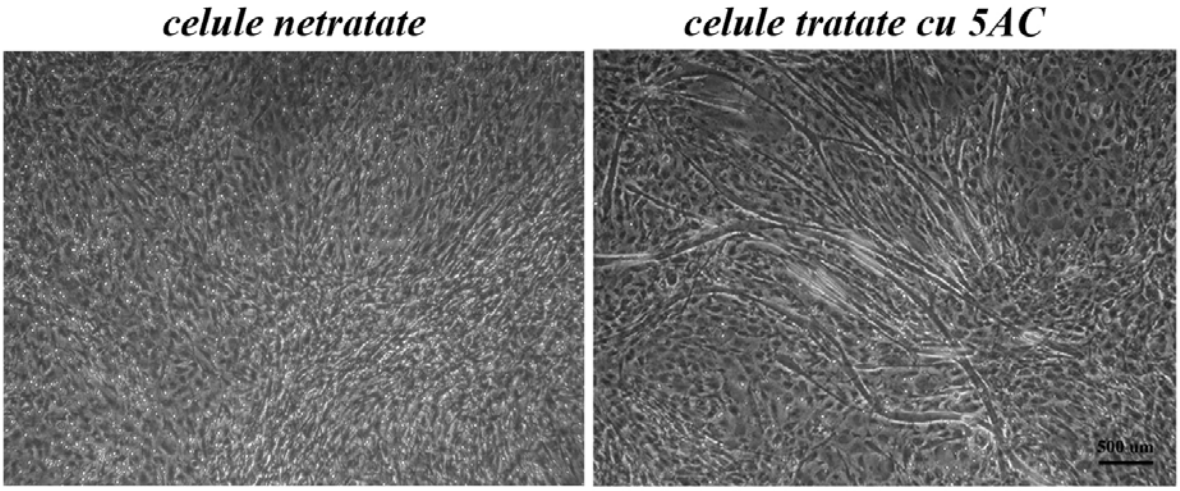

Figure 12: Phase-contrast microscopy image illustrating the appearance of myotubes in cultures of MSC incubated under serum deprivation conditions after three previous pulses with 5-azacytidine.

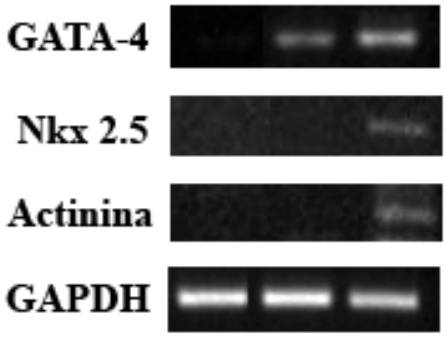
Following these observations, we found that 5-azacitidine treatment associated with direct contact with cardiac muscle cells may have a beneficial effect on differentiation into CMC of a stromal cell population. Thus, the changes in marrow stromal cells through direct contact with cardiac muscle cells combined with 5-azacitidine treatment were studied. The results showed that the two factors resulted in triggering the expression of cardiac specific transcription factors in mouse bone marrow stromal cells such as GATA-4 and Nkx2.5 (Figure 13).



CSA	+	+	+
CMC	-	+	+
5AC	-	-	+

Figure 13: RT-PCR showing induction of cardiac markers gene expression in cells treated with 5-azacitidine after 1 week of coculture with CMC. It can be noticed that the cumulative effect of the two conditions (treatment with 5-azacitidine and direct contact between stromal cells and CMC) is superior to simple contact between the two cell types.

Moreover, it was observed that expression of the latter was induced only if both differentiation stimuli were applied. In addition, actinin expression was induced, indicating differentiation towards to a striated muscle phenotype. Furthermore, the results of double chambers coculture experiments showed that combining 5-azacitidine treatment and soluble factors released from ischemic myocardium resulted in increased differentiation of bone marrow cells towards a cardiac phenotype. Thus, addition of exposure to 5-azacytidine to signals from the ischemic myocardial tissue triggered the transcription of key factors involved in cardiac differentiation, such as: muscle specific actin and striated type actinin, desmin, GATA-4, Nkx2.5 and L-type calcium channel (figure 14). Thus, it can be concluded that the initiation of differentiation induced by demethylation of certain genes is supported by the effect of some cardiac soluble factors that are able to complete this process.

IV. Identification of some paracrine factors secreted by normal and hypoxic mesenchymal stem cells

Recent reports on clinical trial results showed that the beneficial effects of stem cell transplantation in myocardial infarction is transient, suggesting a paracrine effect exerted by the transplanted cells through the secretion of cardioprotective and angiogenic factors. Thus, in the last part of the thesis the anti-apoptotic effect of soluble factors released by MSC on cardiac muscle cells was studied and some factors released by MSC in normal and hypoxic conditions were identified. A particularly important observation was the MSC capacity to adapt and survive in hypoxic conditions, as demonstrated by the resistance of these cells to the hypoxic conditions induced apoptosis (Figure 15).

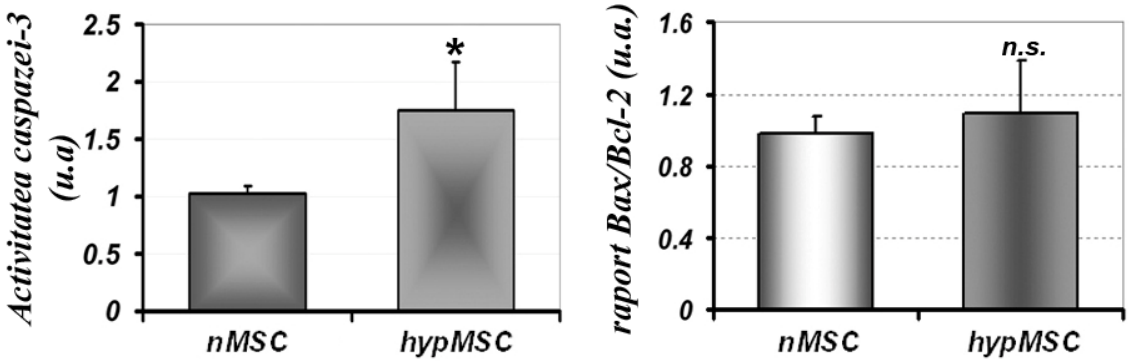

Figure 15: MSC in ischemic conditions: the graph on the left side of the figure shows a slight increase in the activity of caspase-3, while the ratio of pro-apoptotic protein Bax and anti-apoptotic protein Bcl-2 gene expression, as determined by quantitative PCR, remained unchanged (chart on the right).

MSC resistance to hypoxia-induced apoptosis is particularly important for their survival in the ischemic myocardium, where the blood vessels needed to ensure adequate oxygenation are lacking.

Our results sowed that MSC derived conditioned medium had cardioprotective effects on hypoxic CMC. Thus, the presence of MSC derived conditioned medium prevented the trigger of the apoptotic process induced by hypoxia in CMC (Figure 16) by preserving the integrity of mitochondrial membrane. By concluding, MSC transplanted in hypoxic myocardium *in vivo* might have an important contribution to the survival of the CMC affected by hypoxia and oxidative stress during reperfusion.

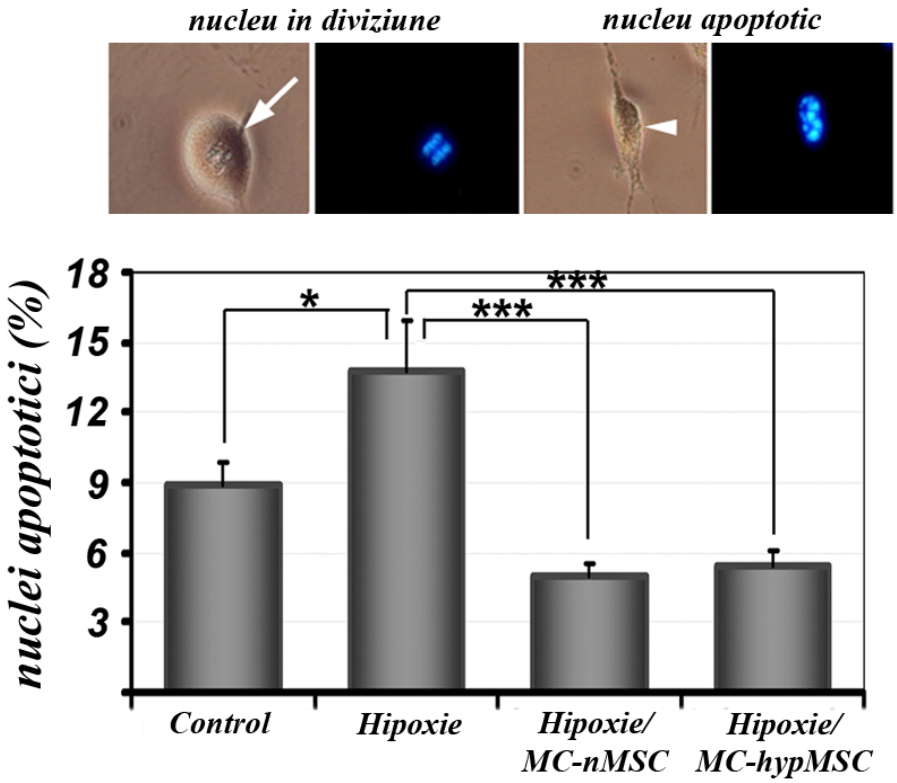

Figure 16: Quantitative determination of apoptosis in cardiac myocytes after exposure to hypoxia in the presence and absence of conditioned medium collected from MSC. The chart shoes the percentages of apoptotic nuclei determined by Hoechst staining. Images of apoptotic versus mitotic nuclei can be seen above.

Moreover, conditioned medium harvested from both normal and hypoxic MSC had similar effects, which suggested that MSC maintain their cardioprotective properties in hypoxic conditions.

Assessing the composition of MSC-conditioned medium showed that these cells are able to retain their ability to synthesize and release some cardioprotective factors such as cytokines and microRNAs. Several cytokines secreted by both normal and hypoxic MSC were identified, four of which were found in similar quantities the MSC incubated in hypoxia compared to the control: TIMP-1, MCP-1, SDF-1α and IL1ra (Figure 17). According to the literature, these factors could be responsible, at least in partially, of the cardioprotective effect exerted by the presence of MSC in the ischemic myocardium, either due to their anti-apoptotic action or by inducing angiogenesis, which is important for restoring the oxygen and nutrients supply.

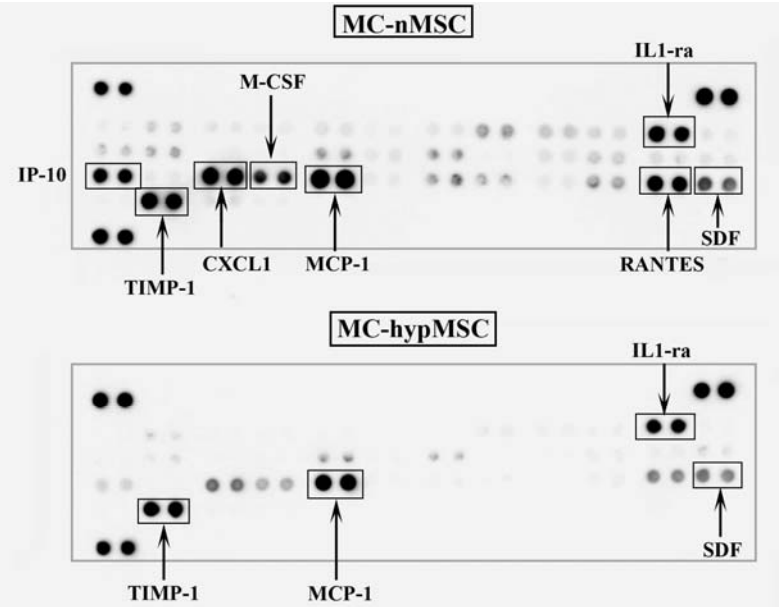

Figure 17: Citokine array showing the composition of normoxic MSC conditioned medium (upper panel) comparing to hypoxic MSC conditioned medium (lower panel).

In addition to these molecules, it appears that the transfer of genetic information between MSC and damaged cells is an important mechanism, which might have a repairing effect on injured myocardium. Thus, the hypoxic MSC derived conditioned medium contained an increased quantity of microRNAs 199a and 125b, known for their anti-apoptotic action (Figures 18 and 19).

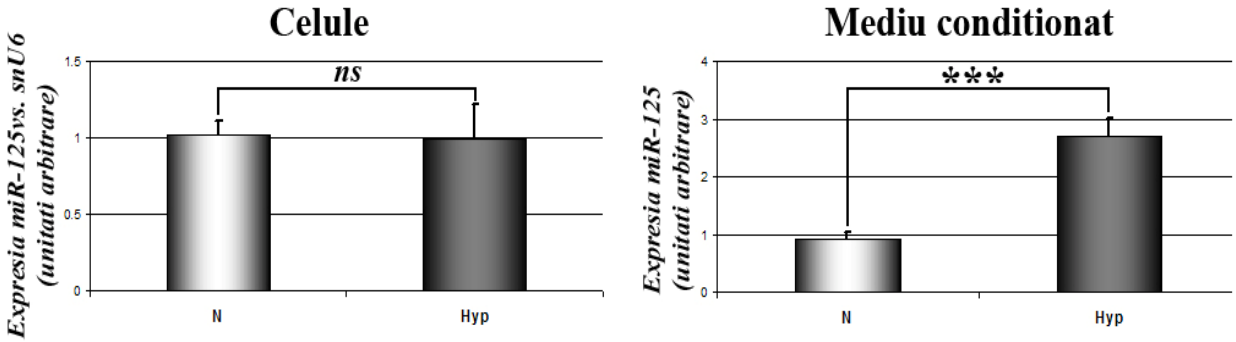

*Figure 18: Quantitative PCR showing microRNA-125 expression in normal versus hypoxic MSC (left chart) and the extracellular medium harvested from cells maintained in normal comparing to hypoxic conditions (right chart) (*** p <0.0005).*

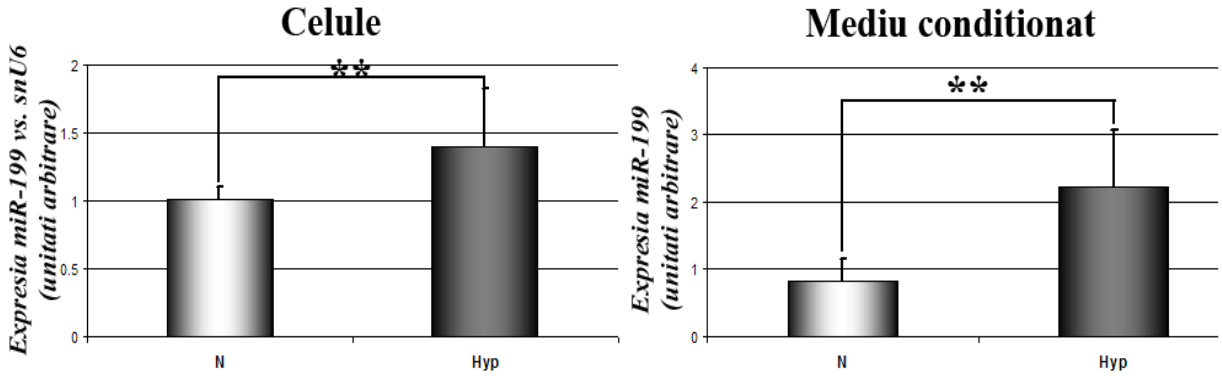

*Figura 19: Quantitative PCR showing microRNA-199a expression in normal versus hypoxic MSC (left chart) and the extracellular medium harvested from cells maintained in normal comparing to hypoxic conditions (right chart)(** $p<0.005$).*

In conclusion, the composition of MSC conditioned medium consists in a mixture of factors with either anti-apoptotic effect (TIMP-1, MCP-1, miR-199a, miR-125b), inhibitory for fibroblasts proliferation (IL1ra) or angiogenic (SDF-1α). The presence of these cardioprotective factors in MSC secretion may be responsible for anti-apoptotic effect on CMC hypoxic conditions observed in our experiments.

Conclusions

The data obtained during the doctoral stage were published in international journals with ISI impact factor and were presented at national and international scientific meetings as oral presentations or posters. Briefly, the main results were as follows:

- It has been shown that the main factor that triggers apoptosis in CMC after myocardial infarction is represented by the exogenous oxidants brought at the site of injury during reperfusion;
- A method for obtaining a population of progenitor cells obtained from bone marrow aspirate by centrifugation on Percoll discontinuous gradient was developed;
- Homogenous MSC cultures meeting the standards required by the International Society for Cellular Transplant were obtained;
- The effect of 5-azacytidine induced demethylation on the multipotency of MSC was pointed out;
- The beneficial cumulative effect of 5-azacytidine and soluble factors released by ischemic myocardium on MSC cardiac differentiation was demonstrated;

- The anti-apoptotic effect of factors released from normal and hypoxic MSC on hypoxic CMC was shown;
- Anti-apoptotic, anti-fibrotic and pro-angiogenic factors were identified in normal and hypoxic MSC derived conditioned medium.

PN-III-P1-1.1-TE-2019-2044 (acronim A2A)
„Peptide derivate din apolipoproteina A-II cu potential terapeutic in ateroscleroza”

REZUMAT RAPORT ŞTIINŢIFIC
privind implementarea proiectului in perioada 15/09/2020– 30/11/2022

In cadrul proiectului de cercetare **PN-III-P1-1.1-TE-2019-2044 (acronim A2A)** cu titlul: „Peptide derivate din apolipoproteina A-II cu potential terapeutic in ateroscleroza” au fost realizate toate obiectivele si activităţile planificate in cadrul proiectului:

Etapa 1 (15/09/2020 - 31/12/2020) - Obţinerea plasmidelor recombinante pentru obtinerea adenovirusurilor care codifică diverse peptide derivate din apoA-II

Activitatea 1.1 - Obţinerea plasmidelor recombinante care codifică peptide derivate din ApoA-II pt amplificarea adenovirusurilor specifice au fost efectuate in mai multe etape:
(i) recombinarea constructilor care codifica pt apoA-II în bacterii BJ5193 care conţin pAdEasy-1 prin transformarea chimică în bacterii;
(ii) selectarea clonelor recombinante pozitive prin PCR;
(iii) amplificarea clonelor recombinante pozitive selectate folosind bacterii DH5a.

Etapa 2 (01/01/2021 - 31/12/2021) **-** Generarea de adenovirusuri recombinante care peptide derivate apoA-II cu cisteina (SSCH1, SSCH2, SSCH3, SSCH1H2, SSCH2H3), precum apoA-II cu lungime completa
Activitatea 2.1 - Generarea de adenovirusuri recombinante care peptide derivate apoA-II cu precum apoA-II cu lungime comleta
Activitatea 2.2 - Amplificarea adenovirusurilor recombinante care peptide derivate apoA-II cu precum apoA-II cu lungime completa
Activitatea 2.3 - Purificarea adenovirusurilor care peptidele derivate din apoA-II,
Activitatea 2.4 - Titrarea adenovirusurilor care peptidele derivate din apoA-II.

Etapa 3 (01/01/2022 - 30/11/2022) - Evaluarea capacităţii peptidelor derivate din apoA-II de a regresa placa aterosclerotice folosind un model murin de ateroscleroză.
Activitatea 3.1 - Administrarea dietei bogată în grăsimi la şoarecii apoE deficienti,
Activitatea 3.2 - Transductia soarecilor cu diferite forme truncate de apoA-II,
Activitatea 3.3 - Evaluarea nivelului total/HDL/LDL-colesterol şi trigliceride in probele de sânge de la şoarecii transduşi,
Activitatea 3.4 - Caracterizarea lipoproteinelor de la şoarecii transduşi cu formele truncate ale apoA-II,
Activitatea 3.5 – Testarea capacităţii de eflux a colesterolului de la şoarecii transduşi cu formele truncate ale apoA-II,
Activitatea 3.6 - Analiza evoluţiei plăcilor aterosclerotice la şoarecii apoE deficienti transdusi cu forme truncate ale apoA-II.

Rezumat Raport Etapa 1. Prin clonare moleculara, au fost obţinuţi şase construcţi conţinând diferite fragmente ale genei apoA-II inserate în vectorul pADTrack. Construcţii obţinuţi conţin secvenţa semnal (SS), aminoacidul cisteina din poziţia 6 (C) şi câte unul sau doua helixuri (H1, H2, H3) ale apoA-II. Aceşti construcţi au fost notaţi astfel: 1.SS-C-H1, 2.SS-C-H2, 3.SS-C-H3, 4.SS-C-H1H2, 5.SS-C-H2H3.

Etapele de obţinere a construcţilor cu fragmente apoA-II inserate în pADTrack au fost urmatoarele:

1. Obţinerea fragmentelor apoA-II s-a realizat prin overlapping PCR. Fragmentele de ADN amplificate prin PCR au fost separate prin electroforeza in gel de agaroză 1% colorat cu MidoriGreen. Benzile corespunzătoare fragmentelor apoA-II au fost excizate din gelul de agaroză, iar ADN a fost izolat si purificat din gel folosind un kit Promega (Wizard SV gel and PCR Clean-up System).
2. Clivarea capetelor ADN cu enzimele Kpn I si Xho I
3. Ligarea insertului (fragment apoA-II) în vectorul pADTrack folosind T4 ADN ligază
4. Selecţia clonelor care au integrat insertul (fragment apoA-II) în vectorul pADTrack

Fragmentele apoA-II clonate în pADTrack au fost utilizate pt recombinare in bacterii competente BJ5183.Recombinarea ADN in bacterii competente BJ5183 s-a realizat cu kitul Mix&Go Transformation. Simultan cu cele cinci fragmente apoA-II, a fost recombinat şi apoA-II total (SS-C-H1H2H3) clonat în vectorul pAD Track. Etapele recombinarii ADN au fost urmatoarele:

1. Digestia ADN cu enzima de restrictie PmeI
2. Izolarea si purificarea ADN cu fenol/cloroform/alcool izoamilic
3. Transformare bacteriana cu bacterii competente BJ5183
4. Selecţia clonelor prin „PCR negativ": PCR cu primerii pAD Track 4631F si pAD track 5616R.
5. Selecţia clonelor prin „PCR pozitiv" prin care a fost testata prezenta fiecărui fragment apoA-II.
6. Liza alcalină a culturilor bacteriene.
7. Re-transformarea ADN recombinant in bacterii competente DH5α

După confirmarea prin digestie enzimatică cu PacI şi PstI, din fiecare clona pozitiva selectata s-a realizat amplificarea ADN in bacterii DH5a si s-a obtinut o cantitate mare de ADN.

Rezumat Raport Etapa 2. Etapele de obţinere a adenovirusurilor recombinante care codifica peptide derivate din apoA-II au fost:

i. Recombinarea constructilor in pAdTrack cu pAdEasy-1 in bacterii BJ5183

ii. Selectarea clonelor pozitive prin PCR si digestie cu enzime de restricţie (ex: KpnI, PstI si HindIII)

iii. Impachetarea particulelor adenovirale in celule AD293.

Pentru recombinarea constructilor in pAdTrack cu pAdEasy-1, bacteriile BJAdEasy (#16399 Addgene) competente au fost preparate folosind kitul Mix&Go E.coli Transformation Kit (Zymo Research). După obtinerea ADN recombinant in pAdTrack cu pAdEasy-1, acesta a fost verificat prin PCR si digestie enzimatica. După confirmarea prin digestie enzimatică, din fiecare clona pozitiva selectata s-a realizat amplificarea ADN in bacterii DH5a si s-a obtinut o cantitate mare de ADN.

Pentru amplificarea adenovirusurilor recombinante care codifică peptide derivate din apoA-II cu cisteină precum şi apoA-II cu lungime completă, celulele AD293 au fost insamantate in flaskuri T25 si transfectate cu ADN recombinant linearizat cu enzima de restricţie PacI. Dupa 12 zile, mediul cu celule transduse a fost colectat si centrifugat. Sedimentul celular a fost resuspendat in PBS si supus unor cicluri de inghetare (in azot lichid) - dezghetare (la 37°C) succesiv de trei ori, apoi a fost trecut prin seringa (23G). Atat mediile colectate cat si sedimentele obtinute au fost adaugate peste celule AD293 (insamantate cu o zi inainte). Adenovirusurile au fost amplificate succesiv in flask-uri T75 → T175 → 5 flaskuri T175 → ≥ 25 flaskuri T175. Intrucat vectorul adenoviral utilizat in obtinerea adenovirusurilor (care codifica pentru proteina ApoA-II) produce si proteina fluorescenta verde (GFP), celulele care au produs adenovirusul au putut fi monitorizate si prin microscopie de fluorescenta. Adenovirusurile din mediu au fost precipitate utilizand sulfat de amoniu, dupa care a fost realizata purificarea adenovirusurilor prin ultracentrifugare in gradient de CsCl urmata de dializa. Celulele care au produs adenovirusurile au fost colectate, centrifugare si supuse unor cicluri consecutive inghet/dezghet. In continuare s-a efectuat purificarea adenovirusurilor prin ultracentrifugare in gradient de CsCl si dializa.

Titrarea adenovirusurilor care codifică peptidele derivate din apoA-II a fost realizata prin citometrie in flux, in urma transducerii celulelor AD293 cu dilutii seriale ale virusurilor purificate. Titrul viral al adenovirusurilor care codifică peptide derivate apoA-II cu cisteină precum şi apoA-II cu lungime completă a fost cuprins intre 1.7-4,3x1011 TU/ml. (TU=Transforming Units).

Rezumat Raport Etapa 3. Efectele transductiei cu forme truncate de apoA-II in modelul murin de ateroscleroză au fost evaluate la intervale diferite de timp: I. la timp scurt si II. la timp lung.

I. Femele apoE-/-, in varsta de 6 luni, au fost impartite in cinci loturi experimentale (n=3/grup), pentru fiecare dintre cele 4 adenovirusuri si un grup sham. Soarecii au fost injectati cu suspensie adenovirala (100 µl), intravenos, in vena laterala caudala, folosind o doza de 5x10^9 TU/ml, sau vehicul folosit pentru prepararea suspensiei virale (PBS). Titrul viral al adenovirusurilor care codifică peptide derivate din apoA-II precum şi apoA-II total a fost cuprins intre 1.7-4,3x10^{11} TU/ml. Pe parcursul intregului experiment, animalele au primit hrana si apa ad libitum, iar starea generala si greutatea acestora a fost monitorizata. La 4 zile dupa transductie si dupa 5 ore de fasting, animalele au fost anesteziate cu un cocktail de ketamina/xilazina/acepromazina (80/10/2 mg/kg corp), iar sangele a fost recoltat prin punctie intracardiaca pentru obtinerea plasmei. Ulterior, animalele au fost perfuzate intracardiac cu PBS si s-a realizat prelevarea chirurgicala a lobului hepatic stang. Tesutul hepatic a fost prelucrat pentru analiza ARN. Plasma a fost utilizata pentru urmatoarele analize: 1) determinarea valorilor colesterolului si trigliceridelor, 2) analiza expresiei apoAI si apoAII murin prin ELISA, 3) determinarea aspectului si dimensiunii particulelor HDL in fractii prin microscopie electronica de transmisie si Nanosizer si 4) determinarea activitatii PON-1 in fractii.

Masculi apoE-/-, in varsta de 4 luni, au fost impartiti in cinci loturi experimentale (n=4/grup), pentru fiecare dintre cele 4 adenovirusuri si un grup sham. Soarecii au fost injectati cu suspensie adenovirala (100 µl), intravenos, in vena laterala caudala, folosind doze de 10^8 TU/ml, 5*10^8 TU/ml, 10^9 TU/ml, 5x10^9 TU/ml si 10^10 TU/ml sau vehicul folosit pentru prepararea suspensiei virale (PBS). Pe parcursul experimentului, animalele au primit hrana normal si apa ad libitum, iar starea generala si greutatea acestora a fost monitorizata. La 7 zile dupa transductie, animalele au fost anesteziate cu un cocktail de ketamina/xilazina/acepromazina (80/10/2 mg/kg corp) si sangele a fost recoltat prin punctie intracardiaca pt obtinerea plasmei. Ulterior, animalele au fost perfuzate intracardiac cu PBS si s-a realizat prelevarea chirurgicala a ficatului. Acesta a fost utilizat pt analiza IVIS a transductiei adenovirale. Plasma a fost utilizata pt determinarea valorilor colesterolului si trigliceridelor si pt analiza expresiei apoA-I murin prin ELISA.

Ficatul soarecilor apoE-/- injectati cu adenovirus care codifica apoA-II si forme truncate ale apoA-II a fost transdus cu succes (in special in cazul soarecilor transdusi cu apoA-II se observa benzi de ADN bine conturate), iar adenovirusurile injectate sunt pure, ADN extras fiind amplificat cu primerii specifici fiecarui fragment al apoA-II (cu exceptia adenovirusului care codifica fragmentul H1 al apoA-II).

Rezultatele au aratat ca cea mai mare concentratie de apoAI murin se gaseste in plasma soarecilor apoE-/- injectati cu 5*10^9 TU/ml de adenovirus care codifica apoA-II, concentratia plasmatica cea mai redusa de apoAI murin fiind la soarecii injectati cu 10^8 TU/ml de adenovirus. In urma transductiei adenovirale, concentratia de triglyceride si de colesterol total in plasma a crescut la toate grupele de soareci, comparativ cu grupul control. Imaginile de microscopie electronica de transmisie a HDL din fractia 8 de lipoproteine izolata de la soarecii apoE-/- transdusi cu adenovirus care codifica apoA-II si fragmentul H3 al apoA-II, la 4 zile post-transductie. 5 µl din au aratat o heterogenitate in ceea ce priveste aspectul si dimensiunea particulelor HDL la cele 3 grupe de soareci analizati.

Cuantificarea expresiei proteice a apoA-II murin in plasma de la soarecii apoE-/- transdusi cu adenovirus care codifica apoA-II si forme truncate ale apoA-II a fost realizata prin ELISA de tip sandwich, la 4 zile post-transductie, utilizand un kit specific. S-a observat ca cele mai mari concentratii ale apoA-II murin au fost intalnite la soarecii injectati cu adenovirus care codifica fragmentul H3 al apoA-II, in timp ce concentratia minima este atribuita soarecilor transdusi cu adenovirus care codifica fragmentul H1 al apoA-II.

Concentratia de trigliceride in fractii izolate de la soarecii apoE-/- transdusi cu adenovirus care codifica apoA-II si forme truncate ale apoA-II a fost determinata prin utilizarea unui kit specific de dozare, la 4 zile post-transductie. In urma transductiei adenovirale, concentratia de trigliceride a prezentat valori maxime in fractia 9 la soarecii din grupul H1 si sham. De asemenea, au fost observate valori crescute ale concentratiei de colesterol in fractiile de VLDL la toate grupele de soareci, in special la grupul H1. Valorile maxime ale concentratiei de colesterol in fractiile de HDL au fost observate in fractia 8 la toate grupele de soareci, la grupul H2 si grupul H3 inregistrandu-se cele mai ridicate valori.

Activitatea PON-1 a fost determinata in fractii izolate de la soarecii apoE-/- transdusi cu adenovirus care codifica apoA-II si forme truncate ale apoA-II. S-a observat o initiere a activitatii PON-1 in fractii incepand cu fractia 7 (la grupul de soareci H1, H3 si A2) sau fractia 8 (grupul de soareci H2 si sham), cu un

maxim de activitate in fractia 9 si un minim de activitate in fractia 11 pentru toate grupele de soareci. De asemenea, PON-1 este cea mai activa in grupele de soareci H3 si H1, la polul opus situandu-se grupele de soareci H2 si A2. Ptoteinele apoA-II precum si fragmentele H1 si H2 derivate din apoA-II au fost vizualizate pe gel de poliacrilamida 15% prin coloratie Pierce Silver. Au fost observate benzi proteice corespunzatoare fragmentelor H1 si H2 ale apoA-II in fractia 10, avand masa moleculara de pana in 10 kDa, precum si benzi proteice corespunzatoare apoA-II in fractiile 9-12, cu masa moleculara cuprinsa in intervalul 15-20 kDa.

II. Femele apoE-/-, in varsta de 3 luni, au fost impartite in cinci loturi experimentale (n=7/grup), pentru fiecare dintre cele 4 adenovirusuri si un grup sham. Soarecii au fost injectati saptamanal, timp de trei saptamani, cu suspensie adenovirala (100 µl), intravenos, in vena laterala caudala, folosind doza de 5x10^9 TU/ml, sau cu vehicul folosit pt prepararea suspensiei virale (PBS). Pe parcursul intregului experiment, animalele au primit hrana si apa *ad libitum*, iar starea generala si greutatea acestora a fost monitorizata. Dupa transductie, a fost realizata saptamanal dozarea de colesterol total si de trigliceride in plasma la fiecare 3 zile respectiv 6 zile dupa fiecare injectie. Pentru aceasta, de la fiecare animal s-a recoltat un volum de sange de ~ 75 µl prin tehnica de ciupire a cozii (tail snip), inainte de transductie pentru timpul 0, iar dupa transductie, la 3 si respectiv 6 zile dupa fiecare injectie. La 3 saptamani de la prima transductie si dupa 5 ore de fasting, animalele au fost anesteziate cu un cocktail de ketamina/xilazina/acepromazina (80/10/2 mg/kg corp) si sangele a fost recoltat prin punctie intracardiaca pentru obtinere de plasma. Plasma a fost utilizata pentru determinarea valorilor colesterolului si trigliceridelor.

Concentratia de trigliceride in plasma soarecilor apoE-/- transdusi cu adenovirus care codifica apoA-II si forme truncate ale apoA-II, a fost determinata prin utilizarea unui kit specific de dozare, la fiecare 3, respectiv 6 zile post-transductie. Valorile maxime ale concentratiei trigliceridelor in plasma au fost inregistrate in urma administrarii celei de-a treia doze adenovirale, respectiv in ziua 15 post-transductie, la toate grupele de soareci, in timp ce valorile minime, au fost observate in ziua 17 post-transductie. Concentratia de trigliceride in fractii izolate din plasma soarecilor apoE-/- transdusi cu adenovirus care codifica apoA-II si forme truncate ale apoA-II, determinata prin utilizarea unui kit specific de dozare, la 24 zile post-transductie. Post-transductie, concentratia de triglyceride a prezeintat un peak in fractia 6 la grupele H2 si A2, in timp ce la grupul H3 acest peak se afla in fractia 7, iar la grupul H1 este in fractia 10.

Concentratia de colesterol in plasma soarecilor apoE-/- transdusi cu adenovirus care codifica apoA-II si forme truncate ale apoA-II, a fost determinata prin utilizarea unui kit specific de dozare, la fiecare 3, respectiv 6 zile post-transductie. Valorile maxime ale concentratiei de colesterol in plasma au fost inregistrate in ziua 14 post-transductie la grupul H1, respectiv in ziua 17 la grupurile H2 si H3. La 24 de zile post-transductie, toate grupele de soareci au prezentat valori minime ale concentratiei de colesterol, dar mai mari decat cele de la momentul zero. La grupul A2, in intervalul de zile 10-17 au fost observate valori mai reduse ale concentratiei de colesterol fata de celelalte grupe de soareci. Concentratia de colesterol in fractiile VLDL la soarecii apoE-/- transdusi cu adenovirus care codifica apoA-II si forme truncate ale apoA-II, a fost determinata prin utilizarea unui kit specific de dozare, la fiecare 3, respectiv 6 zile post-transductie. Concentratiile de colesterol in fractiile VLDL au fost uniforme pt grupele de soareci utilizate in experiment, exceptie facand grupul A2, unde valorile inregistrate pt concentratia de colesterol au fost mai ridicate fata de restul grupelor. Concentratia de colesterol in fractiile HDL la soarecii apoE-/- transdusi cu adenovirus care codifica apoA-II si forme truncate ale apoA-II, au fost determinata prin utilizarea unui kit specific de dozare, la fiecare 3, respectiv 6 zile post-transductie. In fractiile 8 si 9, concentratiile de colesterol au prezentat valori minime pt grupele de soareci H1, H2 si H3. La grupul A2 concentratiile de colesterol au fost mai ridicate decat la restul grupelor in fractiile de HDL.

De asemenea, a fost evaluat potentialul formelor truncate ale apoA-II de a reduce leziunile aterosclerotice prin promovarea efluxului de colesterol la soareci apoE-/- injectati cu adenovirus care codifica apoA-II si forme truncate ale apoA-II. Cuantificarea leziunilor a aratat o reducere semnificativa a suprafetei lezionale la animalele transduse cu adenovirus care codifica fragmentul H1 al apoA-II comparativ cu grupul control. Scaderi semnificative s-au obtinut si pt grupurile de animale H2 si H3, comparativ cu grupul control.

Toate rezultatele obtinute reprezinta materialul pt un articol stiintific care este in pregatire pt publicare.

Diseminarea rezultatelor

Rezultatele obţinute in cadrul proiectului au fost prezentate la următoarele manifestări ştiinţifice:

- **„Generation of recombinant adenoviruses encoding ApoA-II**", autori Gabriela Florea, Irina F. Tudorache, Violeta G. Trusca, Laura Moise, Madalina Fenyo, Anca V. Gafencu, poster prezentat la 45th European Lipoprptein Club (ELC) Meeting, Tutzing, Germany, 04-08.09.2022
- "**Generation of recombinant adenoviruses encoding ApoA-II**", Gabriela Florea, Irina F. Tudorache, Violeta G. Trusca, Anca V. Gafencu, poster prezentat la „A 23 a Conferinta Internationala: Materials, Methods & Technologies", organizata in Burgas, Bulgaria in perioada 19-22 August 2021

Résumé

Importance de l'étude

La compréhension des mécanismes qui conduisent à la différenciation de cellules souches est l'objet principal de nombreuses études. L'accessibilité de l'ADN à des facteurs de transcription dépend de la structure de la chromatine et de le degré de compactage. Analyses récentes des modifications épigénétiques dans les cellules souches humaines et murines ont fourni de nouvelles données sur les propriétés des cellules souches pluripotentes et de leur capacité de différenciation. Ces mécanismes conduisent à une hiérarchie de la transcription qui est induite par des facteurs de transcription et sont conçus pour contrôler l'expression du gène sans altérer l' ADN. La capacité des cellules souches multipotentes diminue avec le temps en raison de la répression de certains gènes qui ont une "signature" épigénétique. Les gènes actifs dans les cellules souches sont rendues silencieux progressivement avec le passage de leurs ancêtres, et un autre sous-ensemble de gènes spécifiques de tissus sont activés. Cette progression est obtenue par une expression sélective de facteurs de transcription qui reconnaissent et interagissent avec diverses modifications épigénétiques de la chromatine. A la suite de ces événements, la chromatine devient accessible pour la transcription dans certaines régions, ce qui permet la différenciation spatiale et temporelle nécessaire pour les cellules souches de commande. Par exemple, la protéine HP1 (protéine de l'hétérochromatine1) change sa distribution d'une localisation dispersée dans des cellules souches embryonnaires a l’une plus concentrée dans loci distincts lors de la différenciation cellulaire. L'acétylation des histones a été considérée comme un phénomène en corrélation avec une conformation de la chromatine ouverte qui a permis l'expression de différents gènes impliqués dans la différenciation. Actuellement il est observé que dans l'état acétylé, des nombreux gènes sont réprimés et donc la différenciation à une lignée cellulaire spécifique est bloquée, en les maintienent dans l'état pluripotent. Manipulation de l’activité des histone déacétylase pourrait être un outil utile pour générer des populations de cellules spécifiques dans le but de les utiliser dans la transplantation.

Découvrir les modèles d'acétylation ("*acetylation signature*") impliqués dans la différenciation des cellules souches de différents types de cellules, ouvrant de nouvelles opportunités à l'interface entre la chimie et la biologie des cellules souches, et peuvent fournir des informations précieuses pour améliorer les applications des cellules souches dans l'ingénierie tissulaire et la médecine régénérative.

Dans ce contexte, **l' objectif de cette thèse** est d'étudier le rôle de l'acétylation des histones dans la différenciation des cellules progénitrices endothéliales par l'analyse de l'expression de marqueurs génétiques différents et des facteurs de transcription qui régulent l'activité de ces gènes. En outre, les études portant sur l'effet de l'acétylation sur le processus de cellules progénitrices endothéliales dans la néovascularisation *in vitro*.

La thèse est divisée en deux grandes parties : Partie I - L'état actuel des connaissances et de la Partie II - Contributions originales.

La première partie présente l'état actuel des connaissances et est organisé en trois sections.

Sous-chapitre I présent des notions sur les caractéristiques et les propriétés des cellules souches. Dans ce chapitre est présenté le modèle cellulaire utilisé, représenté par les cellules progénitrices endothéliales et leurs applications cliniques potentielles.

Sous-chapitre II fait un aperçu des principales modifications épigénétiques. Il décrit les mécanismes d'action de ces changements et les enzymes impliquées dans leur mise en œuvre. Également dans cette section est décrit le rôle des modifications épigénétiques dans la différenciation des cellules souches à diverses lignées cellulaires.

Sous-chapitre III décrit les mécanismes des acétylation des histones et leur rôle dans la différenciation des cellules souches. Ce chapitre présente les principales catégories d' histone acétyltransférase et les histones désacétylases , les mécanismes d'action de l'acétylation de l'histone et l'influence de l'acétylation sur la différenciation de cellules progénitrices endothéliales.

Dans la deuxième partie - « Contributions originales » sont présentés les résultats d'expériences visant à étudier le rôle de l'acétylation des histones dans la différenciation des cellules progénitrices endothéliales et la capacité de la néovascularisation *in vitro*.

Chapitre II.2 - " Matériels et Méthodes " décrit les principaux matériaux et techniques utilisés dans les expériences, y compris de nombreuses techniques et de la biologie cellulaire et moléculaire: PCR en temps réel, Western blot, cytométrie en flux, la microscopie électronique à

transmission et à balayage, immunocytochimie et immunohistochimie, méthodes colorimétrique et fluorimétriques.

Chapitre II.3 - " Résultats et discussion " présente les principaux résultats originaux obtenus dans les études.

Résultats et discussion

La compréhension des mécanismes qui conduisent à la différenciation de cellules souches est l'objet principal de nombreuses études. Analyses récentes des modifications épigénétiques dans les cellules souches humaines et murines ont fourni de nouvelles données sur les propriétés des cellules souches pluripotentes et de leur capacité de différenciation. Ces mécanismes conduisent à une hiérarchie de la transcription qui est induite par des facteurs de transcription qui sont destinés à contrôler l'expression de gènes sans modifier la structure de l'ADN. L'acétylation des histones est considérée comme un phénomène en corrélation avec une conformation de la chromatine ouverte, permettant l' expression de différents gènes impliqués dans la différenciation. Actuellement c'est observé que dans l'état acétylé, de nombreux gènes sont réprimés et donc la différenciation à une lignée cellulaire spécifique est bloqué, avec le maintien de l'état pluripotent.

Dans cet étude, nous avons montré que le sang de cordon ombilical contient une riche population de cellules progénitrices endothéliales avec un profil de l'immunophénotype caractéristique: CD31, CD34, CD133, CD144, CD146, VEGFR2. L'analyse moléculaire des cellules obtenues à partir de sang de cordon ombilical a montré que dans ces cellules sont exprimés a la fois les gènes impliqués dans la morphogenèse cardiovasculaire, des gènes pour des facteurs de transcription GATA2, GATA3, GATA4, et les gènes caractéristiques des cellules endotheliales: CD31, VE -cadhérine, VEGFR1, VEGFR2, vWF, CXCR4, Tie-2. Nous avons également montré que les cellules progénitrices endothéliales ont une grande capacité de prolifération et de migration en comparaison avec d'autres cellules souches fœtales. Ces cellules peuvent prendre LDL acétylé, et la lectine *Ulex europaeus*, réseau vasculaire peut être formé, qui montrent leur potentiel dans l'angiogenèse et dans la réparation vasculaire. Cela a été confirmé en utilisant des sections ventriculaires embryonnaires murines viable ou soumis à une ischémie, sur lesquelles on a montré que les cellules progénitrices endothéliales ont la capacité d'intégrer et de

former des réseaux vasculaires. Nos résultats indiquent que les cellules progénitrices endothéliales formant les structures vasculaires seulement sections viables ventriculaires embryonnaires murins, tandis que le ischémique seulement intégrer ces cellules, ce qui démontre une communication directe avec l'autre.

Les résultats ont montré que l'acétylation des histones peut inhiber la différenciation des cellules progénitrices endothéliales. Les inhibiteurs de désacétylation (VPA, TSA, BuA) gardent la chromatine acétylée dans un état correspondant à un décondensent de forme.

Le niveau des désacétylases des histones a été diminué de manière significative en présence de ces inhibiteurs et le niveau de l'histone H3 acétylée a été augmenté et ces changements ont été en corrélation avec l'expression de marqueurs de différenciation impliqués dans des cellules progénitrices endothéliales. Les données de la biologie moléculaire et de l'immunophénotypage des inhibiteurs de HDAC ont montré que l'abaissement de l'expression du vWF, VEGFR2, eNOS, CD117, CD133, CD144, CXCR4 et Tie-2, alors que l'expression de CD34 et de CD45 reste inchangée montrant que les désacétylases des histones sont impliquées dans la différenciation des cellules endothéliale. Expression VE -cadhérine a été inhibée de manière significative à la fois au niveau de l'ARNm et des protéines. Le mécanisme sous-jacent de l'expression de la VE-cadhérine changement peut s'expliquer par ses facteurs de transcription de type incapacité de HoxC6 pour interagir avec les histones acétylées dans le but d'activer le promoteur de la VE- cadhérine. L'expression des gènes de CXCR4, Tie-2 et VEGFR2 significativement diminué après le traitement avec TSA, le mécanisme mis en jeu est contrôlé par des facteurs de transcription Hox dont l'expression est modulée en présence de ces inhibiteurs. Nos résultats ont montré que, dans l'état acétylé expression de l'HoxD9 dans les cellules progénitrices endothéliales est augmentée à la fois au niveau dugène et de la protéine.

Le processus de néovascularisation est un processus complexe impliquant une série d'étapes interconnectées conduisant à la formation de nouveaux vaisseaux sanguins quand les lésions vasculaires se produisent dans les organes adultes. A la différence de l'angiogenèse, qui est la formation de nouveaux vaisseaux sanguins à partir de certains néovascularisation préexistant, celui ci a lieu par l'intermédiaire des cellules progénitrices endothéliales. Ils sont mobilisées à migrer, proliférer et se différencier au niveau du site cible, sous l'action de cytokines et le micro-environnement. Nos résultats ont montré que l'acétylation inhibe la néovascularisation *in vitro*, agissant dans les processus de prolifération, l'adhésion, la migration et la différenciation

des cellules progénitrices endothéliales. Des cellules progénitrices endothéliales ont montré une diminution significative du niveau d'activité de la télomérase en comparaison avec le témoin, ce qui indique une diminution de la prolifération cellulaire. La motilité cellulaire évaluée en utilisant le " *wound healing-assay* " et par la mesure de l'impédance de la cellule, a montré que les inhibiteurs de HDAC diminuent la motilité cellulaire après 24 heures suivant la stimulation.

En revanche, la chimiotaxie des cellules progénitrices endothéliales ont augmenté après le traitement par les inhibiteurs de HDAC, ce qui peut s'expliquer par le maintien du phénotype de ces cellules progénitrices circulantes. En présence de 3 mM VPA on a montré une stimulation significative de la chimiotaxie des cellules progénitrices endothéliales par l'angiopoïétine, VEGF et SDF. Après la prolifération, la mobilisation, la migration des cellules endothéliales et l'adhésion au site cible, la dernière étape consiste à organiser leur réseau vasculaire. Nous avons poursuivi ce stage en termes d'acétylation. En poussant sur Matrigel en présence d' inhibiteurs de HDAC de cellules progénitrices endothéliales on a montré qu'ils ne peuvent pas former des réseaux vasculaires. Pour confirmer ces résultats, nous avons utilisé une autre matrice à base de collagène. Les résultats indiquent que les cellules progénitrices endothéliales isolées à partir de sang de cordon ombilical ont été capables de survivre et de se conformer à la matrice de collagène. De plus, ces cellules émettent des prolongements interagissent les uns avec les autres et avec la matrice, en formant la structure du réseau. En état acétylé, les cellules progénitrices endothéliales perdent cette capacité, ce qui démontre que l'acétylation inhibe la néovascularisation des cellules endothéliales *in vitro*.

Manipulation de l'activité de l'histone déacétylase pourrait être un outil utile pour générer des populations spécifiques de cellules pour la transplantation. Découvrir les modèles d'acétylation ("*acetylation signature*") impliqués dans la différenciation des cellules souches de différents types ouvre de nouvelles opportunités à l'interface entre la chimie et la biologie des cellules souches, et peuvent fournir des informations précieuses pour améliorer les applications des cellules souches dans l'ingénierie tissulaire et la médecine régénérative.

RESUME

Introduction - état actuel des connaissances

Les myopathies ischémiques et non ischémiques conduisent a dysfonction du ventricule gauche et, éventuellement, à l'insuffisance cardiaque. Ce dernier diminue la qualité de vie et la durée de vie augmente les coûts médicaux. Tout cela rend l'insuffisance cardiaque peut être l'un des problèmes principaux de santé dans le monde (McMurray et Pfeffer, 2005). Les thérapies actuelles fournissent dans un certain degré la survie et l'amélioration des symptômes, mai elles ne sont pas capable de renverser la condition du tissu cardiaque d'un état malade à un état sain (Kuraitis *et al.*, 2011). Le développement récent du domaine de recherche des cellules souches pourrait fournir un moyen de traiter l'insuffisance cardiaque en remplaçant les tissus endommagés au tissu sain, ce qui augmenterait la qualité de vie et la survie des patients atteints de différentes cardiomyopathies.

Les cellules-souches mésenchymateuses (MSC) de la moelle osseuse ont été intensivement étudiées pour leur capacité de régénération et propriétés immunomodulatrices. Des études sur des modèles animaux ont montré que la thérapie qui utilise MSC améliore la fonction cardiaque après un infarctus du myocarde en diminuant l'apoptose et en produisant de facteurs angiogéniques (Tang et *al.*, 2005). Vu que la capacité de différenciation de MSC en cardiomyocytes (CMC) est très basse et ne peut pas expliquer l'effet bénéfique transitoire observé pendant les études précliniques ou cliniques de transplantation au site d'infarctus (Rose et al., 2008), cet effet a été attribué aux facteurs avec action paracrine de ces cellules (Gnecchi *et al.*, 2008). Les MSC sont capables de libérer des facteurs solubles (cytokines, chimiokines, facteurs de croissance) qui agissent d'une manière paracrine sur les cellules lésées du myocarde. En plus, récemment il a été montré que les MSC sont capables de communiquer avec les cellules envoisinées par des fragments membranaires circulaires appelés microvézicules. Ainsi, MSC peuvent sécréter diverses composantes solubles, telles que : récepteurs, facteurs de croissance, lipides biologiquement actifs et acides nucléiques (ARNm et micro-ARN) protégés contre l'environnement extracellulaire agressif (Morel *et al.*, 2004, Gatti *et al*. 2011).

Les MSC présentent un certain nombre d'avantages pour la médecine régénérative, tels que: (i) ces cellules peuvent être facilement isolées et multipliées en culture pour obtenir un nombre approprié pour la thérapie cellulaire, (ii) elles ont une faible immunogénicité, ce que les rende aptes à la transplantation allogénique (Dai et al., 2005) et à cause de cela les questions éthiques

adjacentes à d'autres types de cellules-souches utilisées pour la transplantation, telles que les cellules souches embryonnaires, sont évitées (iii).

Dans ce contexte, l'objectif de cette thèse a été d'étudier certains aspects de l'apoptose de CMC en conditions ischémiques et la différenciation des MSC dérivées de la moelle osseuse de souris adultes en les cellules musculaires cardiaques. Ainsi, pendant toute la durée des études doctorales, les investigations ont été concentrés sur la compréhension des mécanismes par lesquels le muscle cardiaque est endommagé pendant et consécutive l'infarctus du myocarde et de trouver une méthode efficace pour sa réparation. Cette thèse est divisée en deux grandes parties: la première partie présente l'état actuel des connaissances sur le sujet de la thèse, présentée en quatre chapitres, pendant que la deuxième partie présente les contributions originales du doctorant à la connaissance scientifique internationale, qui ont été également organisées en quatre chapitres.

I. Altérations moléculaires conduisant à l'apoptose des cardiomyocytes pendant l'ischémie-reperfusion

À travers du premier chapitre on a essayé de répondre à la question : si l'ischémie ou la reperfusion soit responsable pour l'induction de l'apoptose dans les CMC. La connaissance du stimulus principal responsable de l'induction de l'apoptose dans les CMC est nécessaire afin de trouver un traitement pour ralentir la progression de l'insuffisance cardiaque due à la perte du myocarde contractile. Ainsi, l'objectif de cette première étude a été de déterminer la contribution individuelle de l'ischémie, de la reperfusion et des oxydants exogènes a l'induction de l'apoptose dans la CMC, en établissant la contribution majeure à la progression de l'insuffisance cardiaque dans La première partie des contributions originales a été axée sur l'identification du stimulus principal responsable de l'initialisation de l'apoptose dans le myocarde. Cette information est cruciale pour le développement de thérapies pour la progression de l'insuffisance cardiaque due à la perte de contractilité du myocarde. Les résultats obtenus dans cette première phase du stage de doctorat ont indiqué que le principal inducteur de l'apoptose dans l'ischémie / reperfusion a été la reperfusion plutôt que l'ischémie *per se*. L'étude a montré que les oxydants exogènes apportés de l'environnement lors de la reperfusion sont les principaux déterminants de l'apoptose des CMC. 25-hydroxycholestérol, une composante du LDL oxydé, favorise l'apoptose des CMC par un mécanisme dépendant de la caspase-3, ce qui implique l'augmentation de l'expression de la protéine pro-apoptotique Bax (Figure 1), régulée au niveau transcriptionnel, en même temps que

la dégradation post-traductionnelle de la protéine -anti-apoptotique Bcl-2 (figure 2). L'altération de la balance des protéines pro- et anti-apoptotiques a créé des conditions favorables pour lancer le processus d'apoptose, ce qui peut avoir lieu seulement pendant la reperfusion, quand les réserves d'ATP et de glucose sont restaurées. Les résultats de cette étude indiquent que la thérapie antioxydante pourrait jouer un rôle important pour sauver le myocarde viable après un infarctus en empêchant la perte de CMC par mort cellulaire programmée.

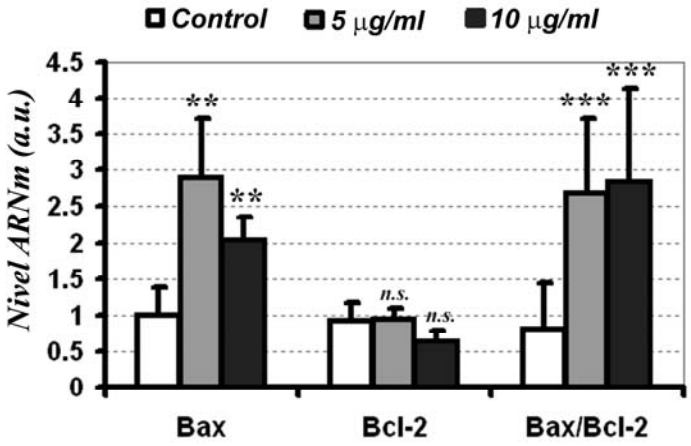

Figure 1: Les changements induits dans l'expression génique des protéines pro- et anti-apoptotiques Bax et Bcl-2 dans les CMC, après 72 heures de traitement avec 25-hydrohycholesterole.

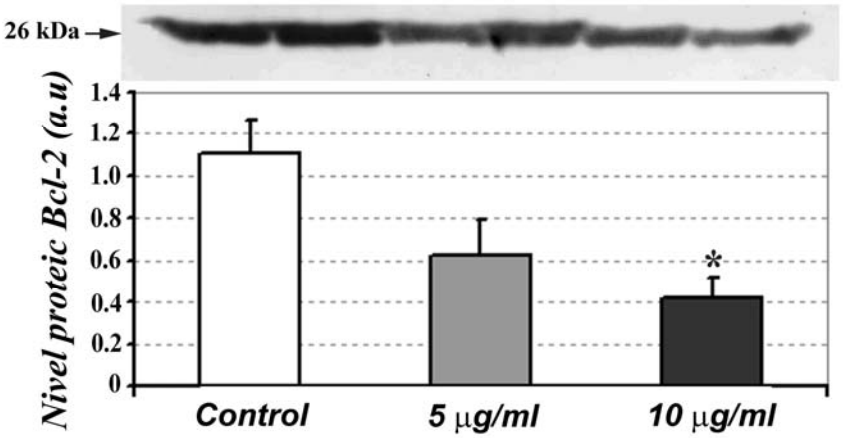

Figure 2: Quantification par Western blot des niveaux d'expression des protéines de la famille Bcl-2 après traitement par 25-hydrohycholesterol.

II. Isolement des cellules souches mésenchymateuses

L'étape suivante a consisté au développement des méthodes d'obtenir des MSC de la moelle osseuse de souris adultes, devant servir à utiliser dans des études de différenciation vers CMC. Cette phase des études doctorales a présenté un intérêt particulier parce que les MSC provenant de la souris sont plus difficiles à isoler et à propager *in vitro* que les cellules humaines ou de rat, à couse de la contamination avec des cellules hématopoïétiques. Pour cette raison, obtenir un MSC cultures à partir de la moelle osseuse de la souris était un défi qui a abouti à l'isolement de ces cellules simultanément par deux méthodes. La culture pure des MSC obtenue a ensuite été caractérisée comme suggéré par la Société internationale de Transplantation Cellulaire.

II.1. L'isolement des cellules souches mésenchymateuses par centrifugation sur gradient de Percoll

Les résultats obtenus ont montré que la centrifugation de la suspension cellulaire provenant de la moelle osseuse sur un gradient discontinu de Percoll entraîne la séparation des cellules en six fractions correspondant aux densités 1,050 1,057, 1,067, 1,070, 1,076, 1,083 et g / ml (figure 3).

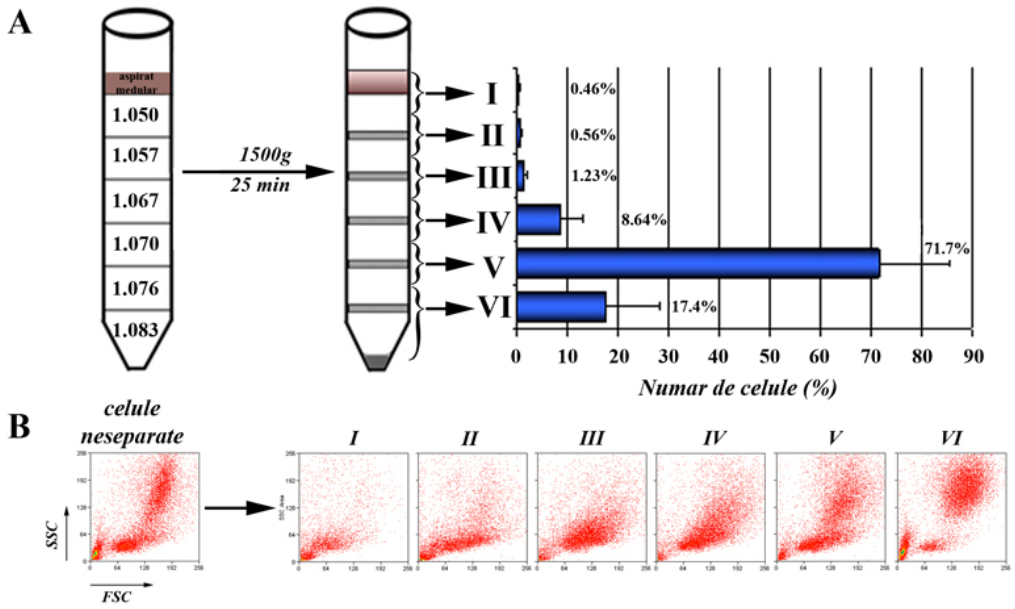

Figure 3: La séparation des cellules de la moelle osseuse en six fractions par centrifugation sur un gradient discontinu de Percoll. (A) Représentation schématique du gradient discontinu de Percoll utilisé pour le fractionnement des cellules et pourcentages correspondants à chaque fraction récupérée après centrifugation. (B) Histogramme de cytométrie de flux

montrant l'hétérogénéité des cellules avant la séparation et la morphologie des cellules dans chaque fraction.

Les cellules progénitrices, caractérisées par l'expression de marqueurs Sca-1 et c-kit ont été trouvés dans les fractions III-V. La fraction IVe a était considérée comme d'intérêt grâce à son contenu d'environ $2x10^6$ cellules souches à partir d'un total de $4.3x10^6$ cellules (figure 4).

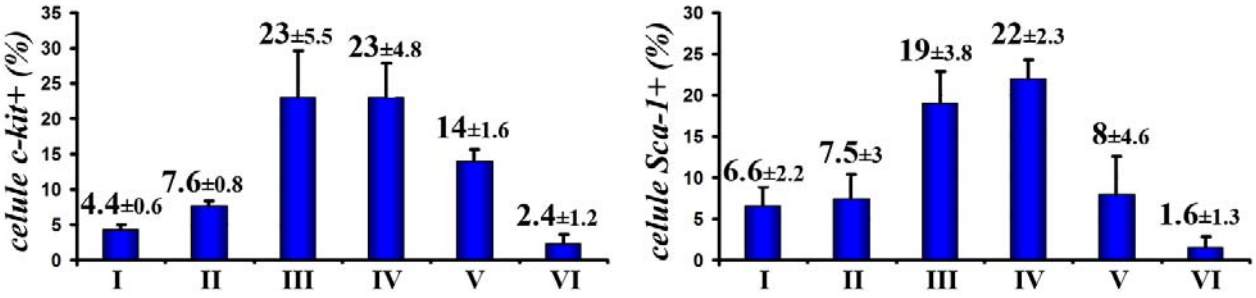

Figure 4: Représentation graphique de la moyenne des pourcentages des cellules c-kit$^+$ et Sca-1$^+$ correspondant a chaque fraction cellulaire, calculée à partir des résultats de trois expérimente différentes.

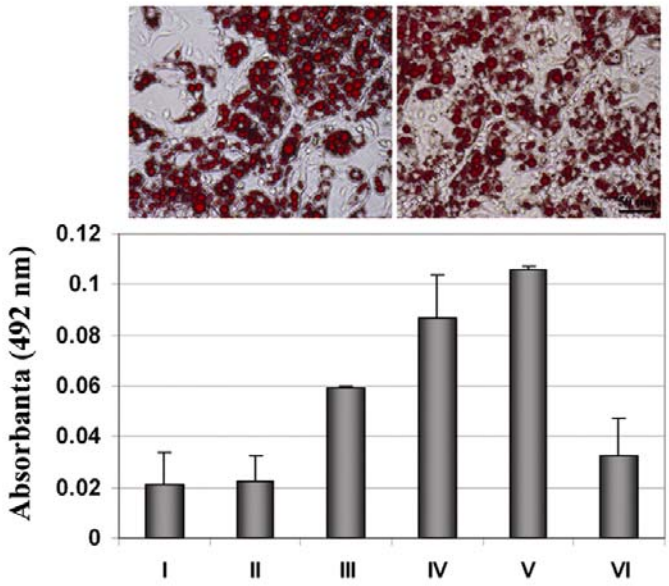

Figure 5: Quantification spectrophotométrique de l'accumulation de lipides dans les six fractions après cultiver les cellules dans un milieu de différenciation adipogénique. En haut se trouvent des images représentatives de fractions III et IV colorées avec Oil Red. La V fraction, bien qu'elle présente une accumulation massive de lipides, n'est pas enrichie de cellules souches, la coloration étant probablement due à la présence des pré-adipocytes à ce niveau.

Bien que la composition cellulaire de cette fraction ait été hétérogène, elle a compris, outre des cellules c-kit et Sca-1 positive, aussi des cellules endothéliales, qui pourraient jouer un rôle important dans le rétablissement du myocarde endommagé après un infarctus, en contribuant à la revascularisation du tissu par l'angiogenèse. En culture, cette fraction a généré des cellules $CD45^-$ /$c\text{-}kit^-$/$Sca\text{-}1^+$ / $PECAM^-$/$VEGFR2^-$/$osteocalcine^-$/colagen II, qui ont généré des adipocytes et des ostéoblastes par incubation dans milieux de différenciation spécifique, en montrant la nature multipotente de ces cellules (figures 5 et 6).

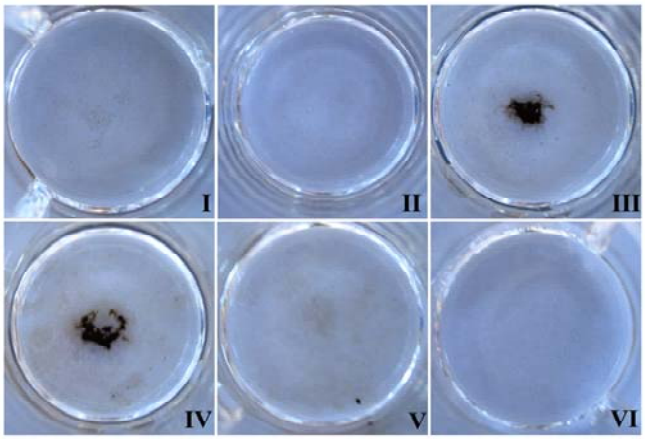

Figure 6: Image en microscopie optique représentant la coloration von Kossa des cellules adhérentes correspondant aux six fractions après deux semaines de culture en milieu de différenciation ostéogénique. On peut observer que les fractions III et IV, mais pas fraction V (qui contienne la majorité des cellules) ont été en mesure de générer des ostéoblastes dans des conditions de culture spécifiques.

II.2. L'isolement de cellules souches mésenchymateuses de la moelle osseuse hématogène

En parallèle avec la méthode présentée ci-dessus, on a ainsi obtenu une population de cellules souches mésenchymateuses à partir de la de moelle osseuse hématogène par maintenir les cellules adhérentes en culture pendant une période plus longue, d'environ huit semaines. Les cellules dérivées ont formé une culture homogène qui présentait une apparence fibroblast-like et un fort potentiel de prolifération. La caractérisation de cette culture par RT-PCR (figure 7a) a

montré une expression de marqueurs de cellules souches Sca-1 et CD105 (endogline), et l'absence de marqueur c-kit, qui a indiqué une déplétion des cellules souches hématopoïétiques. Une autre caractéristique de ces cellules a été la présence de filaments intermédiaires de vimentine et de nestine. L'expression de ces protéines (figure 7b) a suggéré un rôle possible dans la régénération des tissus vue que la présence de filaments de nestine soit spécifique des cellules jeunes ayant une capacité migratoire.

La caractérisation de ces cellules a été complétée par des études de différenciation en plusieurs types de cellules, comme les adipocytes, ostéoblastes et les chondrocytes. Cela a montré leur caractère multipotent qui a été maintenu inchangé pendant plusieurs passages (figure 8). Cette culture a été utilisée dans des études ultérieures qui ont suivi la différenciation dans un phénotype musculaire, dont les résultats sont présentés au chapitre III de cette thèse.

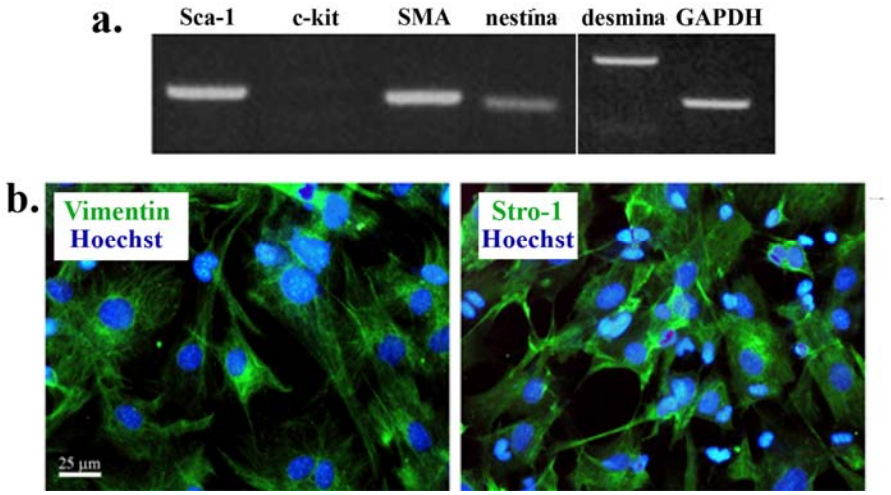

Figure 7: (a) RT-PCR montrant le niveau d'expression de l' ARNm de marqueurs de MSC: Sca-1, l'actine spécifique pour les cellules musculaires lisses (SMA) et la desmine. On peut observer aussi l'absence de l'expression du marqueur de cellules souches hématopoïétiques c-kit (b) Image d' immunocytochimie qui montre la présence des filaments intermédiaires de vimentine et l'expression du marqueur des cellules stromales Stro-1 dans toutes les cellules en culture.

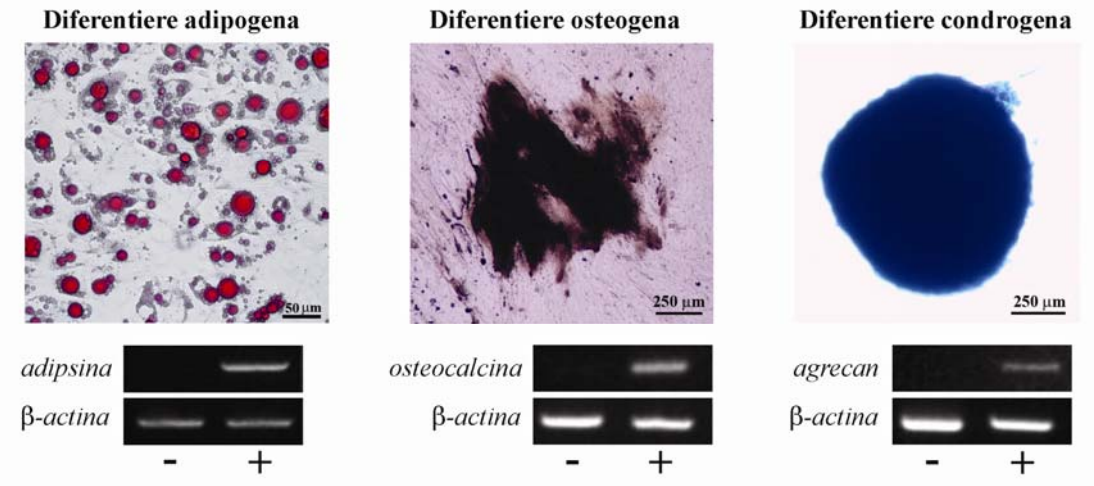

Figure 8: Caractérisation du caractère multipotent des MSC. Sur le côté gauche de l'image on peut observer la différenciation des cellules en adipocytes, mise en évidence par coloration des accumulations de lipides intracytoplasmiques avec Oil Red O et la détermination de l'expression génique de l'adipsine par RT-PCR. Au centre de l'image la différenciation de cellules dans ostéoblastes est présentée. En haut il se voit la coloration von Kossa et ci-dessous l'expression d'ostéocalcine (RT-PCR) est illustré. Sur la droite la coloration au Bleu Alcian des mucopolysaccharides acides cellules spécifiques pour les chondrocytes différenciés et l'expression génique du protéoglycane agrecan dans sont présentés.

III. La différenciation des cellules souches mésenchymateuses en cardiomyocytes

Pour induire la différenciation MSC vers un phénotype cardiaque 5-azacytidine, un composé agissant déméthylation du matériel génétique, connu pour sa capacité à améliorer la différenciation des cellules souches embryonnaires à CMC, a été utilisé.

L'action de la 5-azacytidine sur la propriété des cellules souches de se différencier en lignées cellulaires multiples a été un point d'intérêt de cette thèse. Les résultats ont montré que les cellules traitées avec 5-azacytidine et ont progressivement perdu leur capacité à se différencier en adipocytes et ostéoblastes quand ils ont été incubés dans des conditions de différenciation spécifiques. L'augmentation du potentiel de différenciation des MSC dans chondrocytes après traitement avec 5-azacytidine a été un résultat inattendu. La conclusion de cette étude a été : les MSC conservent leur propriété de différenciation après la première exposition à l'action de la 5-azacytidine, mais elle est progressivement réduite à chaque exposition, en augmentant la capacité de générer des chondrocytes (figure 9).

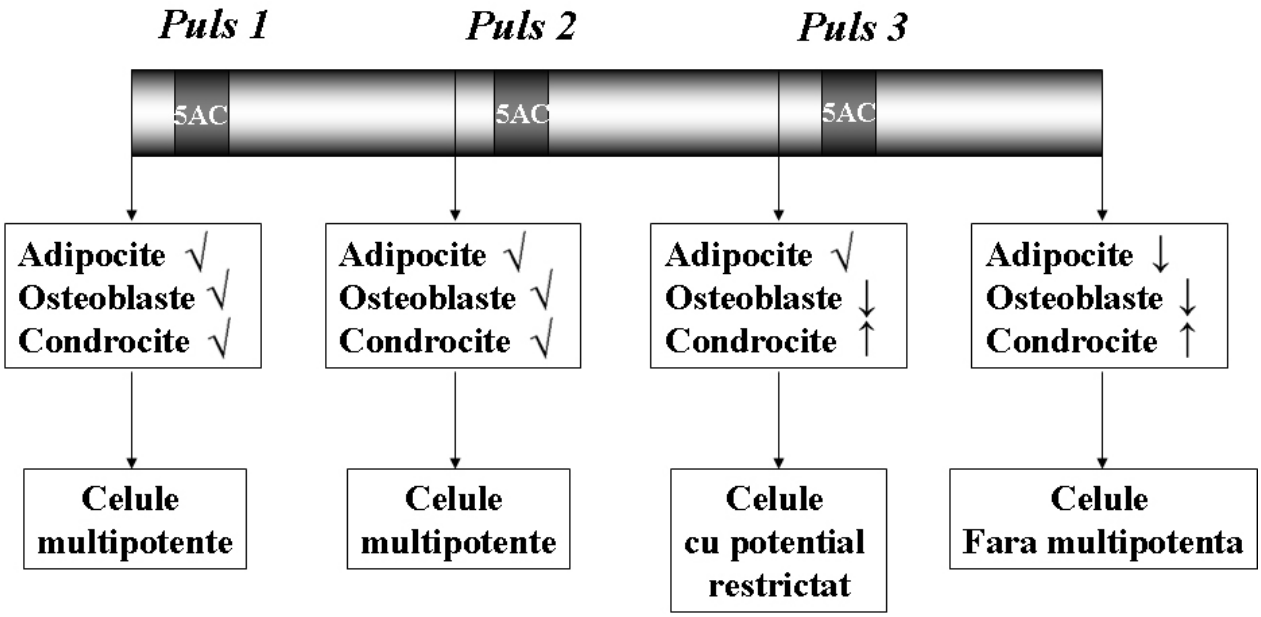

Figure 9: L'effet du traitement avec 5-azacytidine sur la capacité des MSC de différenciation en lignes cellulaires multiples. Cette propriété est devenue plus restrictive après exposition au 5-azacitidine. Après 2 ou 3 traitements avec 5-azacitidine, la capacité de se différencier en chondrocytes a été augmenté de manière significative.

Avec soulignant les modifications du caractère pluripotent des MSC par traitement avec la 5-azacytidine, on a poursuivi la capacité de cet agent chimique à induire la différenciation de ces cellules vers un phénotype musculaire cardiaque. Les figures 10 et 11 montrent que, sauf pour quelques gènes musculaires spécifiques (α-actine cardiaque, canal de calcium du type L), l'expression d'aucune des gènes impliqués dans la différenciation des cellules musculaires cardiaques n'a pas été induite dans les cellules traitées. Cependant, 5-azacytidine a induit l'expression des gènes spécifiques du muscle squelettique, ce qui a permis la différenciation des MSC en myoblasts quand incubées en conditions myogènes spécifiques (figure 12). En conclusion, le traitement avec 5-azacitidine pourrait favoriser la différenciation des MSC en cellules cardiaques, à condition de déterminer les facteurs spécifiques qui pourraient affecter la réalisation de la différenciation en CMC matures et fonctionnelles.

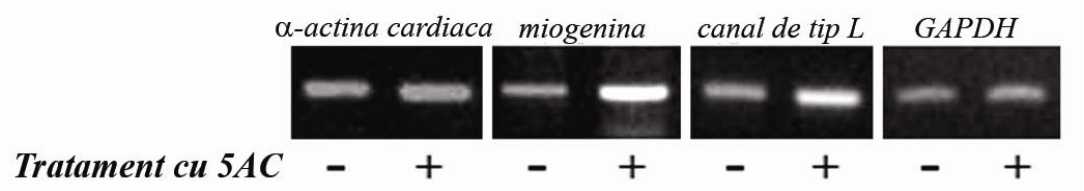

Figure 10: RT-PCR montrant l'expression augmentée des gènes musculaires spécifiques après le traitement avec 5-azacitidine.

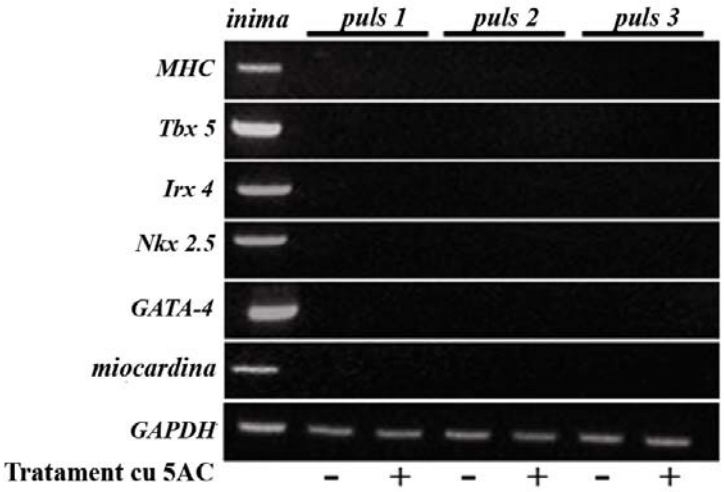

Figure 11: RT-PCR qui montre l'absence de l'expression des facteurs de transcription et d'autres gènes spécifiques du myocarde après le traitement avec 5-azacitidine.

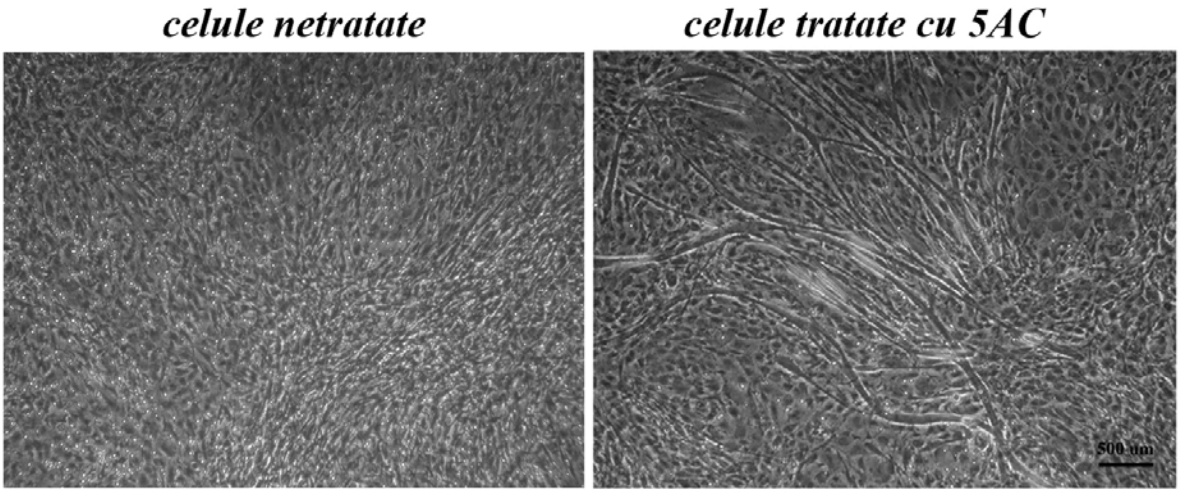

Figure 12: Image de microscopie à contraste de phase qui montre les myotubes formés dans les cultures de MSC traités par 5-azacytidine après privation de sérum.

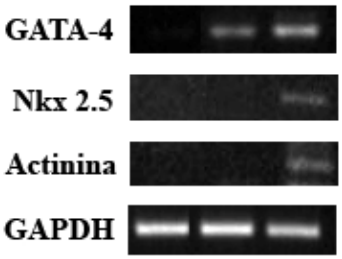
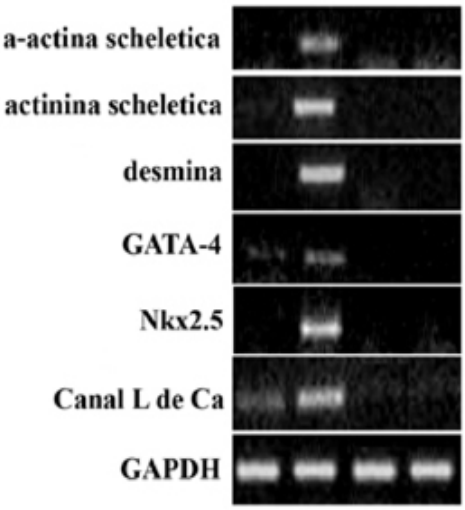
Suite à ces observations, nous avons constaté que le traitement avec 5-azacitidine associée à un contact direct avec les cellules du myocarde peut avoir un effet bénéfique sur la différenciation des cellules stromales en CMC. Ainsi, nous avons suivi les changements dans les cellules stromales de la moelle par contact direct avec les cellules musculaires cardiaques. Les résultats montrent qu'en effet, la cummulation des deux facteurs induisant la differentiation conduit à l'initiation de l'expression des facteurs de transcription cardiaques spécifiques, tels GATA-4 et Nkx2.5 (figure 13), dans les cellules stromales de la moelle osseuse de souris. En plus, l'expression de l-actinine, un indicateur de la différenciation vers un phénotype de muscle strié a été observée.

De plus, les résultats des experiments de coculture dans chambre double, un système qui permet le passage des molécules par les pores d'une membrane semipermeable, ont montré que les facteurs solubles libérés par le myocarde ischémique cumulent avec le traitement avec 5-azacitidine conduit l'augmentation du processus de différenciation des cellules de la moelle osseuse vers un phénotype cardiaque. Ainsi, l'accumulation de l'exposition au 5-azacytidine et de l'action des signaux provenant du myocarde ischémique entraînent l'initiation de la transcription des principaux facteurs impliqués dans la différenciation des cellules musculaires cardiaques tels que: l'actine musculaire, l'actinine, desmine, GATA-4, Nkx2.5 et des canaux de calcium de type L (figure 14). Ainsi, on peut conclure que l'initiation de la différentiation induite par la déméthylation de certains gènes est aidée par l'effet de facteurs solubles cardiaques qui sont en mesure d'achever ce processus.



CSA	+	+	+
CMC	-	+	+
5AC	-	-	+

Figure 13: RT-PCR montrant l'induction de l'expression génique des marqueurs cardiaques dans les cellules traitées avec 5-azacitidine après 1 semaine en culture avec CMC fœtales. On peut observer que l'effet cumulatif de ces deux conditions (traitement avec 5-azacitidine et contact direct entre les cellules stromales et CMC) est supérieur au simple contact entre les deux types cellulaires.



Inima	+	+	-	-
CSA	+	+	+	+

Figure 14: RT-PCR montrant l'induction de l'expression génique des marqueurs des cellules musculaires cardiaques dû à l'effet cumulatif des facteurs induisant la différenciation des cellules stromales de la moelle osseuse dans CMC: 5-azacytidine et facteurs secrétés par le myocarde ischémique.

IV. Mise en évidence des facteurs paracrins sécrétés par les cellules souches mésenchymateuses en conditions normales et hypoxique

Le dernier chapitre de cette thèse a été réalisé dû aux rapports récents de la littérature sur les résultats d'essais cliniques. Ils ont montré que les effets bénéfiques de la greffe de cellules souches dans l'infarctus du myocarde sont transitoires, ce qui suggère un effet paracrin exercé par les cellules transplantées par l'intermède des facteurs angiogéniques et cardioprotecteurs secretés. Ainsi, la dernière partie de cette thèse comprit l'étude de l'effet anti-apoptotique de facteurs solubles libérés par MSC sur les cellules musculaires cardiaque et l'identification des facteurs cardioprotecteurs secretés par les MSC en conditions normales et hypoxiques. Une observation particulièrement importante observée à partir de ces expériences a été la capacité des MSC de s'adapter et survivre en conditions hypoxiques, montrée par la résistance de ces cellules à l'apoptose induite par la hypoxie (Figure 15).

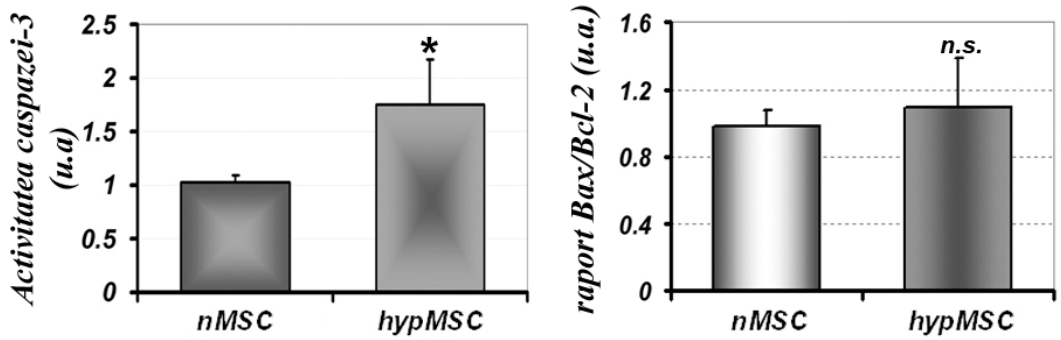

Figure 15: Illustration de la résistance des MSC en conditions ischémiques: le graphique de gauche montre une légère augmentation de l'activité de la caspase-3, tandis que le ratio de l'expression du gène pro-apoptotique Bax et du gène anti-apoptotique Bcl-2, tel que déterminé par PCR quantitative, reste inchangé (graphique de droite).

La résistance des MSC à l'hypoxie induite par apoptose est particulièrement importante pour leur survie dans le myocarde ischémique, où le milieu est dépourvu d'une vascularisation adéquate pour assurer le nécessaire d'oxygène.

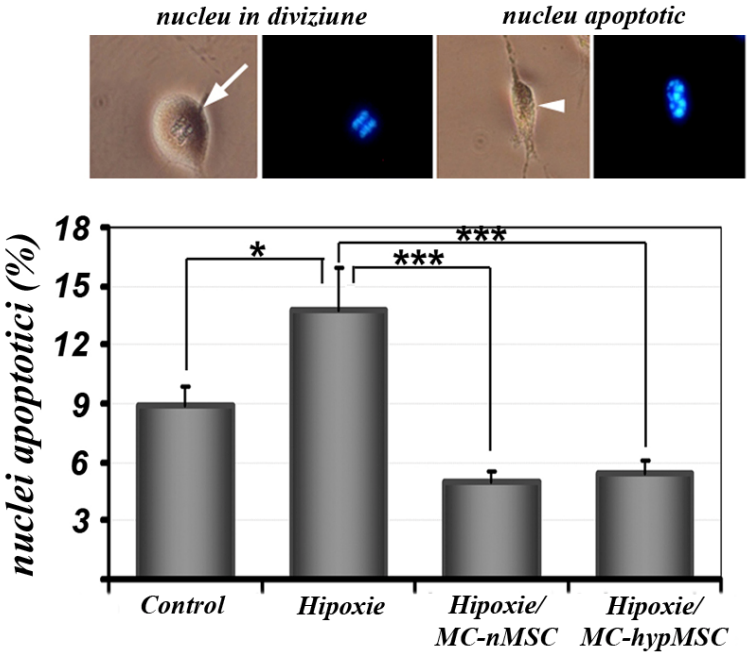

Figure 16: Détermination quantitative de l'apoptose dans les myocytes cardiaques après exposition à l'hypoxie en présence et en absence du milieu conditionné. Le tableau en bas présente les pourcentages des noyaux apoptotiques déterminées par coloration au Hoechst. Au moins 1000 noyaux ont été comptés pour chaque test (, p <0,05, *** p <0,001). On peut observer en haut de cette image des exemples des noyaux apoptotiques, aussi que des noyaux en division.*

L'étude de l'effet du milieu conditionné des MSC sur les CMC incubées en conditions hypoxiques a montré que ces cellules sont capables de secréter des facteurs avec action cardioprotectrice. La supplémentation du milieu des CMC incubées en conditions hypoxiques avec milieu conditioné des MSC a empêché l'induction de l'apoptose (Figure 16). Les résultats ont montré le maintien de l'intégrité de la membrane mitochondriale, ce qui a permis d'éviter l'initiation apoptose. En plus, le milieu des MSC hypoxique a eu des effets similaires à cela récolté à partir des cellules cultivées en atmosphere normoxique (20% O_2), ce qui montre que les MSC conservent leurs propriétés cardioprotectrices pendant l'incubation en conditions hypoxiques. Ce résultat suggère que les MSC transplantées dans le myocarde hypoxique sont capables de contribuer à la survie des CMC affectées par le stress oxydatif et l'hypoxie durant la reperfusion.

L'étude de la composition du milieu conditionné des a montré que ces cellules sont capables de conserver la capacité de synthétiser et libérer certains facteurs cardioprotecteurs tels que certaines cytokines et microARN. Ainsi, on a identifié quelques cytokines sécrétées par le MSC incubés dans des conditions normales, dont quatre ont été trouvés en quantités similaires dans le MSC incubées en hypoxie: TIMP-1, MCP-1, SDF-1α et IL1ra (Figure 17).

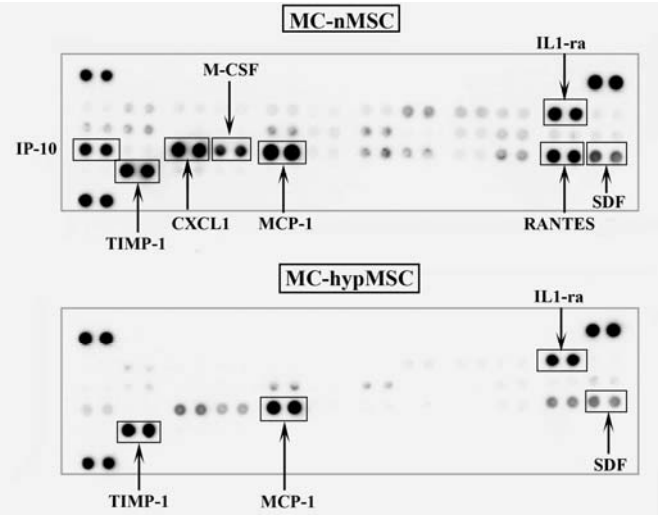

Figure 17: Identification des cytokines sécrétées par MSC en conditions normoxiques (image du haut) et hypoxiques (en bas) par la technique " cytokine array ".

Conformément à la littérature, ces facteurs pourraient être responsables, au moins partiellement, de l'effet cardioprotecteur exercé par la présence des MSC dans le myocarde ischémique, soit grâce à l'action anti-apoptotique ou à a la capacité d'induire le processus d'angiogenèse, important pour rétablir l'approvisionnement du tissus d'oxygène et de nutriments.

Outre ces molécules, il semble que le transfert d'information génétique entre MSC et cellules endommagées est un mécanisme important, qui pourrait être responsable de l'effet réparateur des MSC. Ainsi, on a observé dans le milieu extracellulaire des MSC hypoxiques une augmentation de la quantité des microARN 199a et 1225b, connus pour leur effet anti-apoptotique (Figures 18 et 19).

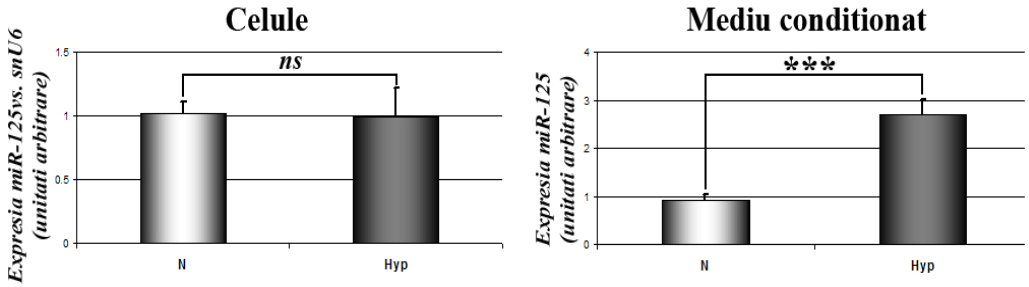

*Figure 18: Quantification du microARN-125 par PCR quantitative dans les MSC incubés en conditions de normoxie et d'hypoxie (graphique de gauche) et le milieu extracellulaire récoltées à partir de cellules maintenues dans les deux conditions (*** p <0,0005).*

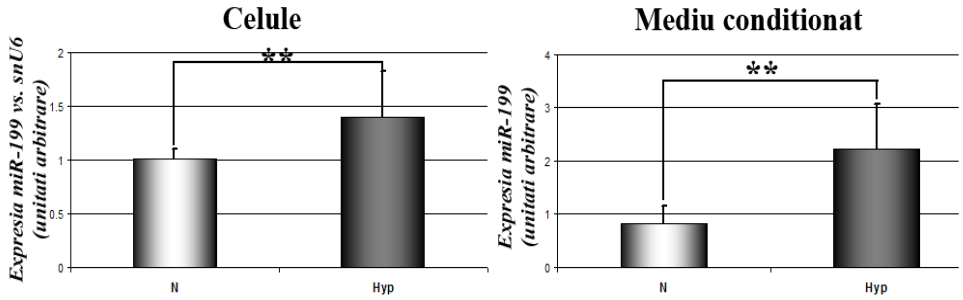

*Figure 19: Quantification du microARN-199 par PCR quantitative dans les MSC incubés en conditions de normoxie et d'hypoxie (graphique de gauche) et le milieu extracellulaire récoltées à partir de cellules maintenues dans les deux conditions (** p<0.005).*

En conclusion, la composition du milieu extracellulaire des MSC consiste en une combinaison de facteurs avec effet soit anti-apoptotiques (TIMP-1, MCP-1, miR-199a, miR-125b), soit inhibiteurs de croissance des fibroblastes (IL1ra) ou angiogéniques (SDF-1α). La présence de ces facteurs cardioprotecteurs dans sécrétion des MSC pourrait être responsable de l'effet anti-apoptotique sur les CMC incubées en conditions hypoxiques observé dans nos expériences.

Conclusions

L'information contenue dans cette thèse a été matérialisée dans des articles publiés en revues internationales à facteur d'impact ISI, des présentations orales ou des affiches aux réunions scientifiques nationales et internationales. Au cours de la préparation de la thèse, les résultats suivants ont été obtenus:

- On a montré que le facteur principal responsable pour l'initialisation de l'apoptose des CMC soumis à l'ischémie est représenté par les oxydants exogenes amenés par la réperfusion au site de la lesion;
- On a établi une méthode pour purifier une population de cellules progénitrices par fractionnement de la moelle osseuse par centrifugation sur gradient discontinu de Percoll ;
- On a obtenu des cultures homogène de MSC, caractérisées conformément aux normes fixées par la Société Internationale de tTransplantation Cellulaire ;
- L'effet de l'action de déméthylation de 5-azacytidine sur la nature pluripotente des MSC a été montré;
- On a démontré l'effet accru de la cumulation de 5-azacytidine et des facteurs secrétés par le myocarde pour l'augmentation de la différenciation des MSC vers un phénotype cardiaque;
- On a démontré l'effet anti-apoptotique des facteurs libérés par MSC normale et hypoxique sur CMC;
- Des facteurs avec action anti-apoptotique, anti-fibrotique et pro-angiogénique ont été identifiés dans le milieu extracellulaire des MSC incubées en conditions normales et hypoxique ; ces facteurs pourraient être responsables de l'action cardioprotectrice de ces cellules.

Introducere şi obiective

Bolile cardiovasculare reprezintă principala cauză de mortalitate în ţările dezvoltate, inclusiv în România (60%). Ateroscleroza este o boală complexă, multifactorială şi multigenică caracterizată prin îngroşarea şi rigidizarea pereţilor arteriali - determinând îngustarea progresivă a lumenului vascular. Acesta reprezintă un factor determinant al bolilor coronariene şi cerebrovasculare. Ateroscleroza afectează primar: a) arterele elastice (aorta, carotida, iliaca); b) arterele musculare medii şi mari (coronare, cerebrale, poplitee). Cei mai întâlniți factori de risc ai aterosclerozei sunt neinfluenţabili: vârsta avansată, sexul, predispoziţia genetică şi influenţabili: dislipidemii, creşterea LDL (lipoproteine de densitate scăzută), reducerea HDL (lipoproteine de densitate crescută), fumatul, hipertensiunea arterială, diabetul zaharat, obezitatea, sedentarismul, factori psihosociali (Libby, 2002). Deşi toată suprafaţa vaselor de sânge este expusă la factorii de risc, leziunile aterosclerotice apar cu precadere în anumite zone particulare ale arborelui vascular: peretele interior al bifurcaţiilor vasculare, curburile arteriale şi valvele aortice (Simionescu et al, 1986).

Terapia primară a aterosclerozei include medicamente care scad biosinteza endogenă a colesterolului, de exemplu inhibitori ai 3-hidroxi-3metilglutaril-Coenzima A reductaza (statine). Insă aproximativ 50% dintre pacienţi dezvoltă leziuni aterosclerotice în absenţa hipercolesterolemiei. Folosirea statinelor previne complicaţiile bolilor coronariene acute prin stabilizarea plăcii aterosclerotic, nu prin reducerea dimensiunilor acesteia (Aikawa şi Libby, 2004). Până în prezent abordările terapeutice sunt limitate la factori de risc, ţintind cu predilecţie hipercolesterolemia şi hipertensiunea, însă eficacitatea maximă a acestor strategii în studiile clinice a fost de 30-40% (Soto et al, 2012). Prin urmare există o nevoie de a proiecta terapii specifice care să vizeze mecanismele patologice de formare şi dezvoltare a ateroamelor.

În procesul formării plăcilor aterosclerotice un rol important îl au macrofagele (Mac). Acestea sunt derivate din monocite şi sunt celule versatile care îşi modifică fenotipul ca răspuns la factorii existenţi în micromediul plăcii. Mac provin din măduva osoasă hematogenă şi trec prin diferite stadii, de la celula stem pluripotentă-monoblast-promonocit-monocit circulant. Disfuncţia endoteliului cauzată de particulele de LDL transcitate şi acumulate în subendoteliu determină expresia crescuta de MCP-1 ceea ce va conduce la diapedeza monocitelor prin joncţiunile celulelor endoteliale. Acestea se vor diferenţia în Mac activate, vor acumula lipide şi se vor transforma în celule spumoase. Răspunsul inflamator crescut va fi menţinut prin secreţia de molecule pro-inflamatorii şi prin producerea de specii reactive de oxigen (SRO). De asemenea, Mac apoptotice sunt responsabile de formarea centrului necrotic şi de progresia bolii. Datorită rolului important pe care macrofagele îl au în diferitele etape de formare a plăcii aterosclerotice acestea reprezintă ţinte atractive pentru dezvoltarea de terapii.

Studiile recente indică rolul determinant al mecanismelor epigenetice în modularea fenotipului Mac în ateroscleroză. Enzimele histon acetil transferaze (HAT) catalizează acetilarea resturilor de lizină din regiunea amino-terminală a histonelor nucleozomale. În urma acestui proces are loc decondensarea cromatinei, care facilitează accesul factorilor de transcriere la elementele lor de consens din secvenţa ADN şi implicit activarea expresiei genice. Acetilarea histonelor este asociată cu hipertrofia miocitelor, apoptoză, stres oxidativ, remodelare cardiacă, aritmie, insuficienţă cardiacă, hipertensiune şi inflamaţie (referinta).

Scopul acestei teze de doctorat îl constituie identificarea de noi mecanisme moleculare de natură epigenetică în macrofage, în vederea dezvoltării unor noi abordări terapeutice anti-inflamatorii şi anti-oxidante în ateroscleroză.

Ipoteza care a determinat acest studiu o reprezintă faptul că dezechilibrul mecanismelor epigenetice implicate în acetilarea histonelor determină alterarea exprimării unor gene cu rol important în modularea funcţiei macrofagelor pro-inflamatorii (tip M1) şi respectiv anti-inflamatorii (tip M2) în ateroscleroză.

În prima parte a tezei vor fi discutate aspecte actuale referitoare la procesul inflamator asociat aterosclerozei, implicarea inflamaţiei şi a Mac în toate stadiile de dezvoltare a ateroamelor şi a mecanismelor epigenetice, în mod special în ceea ce priveşte acetilarea şi dezacetilarea, mecanisme ce intervin în procesul de formare a plăcilor aterosclerotice.

Partea originală a tezei se refera la : (1) Analiza impactului condiţiilor aterogene asupra sistemului acetilării/dezacetilării histonelor: HAT şi HDAC; (2) Investigarea implicării HAT şi HDAC în instalarea stresului oxidativ şi inflamator la nivelul macrofagelor polarizate în ateroscleroză; (3) Determinarea potenţialului unor compuşi farmacologici direcționaţi către HAT/HDAC în scopul de a reduce formarea plăcilor aterosclerotice la şoarecii ApoE -/-.

Numeroase studii arată că în afară de factorii genetici, mecanismele epigenetice care traduc efectele interacţiilor gene-(micro)mediu contribuie la ateroscleroză prin reglarea exprimării unor gene foarte importante asociate cu inflamaţia, sinteza de matrice extracelulară, proliferarea celulelor şi diferenţiere (Khyzha et al, 2017; Zhang et al, 2018). Stresul oxidativ este un reglator important al numeroaselor procese patologice care duc la formarea plăcilor de aterom. Cu toate acestea, implicarea mecanismelor epigenetice în medierea supraexprimării de SRO şi stres oxidativ în ateroscleroză nu este încă definită (Kietzmann et al, 2017). În acest studiu ne-am concentrat atenţia asupra mecanismelor dependente de HAT implicate în modularea exprimării Nox5, un membru al familiei Nox identificat şi caracterizat în Mon şi Mac umane care contribuie la supraexprimarea SRO şi a stresului oxidativ în ateroscleroză (Manea et al, 2015).

Studii recente indică rolul SRO produse de Nox5 în etiologia bolilor cardiovasculare (BCV), însă mecanismele precise care guvernează inducerea Nox5 nu sunt pe deplin cunoscute (Jha et al, 2017). De aceea, înţelegerea căilor moleculare ale reglării genei Nox5 reprezintă un pas necesar pentru dezvoltarea de terapii avansate anti-stres oxidativ care să reducă semnificativ evenimentele cardiovasculare asociate cu destabilizarea plăcii aterosclerotice vulnerabile (ex. accident cerebral vascular, infarct miocardic, moarte subită). Astfel, a fost emisă ipoteza că nivelul crescut al Nox5 poate fi mediat parţial de modificările topologiei cromatinei. Pentru a aborda această problemă a fost realizat un design experimental folosind probe umane non- şi aterosclerotice obţinute ca materiale reziduale de la pacienţi care au suferit operaţii de endarterectomie şi Mac umane în cultură.

Rezultatele originale obţinute în această teză demonstrează că:

1. Nivelele proteice corespunzătoare p300, HAT1, H3K27ac şi Nox5 sunt induse în arterele carotide aterosclerotice umane şi sunt abundente în zona capului fibros şi a miezului lipidic aterosclerotic care exprimă markerii pan-Mac.

2. Stimularea Mac umane cu LPS induce modificări epigenetice observate prin creşterea nivelului HAT1 şi a acetilării histonelor (H3K27ac, H3K9ac).

3. Inhibarea farmacologică a HAT reduce exprimarea genică şi proteică în Mac stimulate cu LPS; supraexprimarea p300 sau HAT1 induce activarea transcrierii genei Nox5.

4. Recrutarea proteinelor p300 şi HAT1 este crescută la nivelul promotorului genei Nox5 în Mac umane tratate cu LPS.

5. HDAC clasa I (HDAC1, HDAC2, HDAC3), clasa IIa (HDAC4), clasa IIb (HDAC6) şi HDAC IV (HDAC11) sunt crescute în arterele carotide aterosclerotice umane şi în aortele hipercolesterolemice ale şoarecilor ApoE-/.

6. Inhibarea farmacologică a HDAC de către SAHA reduce semnificativ dezvoltarea aterosclerozei şi a markerilor infiltrării celulelor imune în aortele şoarecilor ApoE-/-.

7. Căile de semnalizare dependente de HDAC mediază inducţia exprimării Nox1 şi Nox4 în aortele şoarecilor ApoE-/-.

8. Tratamentul cu SAHA induce scăderea proteinelor NOS2 şi MMP9 din aorta, contribuitori majori ai inflamaţiei vasculare şi remodelării în ateroscleroză.

9. Subtipurile HDAC clasa I, IIa, IIb şi IV precum şi izoformele Nox1, Nox2 şi Nox4 sunt semnificativ crescute în Mac de şoarece pro-inflamatorii M1 *in vitro*.

10. Inhibarea farmacologică a HDAC (de către SAHA) reduce exprimarea nivelelor Nox1, Nox2, Nox4 şi TNFα în Mac de şoarece M1 in cultură.

În ansamblu, datele acestei teze de doctorat întăresc convingerea că p300 are un rol important în medierea inducerii exprimării lui Nox5 în Mac, în condiţii inflamatorii şi furnizează noi date care creează o legătură între mecanismele modificate epigenetic şi supraproducţia de SRO cauzate de Nox5 în ateroscleroză. Ţinând cont de faptul că stresul oxidativ este un factor incriminat în ateroscleroză, ţintirea farmacologică a mecanismelor epigenetice ale căilor care controlează exprimarea Nox5 poate să fie o strategie terapeutică eficientă în tratarea acestei boli.

Interesant, rezultatele noastre furnizează dovezi că în contextul inducerii diferitelor izoforme HDAC, inhibitorul pan-HDAC SAHA prezintă efecte anti-aterosclerotice similare în

şoareci, comparabile cu studiile precedente care subliniau faptul că ablaţia sistemică sau specifică unei singure izoforme HDAC încetineşte ateroscleroza. De aceea, existenţa compensatorie sau a unor mecanisme reglatorii redundante în sistemul HDAC, precum şi a unei reţele complexe între subtipurile HDAC şi celule/factori de transcriere specifici genelor rămâne o problemă deschisă. În acest context, utilizarea inhibitorilor pan- sau a celor specifici HDAC în ateroscleroză este încă disputată şi necesită studii aprofundate. Colectiv, principalele descoperiri ale acestui studiu indică faptul că în ateroscleroză inhibarea farmacologică a creşterii HDAC reduce exprimarea crescută a subtipurilor Nox în aortă şi deasemenea şi a stresului oxidativ, duce la scăderea markerilor inflamatori şi a formării leziunilor aterosclerotice în şoareci. Deoarece multiplele subtipuri HDAC sunt deasemenea crescute în ateroscleroza umană, intervenţiile farmacologice orientate către HDAC ar putea fi o nouă strategie terapeutică eficientă în ateroscleroză.

Colectiv, principalele descoperiri ale acestui studiu indică faptul că în ateroscleroză inhibarea farmacologică a creşterii HDAC reduce exprimarea crescută a subtipurilor Nox în aortă şi de asemenea şi a stresului oxidativ, duce la scăderea markerilor inflamatori şi a formării leziunilor aterosclerotice în şoareci. Deoarece multiplele subtipuri HDAC sunt de asemenea crescute în ateroscleroza umană, intervenţiile farmacologice orientate către HDAC ar putea fi o nouă strategie terapeutică eficientă în ateroscleroză.

Granturi

1. PNCDI III, **P2 - Creșterea competitivității economiei românești prin CDI**
Tip proiect: Proiect experimental demonstrativ (PED), Contract nr. 342/2020
Titlul proiectului: Strategie teranostica avansata in ateroscleroza care integreaza interventii farmaco-epigenomice si microbule biomimetice pentru administrarea tintita a medicamentelor cu ajutorul ultrasunetelor
Perioada: August 2020 - Iulie 2022
Director de proiect: Dr. Adrian Manea

2. PNCDI III, P2 - Creșterea competitivității economiei românești prin CDI
Tip proiect: Proiect experimental demonstrativ (PED), Contract nr. 265/2020
Titlul proiectului: Strategie farmacologica inovatoare bazata pe triterpene pentru tratamentul complicatiilor micro- si macrovasculare asociate diabetului zaharat – studiu preclinic
Perioada: August 2020 - Iulie 2022
Director de proiect: Dr. Simona-Adriana Manea

3. PNCDI III, Programul 4 - Cercetare fundamentala si de frontiera
Tip proiect: Proiecte complexe de cercetare de frontiera, Contract nr. 5/2018
Titlul proiectului: Tintirea mecanismelor imunitatii innascute pentru o mai buna stratificare a riscului si identificarea de noi optiuni terapeutice in infarctul de miocard
Perioada: Iulie 2018 - Iunie 2022
Director de proiect: Acad. Maya Simionescu

4. Programul Operaţional Competitivitate, Axa prioritară 1: Cercetare, dezvoltare tehnologică şi inovare (CDI) în sprijinul competitivităţii economice şi dezvoltării afacerilor
Tip proiect: Atragerea de personal cu competențe avansate din străinătate pentru consolidarea capacității de CD, Contract nr.115/2016
Titlul proiectului: Terapii tintite pentru boala valvei aortice in diabet (THERAVALDIS)
Perioada: Septembrie 2016 - Decembrie 2020
Director de proiect: Dr. Agneta Simionescu

5. PNCDI III, Programul 1 - Dezvoltarea sistemului national de cercetare dezvoltare
Tip proiect: Proiecte de cercetare pentru stimularea tinerelor echipe independente, Contract nr. 51/2018
Titlul proiectului: Strategie preclinica pentru reducerea inflamatiei vasculare si stresului oxidativ in ateroscleroza prin modularea unor noi mecanisme moleculare dependente de ARN necodant
Perioada: Mai 2018 - Iulie 2020
Director de proiect: Dr. Adrian Manea

6. PNCDI III, Programul 4 - Cercetare fundamentala si de frontiera

Tip proiect: Proiecte de cercetare exploratorie, Contract nr. 69/2017
Titlul proiectului: Noi mecanisme epigenetice implicate in activarea macrofagelor antiinflamatorii - potentiale tinte terapeutice in ateroscleroza
Perioada: Iulie 2017 - Decembrie 2019
Director de proiect: Acad. Maya Simionescu

7. PNCDI III, Programul 2 - Cresterea competitivitatii economiei romanesti prin cercetare, dezvoltare si inovare
Tip proiect: Proiect experimental - demonstrativ, Contract nr. 137/2017
Titlul proiectului: Metoda neinvaziva bazata pe nanotehnologie pentru imagistica moleculara a stresului oxidativ in bolile cardiovasculare
Perioada: Ianuarie 2017– Septembrie 2018
Director de proiect: Dr. Adrian Manea

8. PNII IDEI, Contract nr. 107/2011
Titlul proiectului: Mecanisme moleculare implicate in reglarea stresului oxidativ in ateroscleroza: dezvoltarea unor nanocomplexe functionale inovative pentru terapia antioxidanta
Perioada: Ianuarie 2012– Decembrie 2016
Director de proiect: Acad. Maya Simionescu

2.3. Rezultate și discuții ... *107*

2.3.1. ADAMTS1, MMP-1, MMP-3, MMP-9 şi urokinaza sunt eliberate în mediul condiţionat ca urmare a interacției dintre CMN-MØ ... 107

2.3.2. Evaluarea expresiei MMP în interacția CMN cu MØ în condiții diabetice ... 109

2.3.3. Expresia de MMP-1 și MMP-9 este reglată prin CCR2 și NF-kB în CMN interacţionate cu macrofage în condiții de glucoză crescută ... 110

2.3.4. PKCα reglează expresia MMP-1 şi MMP-9 în CMN interacţionate cu macrofage în condiții de glucoză crescută ... 112

2.3.5. Evaluarea funcţională a capacității CMN de a forma fibre de colagen în condiţii de glucoză crescută ... 113

2.4. Concluzii *115*

3. **DIABETUL TIMPURIU INDUCE REMODELAREA MATRICEI ȘI MODIFICĂRI FUNCȚIONALE ÎN VALVA AORTICĂ ÎNTR-UN MODEL MURIN DE ATEROSCLEROZĂ ȘI ÎNTR-UN MODEL DE CULTURĂ CELULARĂ TRIDIMENSIONALĂ** 117

3.1. Introducere *117*

3.2. Materiale și metode *120*

3.2.1. Model șoarece diabetic hiperlipemic ApoE$^{-/-}$ 120

3.2.2. Colorații histochimice 121

3.2.3. Măsurarea parametrilor plasmatici 122

3.2.4. Imunofluorescență 123

3.2.5. Cuantificarea semi-cantitativă a imaginilor de imunofluorescență 124

3.2.6. Obținerea celulelor primare valvulare 124

3.2.7. Model de Cultură Celulară Tridimensională 125

3.2.8. qPCR 125

3.2.9. Western Blot 126

3.2.10. Analiza statistică 127

3.3. Rezultate și discuții *128*

3.3.1. Șoarecii menținuți pe dietă hiperlipemică prezintă nivele crescute ale glicemiei, prezintă modificări ale țesutului conjunctiv și dezvoltă depozite lipidice la nivelul valvei aortice 128

3.3.2. Hiperglicemia modifică fenotipul celulelor valvulare, inducând expresia markerilor de activare valvulari 132

3.3.3. Expresia moleculelor țesutului conjunctiv valvular nu este modificată în valva aortică a șoarecilor ApoE$^{-/-}$ hiperlipemici cu diabet timpuriu 134

3.3.4. Expresia moleculelor care reglează homeostazia și remodelarea matricei extracelulare dar și a motilității celulare 136

3.3.5. Expresia moleculelor implicate în remodelarea tisulară se corelează cu markerii de remodelare și calcificare, indicii plasmatici și hemodinamici 138

3.3.6. Dezvoltarea unui model 3D de foiță valvulară 140

3.3.7. Expunerea modelului 3D la concentrație crescută de glucoză modulează moleculele de matrice extracelulară exprimate de VIC 141

3.3.8. În modelul 3D de foiță valvulară, MMP-1 și MMP-13 sunt induse semnificativ de concentrația crescută de glucoză în VIC 144

3.3.9. Subunitățile integrinice α și β sunt modulate de concentrația crescută de glucoză în ambele tipuri de celule valvulare din modelul 3D 145

3.4. Concluzii *148*

4. **ANALIZA BIOINFORMATICĂ A COMUNICĂRII DINTRE CELULELE VALVULARE ÎNTR-UN MODEL DE ȘOARECE DEFICIENT IN APOE** 149

4.1. Introducere *149*

4.2. Metode *150*

4.2.1. Procesarea și analiza datelor de sc-RNAseq 150

4.2.1.1. Controlul calității datelor 151

4.2.1.2. Normalizarea datelor 154

4.2.1.3. Integrarea datelor 154

4.2.1.4. Vizualizarea datelor – analiza de tip PCA și proiecția UMAP 155

4.2.1.5. Gruparea celulelor 158
4.2.2. Analiza de expresie genică diferențială 158
4.2.3. Analiza îmbogățirii setului de gene - GSEA 159
4.2.4. Analiza NicheNet pentru modelarea comunicației intercelulare 160
4.2.4.1. Definirea unui set de gene de interes și a unei populații receptor 160
4.2.4.2. Definirea genelor exprimate în populațiile expeditor 161
4.2.4.3. Definirea unor potențiali liganzi și calcularea activității liganzilor în setul de gene de interes 161
4.2.4.4. Determinarea genelor țintă și a receptorilor pentru liganzii de top clasificați în analiza NicheNet 162
4.2.4.5. Calcularea expresiei diferențiale a liganzilor în celulele expeditor în condiția Apoe$^{-/-}$ vs control 162
4.3. Rezultate și discuții 163
4.3.1. Analiza sc-RNAseq a celulelor valvulare în șoarecele control și în șoarecele Apoe$^{-/-}$ 163
4.3.1.1. Analiza sc-RNAseq arată existența a 14 grupuri de celule valvulare atât în șoarecele control cât și în cel Apoe$^{-/-}$ 163
4.3.1.2. Determinarea genelor care definesc grupurile celulare identificate la nivelul valvei aortice murine 165
4.3.1.3. Determinarea genelor definitorii pentru grupurile de macrofage 170
4.3.1.4. Determinarea genelor definitorii pentru celulele valvulare interstițiale 176
4.3.2. Analiza diferențială a expresiei genice în grupurile de VIC și macrofage în condiția Apoe$^{-/-}$ versus control (C57BL/6J) 186
4.3.2.1. Expresia diferențială a genelor din grupul Mac Lyve1^{+} în șoarecele hiperlipidemic 186
4.3.2.2. Expresia diferențială a genelor din grupul Mac CD11c^{+} în șoarecele hiperlipidemic 188
4.3.2.3. Expresia diferențială a genelor din grupul VIC Meox1^{+} în șoarecele hiperlipidemic 192
4.3.2.4. Expresia diferențială a genelor din grupul VIC Clec3b^{+} în șoarecele hiperlipidemic 195
4.3.2.5. Expresia diferențială a genelor din grupul VIC Spp1^{+} în șoarecele hiperlipidemic 197
4.3.3. Analiza îmbogățirii setului de gene (GSEA) pentru genele modificate în grupul VIC Spp1^{+} sugerează că hiperlipidemia induce în principal modificări ale matricei extracelulare și a genelor implicate în formarea de fibre de colagen 202
4.3.4. Modelarea comunicării inter-celulare în valva aortică murină și efectul acesteia asupra genelor clusterului VIC Spp1^{+} modificate în condiția hiperlipidemică 205
4.3.4.1. .Determinarea liganzilor potențiali care pot să explice modificările observate în VIC Spp1^{+} 206
4.3.4.2. Determinarea potențialului reglator al liganzilor prezișI în analiza NicheNet 206
4.3.4.3. Nivelul expresiei genice a liganzilor prezișI de analiza NicheNet în clusterele de celule valvulare 211
4.3.4.4. Modificarea expresiei genice a liganzilor cu potențial de reglare a VIC Spp1+ în condiția Apoe$^{-/-}$ 213
4.3.4.5. Determinarea principalilor receptori exprimați pe suprafața VIC care pot interacționa cu liganzii identificați de analiza NicheNet 214
4.4. Concluzii 216
IV. CONCLUZII GENERALE 218
V. BIBLIOGRAFIE 223

Introducere

Bolile cardiovasculare reprezintă principala cauză de mortalitate în țările dezvoltate (Organization, 9 December 2020) acestea se mențin în topul acestei statistici datorită expunerii tot mai frecvente a omului modern la factorii de risc pentru bolile cardiovasculare. Acești factori de risc includ: fumatul, dieta nesănătoasă, lipsa activității fizice, hiperlipidemia, hipertensiunea, expunerea la poluare, consumul de alcool, obezitatea și nu în ultimul rând diabetul. Diabetul zaharat este cel mai răspândit sindrom metabolic și complicațiile asociate cu acesta sunt majoritar macro- și micro-vasculare conducând la nefropatie, retinopatie și neuropatie ca urmare a accelerării procesului aterosclerotic.

Bolile cardiovasculare cuprind un număr mare de patologii printre care: insuficiența cardiacă, valvulopatiile cardiace și aritmiile, boala cardiacă reumatică (leziuni ale miocardului și valvelor cardiace cauzate de infecția cu *Streptococcus pyogenes*), malformațiile cardiace congenitale, tromboza venoasă profundă cu propria sa complicație, embolia pulmonară și nu în ultimul rând ateroscleroza care prezintă două complicații majore, infarctul miocardic și accidentul vascular cerebral ischemic (Thiriet, 2018).

Ateroscleroza este cea mai importantă patologie subiacentă bolii arteriale coronare, bolii arteriale periferice și a bolilor cerebrovasculare. Fiind o boală a arterelor mari și medii, ateroscleroza presupune acumularea în spațiul subendotelial a lipoproteinelor, în special a lipoproteinelor de densitate mică (LDL), a celulelor imune, dar și a celulelor musculare netede (CMN), acumulare care în timp formează plăci ocluzive care la rândul lor determină stenoza arterială. CMN pe parcursul dezvoltării aterosclerozei produc o serie de proteine de matrice extracelulare (MEC) cum ar fi colagen, elastină, dar și porteoglicani și glicozamino glicani, care contribuie la îngroșarea spațiului sub-intimal dar și la menținerea unui cap fibros. Pe măsură ce placa avansează CMN pot suferi o metaplazie în celule spumoase care înglobează LDL, suferă apoptoză, iar acest conglomerat de resturi celulare împreună cu deficiență a eferocitozei de către macrofage (MØ), conduce la formarea unui miez necrotic. Toți acești factori determină în același timp și creșterea și cronicizarea inflamației și astfel a recrutării macrofagelor care secretă o serie de metaloproteinaze matriceale (MMP) cu rol în degradarea MEC, ceea ce determină o subțiere a capului fibros și determină o predispoziție la rupere a acestuia. Astfel, dacă acumularea inițială de LDL și formarea capului fibros duc la îngustarea arterelor care restricționează fluxul sangvin determinând ischemie și hipoxie tisulară (Wolf and Ley, 2019), ruperea capului fibros determină formarea de trombi care pot

bloca complet arterele determinând în cazul arterelor coronare, infarctul de miocard, iar în cazul arterelor cerebrale, atacul vascular cerebral.

O altă boală cardiovasculară care afectează un număr tot mai însemnat de oameni este **boala valvei aortice (BVA)** (Coffey et al., 2021). Valva aortică este una dintre cele 4 valve care controlează fluxul sangvin în inimă, ea separă ventriculul stâng de aortă. Bolile care afectează această valvă afectează circulația sângelui și se împart în două categorii: stenoza aortică - boală care îngustează orificiul valvular, îngreunând fluxul sangvin și insuficiența (regurgitarea aortică) – boală care determină o închidere incompletă a valvei în diastolă. Cea mai frecventă afecțiune a valvei aortice este stenoza aortică determinată de calcificarea valvei, afecțiune denumită în continuare boala valvei aortice (BVA). Ea este caracterizată de îngroșarea, fibroza și mineralizarea cuspelor aortice. Analiza foițelor aortice a arătat că mineralizarea distrofică și tranziția osteogenică a celulelor valvulare interstițiale (VIC) apar concomitent cu neovascularizarea, microhemoragia și producția anormală de matrice extracelulară (Moncla et al., 2023). Factorii de risc pentru BVA pot fi împărțiți în două categorii, factori de risc care nu pot fi modificați, si anume: vârsta și morfologia bicuspidă congenitală a valvei aortice și factori de risc care pot fi ameliorați ca: tensiunea arterială crescută, nivelul de colesterol din plasmă și prezența obezității și a diabetului zaharat. Interacțiuni complexe între celulele endoteliale și interstițiale ale valvei și celulele imune promovează remodelarea valvei aortice și dezvoltarea BVA. Deoarece, până în prezent nici un tratament medical nu a fost eficient în reducerea sau prevenirea progresiei BVA, studiile care au ca scop identificarea unor posibile ținte terapeutice sunt deosebit de importante.

Impactul bolilor cardiovasculare este în creștere și datorită ratei de creștere a obezității și a diabetului. **Diabetul** este cea mai răspândită boala metabolică, iar povara sa medicală și socio-economică este dată de complicațiile asociate, în special la nivel macrovascular și microvascular. Acestea conduc la retinopatie, neuropatie și nefropatie, ca urmare a accelerării aterogenezei. S-a demonstrat anterior că ambele tipuri de diabet zaharat pot induce dezvoltarea aterosclerozei sau accelerează și mai mult progresia acesteia (Katakami, 2018). Nivelul crescut de glucoză, dislipidemia dar și alte modificări metabolice care însoțesc diabetul sunt strâns legate de patogeneza aterosclerozei. Iar inflamația cronică este prezentă încă de la primele stadii ale inițierii diabetului și este considerată în prezent ca unul dintre factorii cheie în dezvoltarea aterosclerozei (Wolf and Ley, 2019).

În patologia aterosclerozei și a BVA apar transformări semnificative ale **matricei extracelulare**. Matricea extracelulară asigură un cadru vital pentru țesutul vascular și

valvular, având rolul unui schelet ce susține organizarea și homeostazia celulelor. MEC este un ansamblu complex de macromolecule, având impact asupra comportamentului celulelor, promovând diferențierea, migrarea și proliferarea prin intermediul interacțiunilor specifice dintre celule și matrice. Mai mult, MEC ajută și la comunicarea intercelulară, are un rol important în motilitatea, dezvoltarea celulară și repararea țesuturilor lezate, de asemenea acționează și ca un depozit de factori de creștere și molecule bio-active care pot fi eliberate (Silva et al., 2020).

În acest context, studiu de față pornește de la **ipoteza** că inflamația și comunicarea dintre celulele imune și celulele rezidente vasculare (CMN) și valvulare (VIC) poate conduce la modificări patologice ale MEC prin mecanisme celulare și moleculare specifice, iar această remodelare patologică este accelerată în ateroscleroza în condiții de diabet.

Lucrarea de față a fost structurată în două părți principale, o primă secțiune denumită „Stadiul actual al cunoașterii" care explorează literatura existentă privind ateroscleroza, boala valvulară aortică, diabet și impactul acestor patologii asupra matricei extracelulare.

O**biectivul principal** al tezei a fost reprezentat de investigarea mecanismelor celulare și moleculare a remodelării MEC în ateroscleroză și a BVA în contextul diabetului. Rezultatele originale obținute sunt prezentate în a doua secțiune a lucrării, denumită „Contribuții originale" care este structurată în 4 capitole.

Contribuții originale

Capitolul 1 - "Comunicarea dintre celulele musculare netede şi macrofage accelerează evoluția plăcii aterosclerotice către placă vulnerabilă și ruperea plăcii prin inducerea mediatorilor inflamatorii" - a vizat investigarea comunicării patologice dintre CMN și MØ în contextul aterosclerozei.

Contextul patologic al aterosclerozei surprinde o interacțiune între CMN și macrofage care nu este de obicei întâlnită în condiții de homeostazie vasculară. CMN sunt rare în intima arterială și sunt prezente în principal în media arterelor mari de unde migrează către zone unde există infiltrări de LDL și inflamație locală. În aceste zone, ele interacționează cu macrofagele recrutate din circulație în spațiul sub-endotelial și suferă modificări fenotipice care favorizează evoluția aterosclerozei. Ca răspuns la semnalele din micromediul vascular, MØ suferă un proces de polarizare spre macrofage proinflamatoare

(M1) sau anti-inflamatoare (M2) şi induc un fenotip pro-aterogenic în CMN vasculare (Butoi et al., 2011). De asemenea, fenotipul CMN poate influenţa balanţa dintre populaţiile de macrofage M1 sau M2, determinând astfel progresia plăcii aterosclerotice. În placa aterosclerotică, MØ şi CMN pot interacţiona direct - prin molecule exprimate pe suprafaţa celulară (ICAM-1, VCAM-1 şi CX3CL1) şi receptorii lor - sau indirect, prin factori solubili (chemokine şi citokine), care pot modifica fenotipul ambelor tipuri celulare, influenţând astfel evoluţia leziunii aterosclerotice (Manduteanu and Simionescu, 2012).

Anterior, grupul nostru a demonstrat inducerea expresiei unui număr mare de citokine și chemokine în macrofage în urma interacției cu CMN, aceşti mediatori inflamatori amplificând chemotaxia monocitelor (Tucureanu et al., 2016). De asemenea, grupul nostru a arătat că interacția dintre MØ și CMN afectează expresia colagenului I și III, crește sinteza metaloproteazei MMP-9 și promovează angiogeneza, caracteristici care pot contribui la vulnerabilitatea plăcii (Butoi et al., 2016).

În studiul de faţă, pentru a investiga contribuţia comunicării dintre macrofage şi CMN în agravarea leziunii aterosclerotice, am investigat mediatorii inflamatori induşi de interacţia CMN-MØ, modificarea fenotipică a CMN în urma interacţiei celulare şi căile de semnalizare implicate în comunicarea dintre CMN-MØ.

Modelul experimental folosit în acest capitol a fost un model *in vitro* care a presupus o cameră dublă Boyden cu macrofage diferențiate, în camera superioră, pe un insert cu pori de 4 μm și CMN însămânțate în camera de jos. Metodele de studiu au inclus tehnici de western blot (WB), teste imunosorbent legat de enzime (ELISA), protein array și reacția cantitativă de polimerizare în lanț în timp real (qPCR).

Rezultatele acestui capitol au arătat că interacția indirectă a CMN cu macrofagele induce secreția de mediatori inflamatori precum: G-CSF, GM-CSF, ICAM-1, IL-6, CCL5.

Interacţia dintre CMN-MØ modifică fenotipul normal al CMN (Figura 1) prin scăderea α-SMA, ceea ce poate determina o scădere a capacității contractile. Totuși fenotipul CMN nu este unul pro-osteoblastic deoarece nivelul de osteopontină este și el scăzut în interacție.

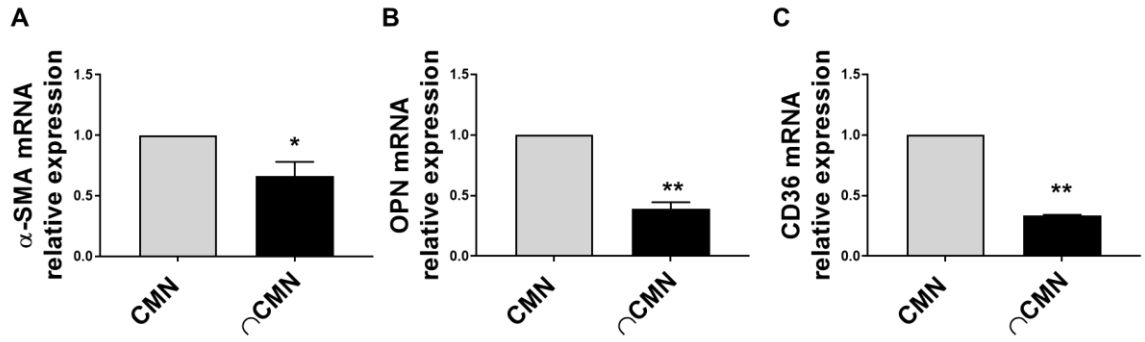

Figura 1 *Expresia genică a markerilor fenotipici ai CMN este scăzută în urma interacţiei cu MØ. Expresia genică a αSMA (A), osteopontinei (OPN) (B) şi CD36 (C) a fost determinată prin RealTime PCR în CMN interacţionate cu MØ (∩CMN) sau CMN control.*

Interacţia CMN-MØ induce expresia citokinei IL-6 (Figura 2) şi a chemokinei CCL5 (Figura 3) în CMN, molecule cu rol important în progresia plăcii aterosclerotice.

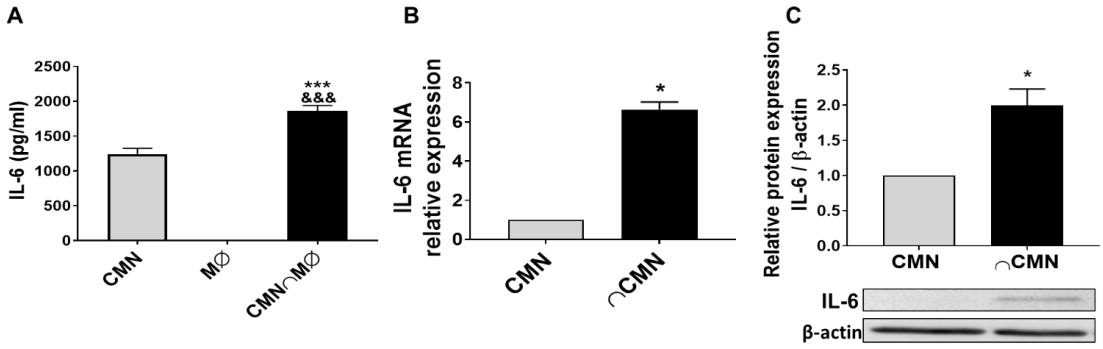

Figura 2 *Secreţia şi expresia IL-6 este crescută în CMN în urma interacţiei cu macrofagele.*

Se cunoaşte faptul că migrarea CMN în intima peretelui vascular este ghidată de chemokinele secretate de celulele imune şi rezidente în placa aterosclerotică (Tedgui and Mallat, 2006). CCL5 (RANTES) este o chemokină cu rol esenţial în procesul inflamator, prin recrutarea celulelor imune la locul inflamaţiei. Expresia CCL5 este crescută în celulele peretelui vascular iar blocarea legării CCL5 la receptorul său (CCR5) a arătat o reducere a formării plăcii aterosclerotice şi prevenirea progresiei leziunilor aterosclerotice la şoareci (Liu et al., 2012).

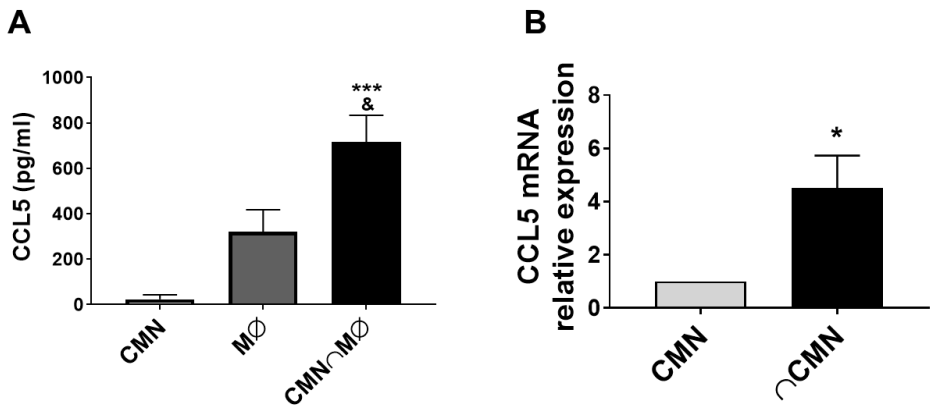

Figura 3 *Secreţia şi expresia CCL5 este crescută în CMN în urma interacţiei cu macrofagele.*

Activarea căilor de semnalizare MAPK (protein kinaze activate de mitogen) a fost demonstrată în ateroscleroză, fiind cunoscut faptul că ERK1/2, JNK şi p38 MAPK sunt activate în CMN implicate în procesul patologic (Pan et al., 2023). Astfel, în CMN interacţionate cu MØ, am analizat activarea căilor MAPK prin detecţia formelor fosforilate ale ERK1/2, JNK şi p38 prin tehnica Western Blot. Datele noastre au arătat că interacţia CMN-MØ induce activarea căii ERK1/2 în CMN după 6 ore de interacţie, demonstrată prin creşterea semnificativă (de 2,7 ori) a proteinei fosfo-ERK1/2, raportată la proteina totală ERK1/2; după 24 ore de interacţie cu macrofagele, calea ERK nu mai este activată în CMN.

Caspaza-1 este proteina efector a inflamazomului NLRP3, care clivează proforma citokinelor inflamatoare, generând forma lor activată, care este eliberată. În condiţiile noastre experimentale, NLRP3 nu este exprimat în CMN control sau interacţionate cu macrofage, deşi expresia proteică a IL-1β este semnificativ crescută, ceea ce confirmă datele noastre anterioare (Butoi et al., 2016). În schimb, expresia proteică a caspazei-1 este semnificativ crescută în CMN interacţionate timp de 24 ore cu macrofage.

Rezultatele obținute pe MØ în interacţia cu CMN au arătat o creştere a expresiei de MIP-1β (Figura 4) care se cunoaște că are un rol important în progresia bolii aterosclerotice şi vulnerabilitatea plăcii (Chang and Chen, 2016).

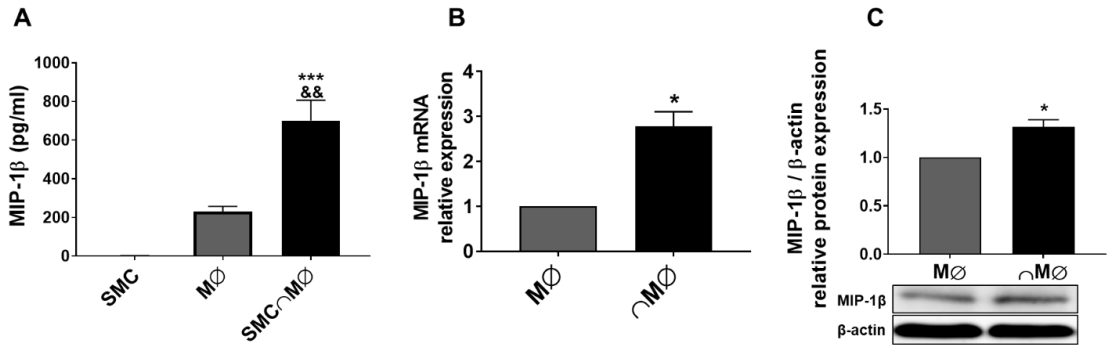

Figura 4 *Secreţia şi expresia MIP-1β este crescută în macrofage în urma interacţiei cu CMN.*

Ţinând cont de faptul că MIP-1β se găseşte la un nivel crescut în serul pacienţilor cu plăci aterosclerotice avansate şi este un predictor independent al evenimentelor cardiovasculare majore (Chang and Chen, 2016), datele noastre sugerează contribuţia importantă a comunicării dintre macrofage şi CMN în agravarea leziunii prin creşterea expresiei şi secreţiei de MIP-1β.

Căile de semnalizare activate în MØ în urma comunicării cu CMN sunt reprezentate de calea ERK1/2, însă nu se observă și activarea p38 și JNK MAPK. În plus a fost observată activarea inflamazomului NLRP3.

Aceste date contribuie la înţelegerea modului în care comunicarea între CMN şi macrofage amplifică procesul inflamator în placa aterosclerotică.

Al doilea capitol intitulat **- Diabetul accentuează remodelarea matricei extracelulare indusă de comunicarea celulelor musculare netede cu macrofagele -** evidențiază modularea enzimelor de remodelare a MEC – MMP – induse de comunicarea dintre CMN și MØ în condiții de glucoză crescută.

Rolul CMN în progresia aterosclerozei este complex, însă acesta este considerat în principal benefic, prin secreția de elemente de matrice, și în special de colagen de tip I, care poate stabiliza placa aterosclerotică formând un cap fibros. Pe de altă parte macrofagele au un efect opus, ele secretând o serie de enzime de remodelare a matricei care au un efect pro-trombotic prin subțierea acestui cap fibros.

Date obținute pe modele experimentale animale prin analiza histologică a regiunilor predispuse la rupere ale plăcii aterosclerotice, au arătat niveluri crescute de MMP-1, MMP-3 şi MMP-9 (Newby, 2005). Pierderea fibrelor de colagen și a altor componente ale MEC se

produce în regiunile cu o inflamație crescută în capul fibros. Studii recente au sugerat că plăcile aterosclerotice ale pacienților cu diabet de tip II sunt mai predispuse la rupere datorită creșterii inflamației vasculare și a răspunsului reparator ineficient (van Diepen et al., 2016, Edsfeldt et al., 2014). Totuși, moleculele cheie implicate în progresia plăcii spre o placă vulnerabilă la pacienții diabetici nu sunt cunoscute.

Datele din prezenta lucrare continuă studiile anterioare ale grupului nostru, unde am arătat că interacția dintre CMN și MØ produce o serie de molecule inflamatorii cum sunt MCP-1 și IL-1β, molecule care determină activarea macrofagelor și o modificare fenotipică a CMN caracterizată de expresia crescută a MMP-1, -2 și -9 și scăderea expresiei colagenului de tip I și III (Butoi et al., 2016). Silențierea CX3CR1, receptorul pentru fractalkină, a indus scăderea nivelului de MMP-9, sugerând implicarea acestuia în comunicarea celulară patologică (Butoi et al., 2011).

Folosind modelul *in vitro* de co-cultură stabilit anterior, am utilizat metode clasice de WB, protein array, qPCR, o metodă de vizualizare a asamblării de colagen dar și inhibatori farmacologici sau acid ribonucleic (ARN) de interferență pentru a determina contribuţia comunicării dintre macrofage şi CMN în progresia bolii aterosclerotice spre o placă vulnerabilă predispusă la ruptură.

Astfel, rezultatele prezentate în acest capitol au arătat că interacția CMN și MØ induce eliberarea în mediul condiţionat a unor proteaze cum sunt: ADAMTS1, MMP-1, MMP-3, MMP-9 şi urokinaza. Expresia proteică a MMP-1 și -9 este semnificativ crescută în CMN după co-cultură cu MAC umane derivate din monocite proaspăt izolate de la pacienți diabetici (ScDM) comparativ cu MAC control (ScCM). Pentru a determina efectul co-cultivării CMN cu MAC diabetice sau al concentraţiilor crescute de glucoză (HG) asupra MMP-urilor produse de CMN în urma interacţiei, ambele tipuri de MAC derivate de la donatori sănătoși (CM) sau de la pacienți diabetici (DM), au fost co-cultivate în condiții normale (NG) sau HG cu CMN. Se observă că MMP-9 a fost exprimat în CMN interacţionate cu CM în HG comparativ cu NG și de asemenea în CMN co-cultivate cu DM în HG comparativ cu NG, sugerând efectul glucozei crescute asupra expresiei MMP-9 (**Error! Reference source not found.**A). În plus, expresia MMP-9 este mai mare în CMN care au fost co-cultivate în HG cu DM comparativ cu CM, indicând faptul că MAC diabetice sunt responsabile pentru creșterea expresiei MMP-9. În cazul MMP-1, principala cauză a creșterii expresiei este concentrația crescută de glucoză, deoarece nu au fost obținute diferențe semnificative între expresia MMP-1 în CMN co-cultivate cu CM sau DM atunci când au fost expuse la condiții HG (Figura 5).

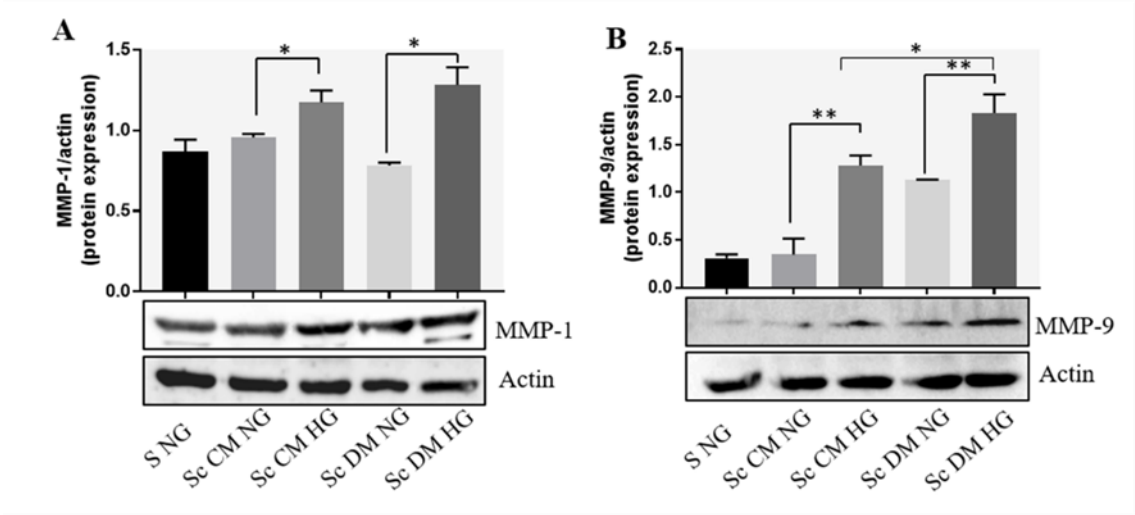

Figura 5 *Expresia proteică a MMP-1* ***(A)*** *şi MMP-9* ***(B)*** *în CMN în mediu cu concentraţii normale (NG) sau cresute (HG) de glucoză, neinteracţionate (S) sau interacţionate (Sc) cu macrofage diferenţiate din monocite izolate de la pacienţi control (CM) sau pacienţi diabetici (DM). Expresia proteică a MMP-1 şi MMP-9 a fost normalizată la expresia de β-actină, (Macarie et al, 2018, J.Cel.Mol.Med).*

Pentru a evidenția căile de semnalizare implicate în această creștere a enzimelor de remodelarea a MEC am realizat silențierea receptorului pentru MCP-1 – Ccr2 și a sub-unității p65 a NF-kB prin transfectarea CMN cu ARN de interferență înainte de co-cultivarea cu MØ. Aceste experimente (Figura 6) au arătat că expresia proteică a MMP-1 și MMP-9 a fost semnificativ redusă în CMN în care CCR2 și p65 au fost silenţiate. Nu a fost detectat niciun efect asupra expresiei MMP-urilor în CMN transfectate cu siRNA nespecific (control negativ).

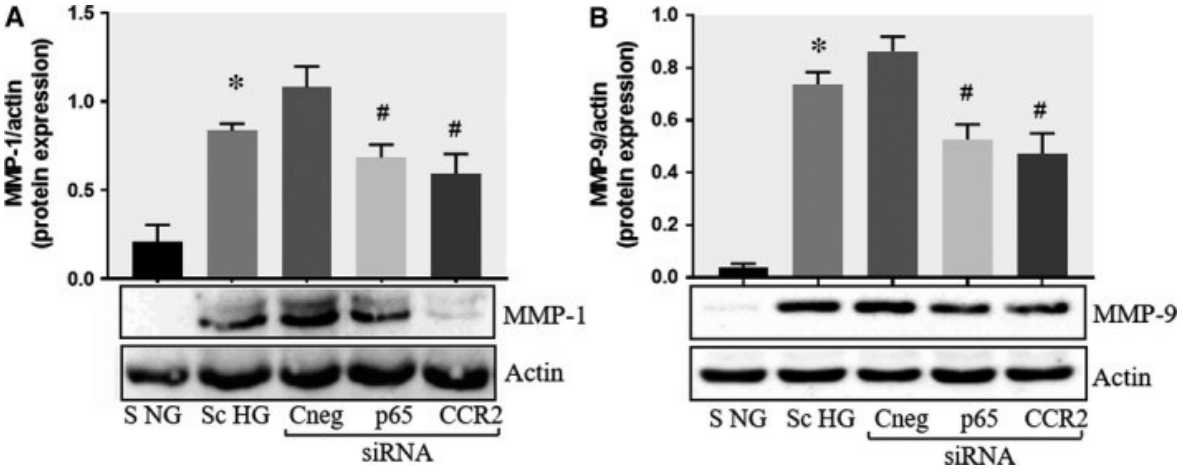

Figura 6 *Efectul silenţierii CCR2 şi p65 în reglarea expresiei MMP-1 şi MMP-9 în CMN. Expresia MMP-1 (A) şi MMP-9 (B) a fost determinată prin Western Blot în CMN control (S NG), CMN co-cultivate cu MØ în condiţii de glucoză crescută (Sc HG) şi CMN silenţiate pentru CCR2 şi p65, interacţionate cu MØ în condiţii de glucoză crescută (Cneg, p65, CCR2 siRNA). (Macarie et al, 2018, J.Cel.Mol.Med)*

Activarea protein kinazei C (PKC) este unul dintre evenimentele principale de semnalizare induse de concentrația crescută de glucoză. Pentru a examina posibila implicare a PKC în creșterea expresiei de MMP-1 și MMP-9, am evaluat activarea PKCα în CMN. După cum rezultă din experimentele de Western Blot, co-cultura CMN-MØ în condiții de glucoză crescută a indus o creștere semnificativă a fosforilării PKCα în CMN. Interesant, silențierea p65 sau CCR2 cu siRNA specific a împiedicat activarea PKCα.

Pentru a evalua dacă PKCα este implicată direct în expresia de MMP-1 și MMP-9, co-cultura dintre CMN-MØ a fost realizată în prezența inhibitorului de PKCα, Go 6976 (1 μmol/L). În acest caz, expresia proteică a ambelor proteaze, MMP-1 și MMP-9, a fost semnificativ redusă, sugerând că activarea PKCα este implicată în supraxpresia MMP-1 și MMP-9 (Figura 7).

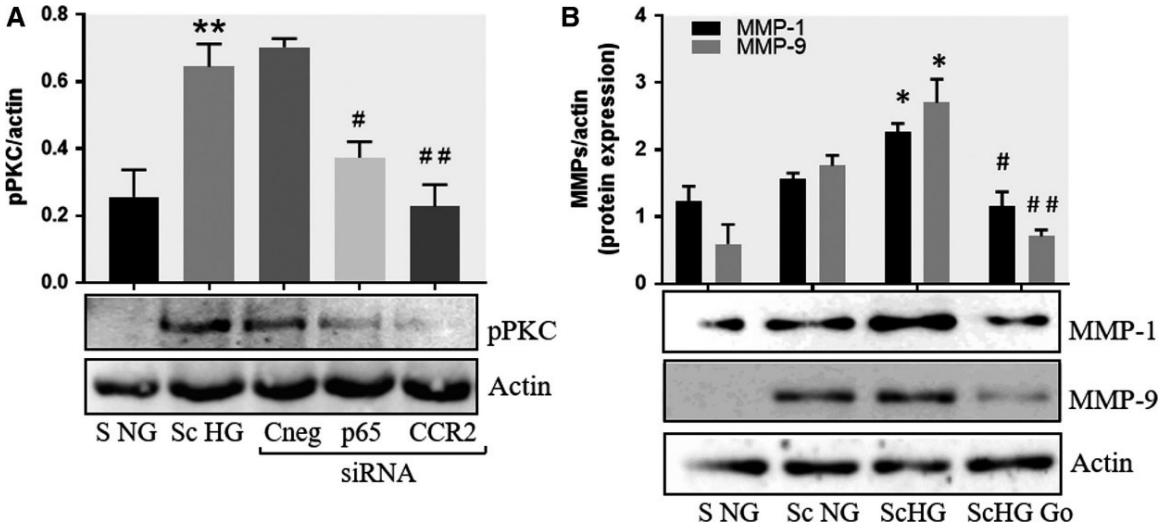

Figura 7 *Inhibarea PKCα scade expresia proteică a MMP-1 şi MMP-9 indusă de interacţia CMN cu MØ.* ***(A)*** *Evaluarea activării PKCα în CMN control (S NG) comparativ cu CMN co-cultivate cu MØ în condiţii de glucoză crescută (Sc HG). Forma fosforilată a PKCα este semnificativ crescută în Sc HG. Silenţierea CCR2 sau p65 scade activarea PKCα la nivelul controlului.* ***(B)*** *Efectul inhibitorului PKCα (Go 6976) asupra expresiei proteice de MMP-1 şi MMP-9 indusă de comunicarea CMN-MØ. (Macarie et al, 2018, J.Cel.Mol.Med)*

În continuare, am investigat dacă CMN activate de interacţia cu macrofagele îşi păstrează capacitatea de a forma fibrile de colagen, o caracteristică importantă în stabilitatea vasculară (Li et al., 2003). Pentru aceasta, colagenul solubilizat şi marcat cu Texas Red a fost adăugat în cultura de CMN control sau CMN după interacţia lor cu macrofage în condiţii de glucoză normală (NG) sau glucoză crescută (HG). Asamblarea fibrilelor de colagen a fost urmărită prin microscopie de fluorescenţă.

Rezultatele au aratat (Figura 8) că după interacţia cu MØ în condiţii normale sau crescute de glucoză, CMN îşi scad capacitatea de a asambla monomerii de colagen în fibre, comparativ cu CMN neinteracţionate, menţinute în mediu cu concentraţie normală de glucoză. Atunci când CMN interacţionate cu MØ în condiţii de glucoză crescută au fost preincubate pentru 3 minute cu anticorpi de blocare anti-MMP-1 sau anti-MMP-9, acestea şi-au recăpătat capacitatea de a asambla monomerii de colagen.

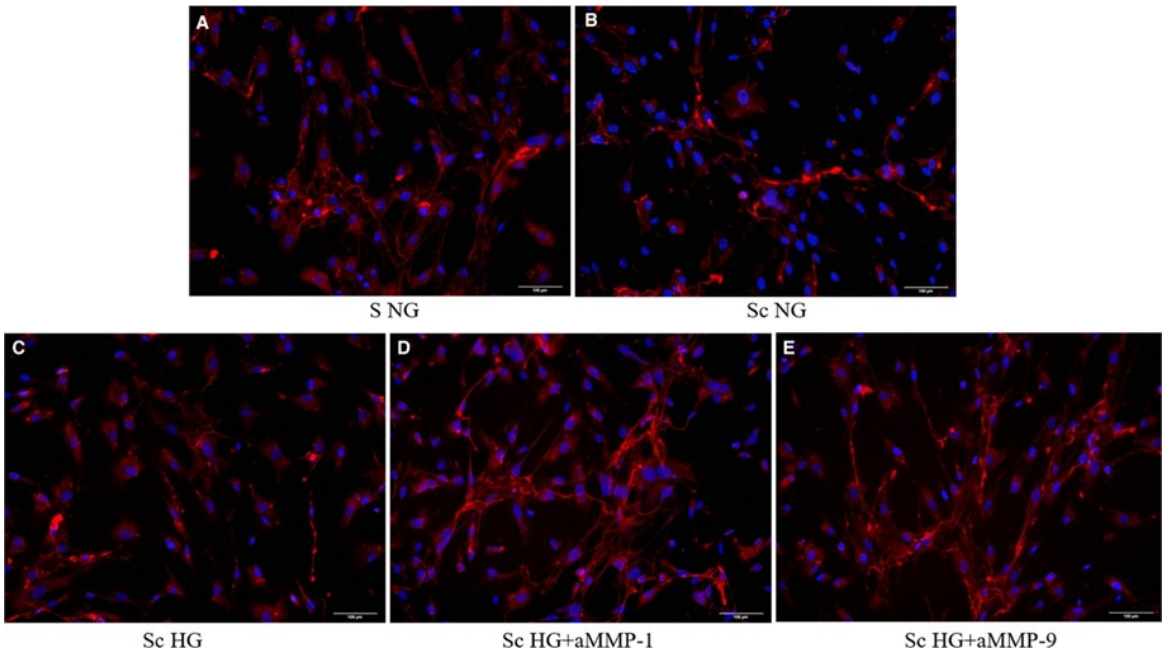

Figura 8 *Formarea fibrelor de colagen de către CMN, din colagen solubil marcat cu Texas Red. (Macarie et al, 2018, J.Cel.Mol.Med)*

Rezultatele acestor două capitole au vizat în principal ateroscleroza și au accentuat relevența comunicării intercelulare în procesele biologice, dar mai ales în condițiile patologice, unde echilibrul acestor interacțiuni poate fi complet dereglat. Astfel, am arătat că, macrofagele au un efect pro-inflamator și că CMN pot deveni la rândul lor mediatori ai inflamației locale conducând la cronicizarea inflamației. Totodată, concentrațiile crescute de glucoză modulează această interacțiune, determinând o secreție crescută a proteazelor matriceale și anomalii în procesul de asamblare a colagenului, modificări ce pot favoriza dezvoltarea unei plăci aterosclerotice susceptibilă la rupere.

Capitolul 3 - Diabetul timpuriu induce remodelarea matricei și modificări funcționale în valva aortică într-un model murin de ateroscleroză și într-un model de cultură celulară tridimensională - a avut ca obiectiv principal studiul bolii valvei aortice și a modificărilor MEC induse de diabetul timpuriu.

Integritatea structurală a MEC este esențială pentru funcția normală a valvei aortice, iar modificări ale acesteia au fost observate în toate stadiile patogenezei BVA. Diabetul accelerează evoluția BVA și poate induce modificări ale MEC. Totuși, modificările MEC induse de diabet în etapele timpurii ale evoluției BVA nu au fost studiate.

Acest capitol a abordat două modele experimentale de studiu, unul *in vivo* reprezentat de un șoarece deficient în apolipoproteina E (ApoE), căruia i-a fost indus diabetul prin injecții cu streptozotocină și care a fost apoi menținut pe o dietă bogată în colesterol pentru inducerea aterosclerozei și a modificărilor la nivelul valvei aortice; și un model *in vitro*, reprezentat de un model tridimensional de co-cultură bazat pe un hidrogel din gelatină metacrilată în care au fost înglobate celule valvulare umane și care a fost expus la concentrații crescute de glucoză. Metodele folosite în acest capitol au inclus: imunofluorescența, izolarea de celule primare valvulare umane, WB și qPCR.

Rezultatele acestui capitol 3 au arătat că *in vivo* diabetul experimental induce modificări ale elementelor de matrice și a enzimelor de remodelare cum ar fi colagenul 3, fibronectina, MMP-2 și MMP-9 (Figura 9).

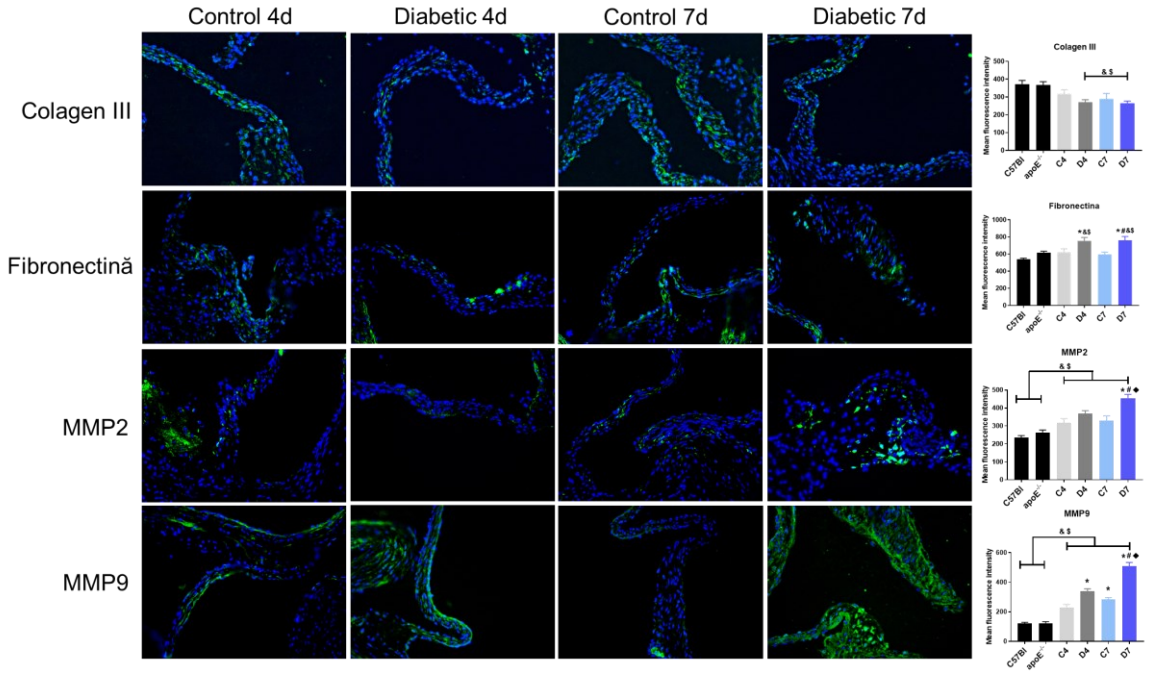

Figura 9 *Expresia proteică a proteinelor de matrice extracelulară: colagen III și fibronectină și a gelatinazelor MMP-2 și MMP-9. În dreapta imaginilor de imunofluorescență este analiza statistică a expresiei de MMP-2, -9, colagen III și fibronectină în grupurile de șoareci control și diabetici.*

Aceste modificări sunt corelate cu parametrii plasmatici și funcționali ai valvei aortice (Figura 10) astfel: nivelul crescut al MMP-9 se corelează pozitiv puternic cu parametrii plasmatici precum fetuina, trigliceride, colesterolul total și LDL, cu expresia markerului de miofibroblaste – αSMA, cu expresia unei alte metaloproteaze matriceale - MMP2 dar și cu parametrii funcționali ai valvei - velocitatea și VTI; fibronectina se asociază

pozitiv cu MMP-2 și MMP-9 și negativ cu colagenul III iar colagenul de tip III este corelat negativ cu αSMA, vimentina, MMP9, LDL și colesterolul total.

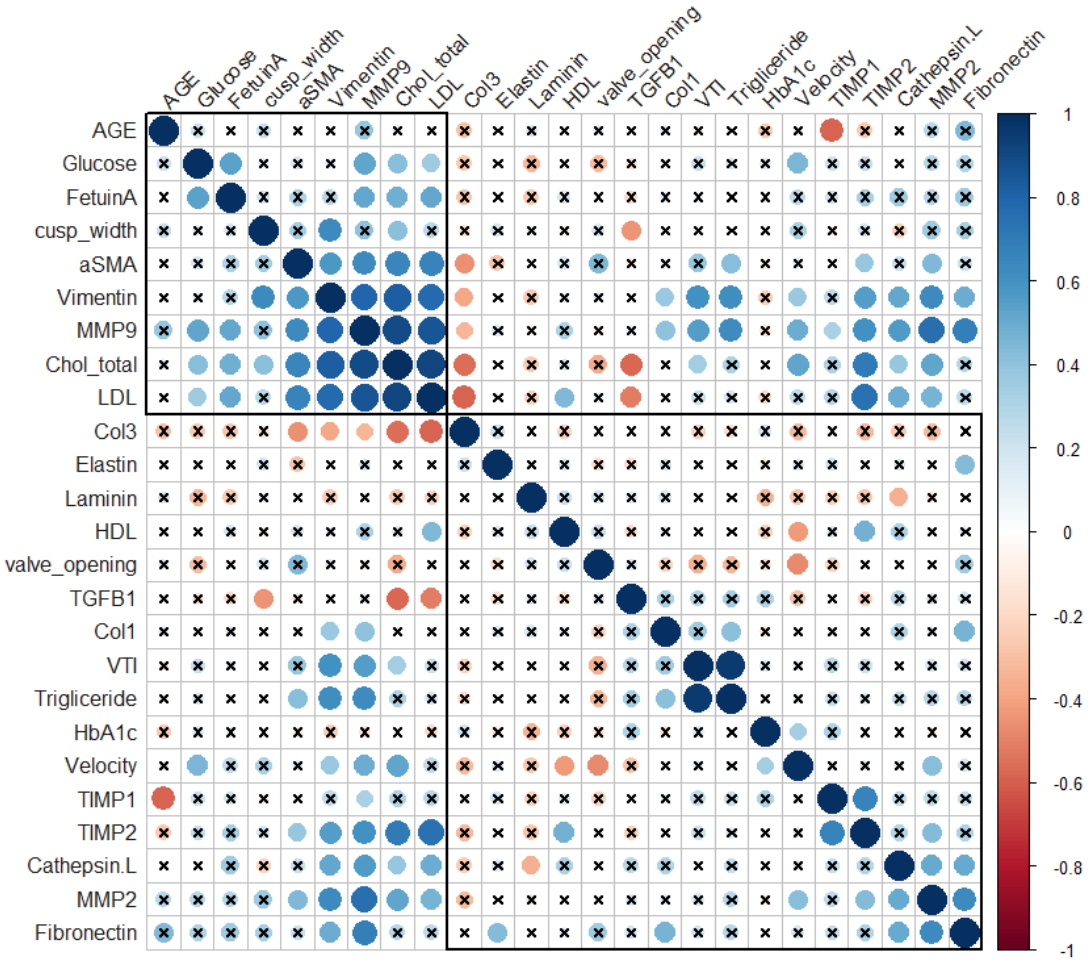

Figura 10 *Matricea corelațiilor Pearson dintre proteinele de matrice extracelulară, markerii de remodelare și parametrii funcționali și plasmatici ai valvei aortice. Valorile medii măsurate pentru fiecare grup experimental au fost utilizate pentru realizarea de corelații Pearson. Corelațiile pozitive sunt reprezentate prin culoarea albastru, corelațiile negative prin culoarea roșu iar paleta de culori din legendă indică coeficentul Pearson (r). Corelațiile care nu ating pragul de semnificație statistică (p > 0,05) sunt marcate cu un x (modificat după Țucureanu, et al., 2019).*

Pentru a identifica tipul celular afectat de condițiile hiperglicemice și pe cel responsabil de modificările observate asupra moleculelor asociate procesului de remodelare, studiul a continuat cu analiza efectelor glucozei asupra VEC și VIC într-un model 3D de foiță valvulară dezvoltat în laboratorul nostru (Vadana et al., 2020) și trimis spre brevetare. Modelul 3D dezvoltat în laboratorul nostru este obținut din hidrogel (gelatină metacrilată) și

are următoarele avantaje: i) respectă structura foiței valvulare native având VEC la exterior și VIC încapsulate în interior, și ii) celulele valvulare crescute în acest model sunt umane, ceea ce îi conferă o relevanță deosebită în ceea ce privește rezultatele obținute cu ajutorul lui.

Rezultatele obținute pe acest model au evidențiat modificări celulare specifice ale enzimelor de remodelare a MEC (Figura 11A) și ale receptorilor transmembranari care realizează legătura dintre celule și MEC (Figura 11B).

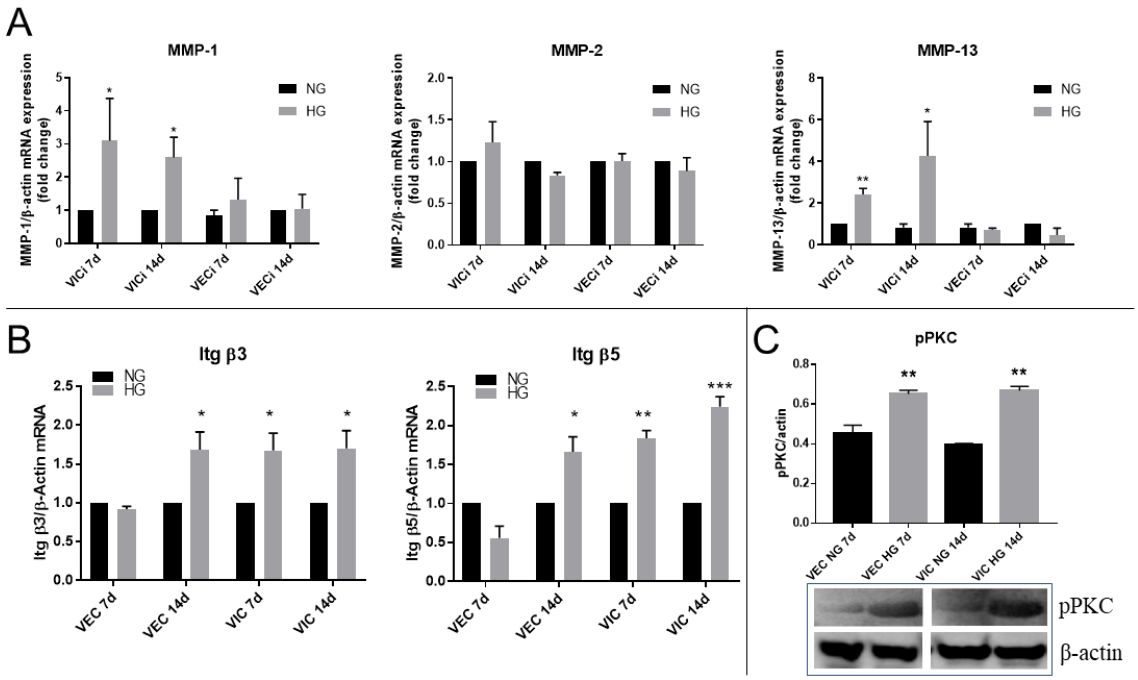

Figura 11 A. *Expresia genică a MMP-1, -2 și -13 în celulele valvulare (VEC și VIC) în modelul 3D expus la concentrații de glucoză normală (NG) sau crescută (HG) timp de 7 și 14 zile.* ***B.*** *Expresia genică a subunităților integrinice β3 și β5 în VEC și VIC din modelul 3D expus la concentrații de glucoză normală (NG) sau crescută (HG) timp de 7 și 14 zile. Celulele au fost izolate din construcții 3D după 7 și 14 zile și investigate prin reacția qPCR.* ***C.*** *Expresia formelor fosforilate ale PKC în VEC și VIC izolate din modelul 3D de valvă aortică. Western blot a fost realizat pe lizatul de celule valvulare izolate din constructul 3D după 7 și 14 zile de expunere la glucoză. În comparație cu NG (coloane negre), celulele din HG (coloane gri) prezintă o expresie crescută a pPKC-α. N = 3, ** p < 0,01.*

Studii anterioare au arătat că PKC reglează expresia MMP-1, în acest capitol, am arătat că forma activă, fosforilată a acesteia este crescută în VIC și VEC din condițiile hiperglicemice (Figura 11C).

Rezultatele din acest capitol contribuie la înțelegerea patologiilor valvulare în condiții de diabet timpuriu și pot deschide căi de cercetare pentru dezvoltarea de terapii țintite pentru prevenirea sau atenuarea progresiei BVA.

Capitolul 4 numit - **Analiza bioinformatică a comunicării dintre celulele valvulare într-un model de șoarece deficient in Apoe** - a avut ca obiectiv principal determinarea unor mediatori ai comunicării intercelulare care pot să inducă modificarea elementelor de MEC observate în celulele interstițiale valvulare, celulele predominante în țesutul valvular, într-un model de șoarece $ApoE^{-/-}$.

Acest capitol abordează metode de analiză bioinformatică a unor date de secvențiere de nouă generație la nivel unicelular (scRNA-seq) obținute și publicate în 2021 (Lee et al., 2022). Acest tip de secvențiere permite observarea heterogenității celulare și totodată permite explorarea interacțiunilor funcționale dintre sub-populațiile celulare din valvă.

Metodele bioinformatice au presupus procesarea și analiza datelor de sc-RNAseq utilizând pachetul informatic Seurat v4 (Hao et al., 2021) în limbajul de programare R. Urmată de o analiză de expresie genică diferențială, pentru sub-populațiile de celule identificate, între populațiile control și cele provenite de la șoareci $ApoE^{-/-}$.

Analiza datelor de scRNA-seq a demonstrat existența a 14 populații de celule valvulare din care 3 sub-populații reprezintă celule valvulare interstițiale (Figura 12).

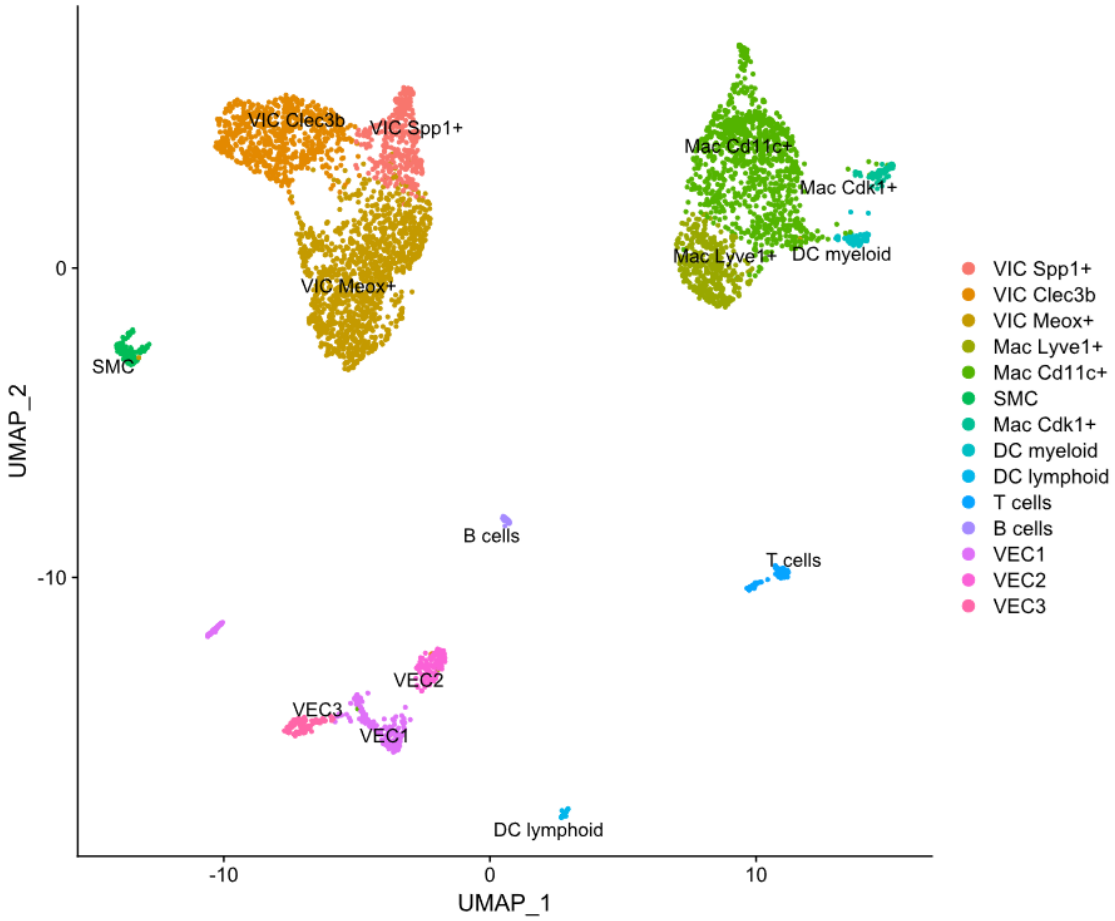

Figura 12 *Proiecția UMAP care surprinde structura datelor de sc-RNAseq și relația dintre cele 14 grupuri de celule valvulare.*

Dintre aceste grupuri de VIC, o sub-populație caracterizată printr-o expresie crescută a osteopontinei, prezintă modificări importante ale genelor de MEC în hiperlipidemie, fiind observată creștrea genelor Col1a1, Col2a1, Col3a1, Fn1, Spp1 și a inhibitorului de MMP – Timp1 (Figura 13A). O analiză de tip GSEA a tuturor genelor modificate semnificativ în acest grup (Figura 13B) a arătat că majoritatea genelor modificate în hiperlipidemie sunt gene prezente în spațiul extracelular și sunt implicate în organizarea fibrelor de colagen sau a matricei extracelulare.

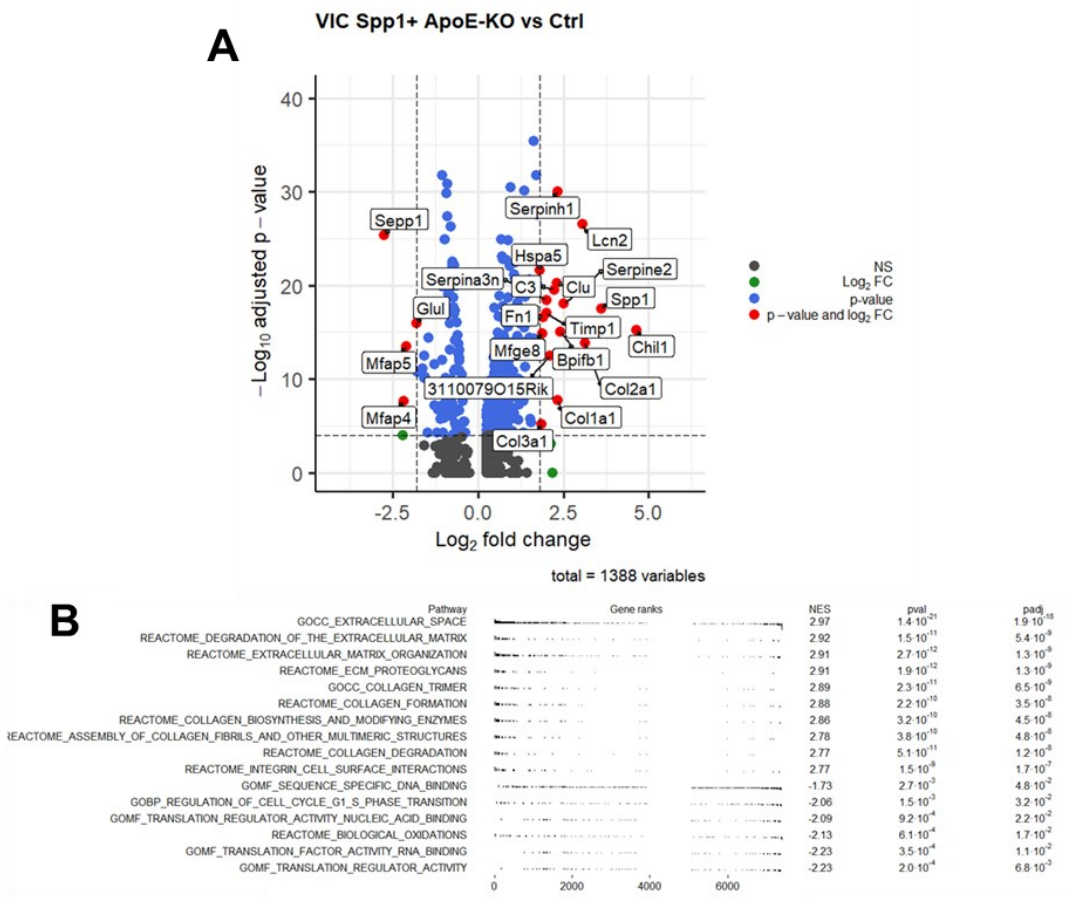

Figura 13 A. *Analiza diferențială a expresiei genelor din VIC Spp1^{+} între condiția Apoe$^{-/-}$ și control. În volcano plot, gri definește genele nemodificate; albastru - genele care trec de pragul valorii p; verde – genele care trec pragul Log2FC dar nu și pe cel al valorii p; iar genele roșii sunt genele semnificativ modificate care îndeplinesc ambele condiții. Pragul de semnificație a fost de p≤10^-5 și Log2FC= 1,8; iar testul statistic folosit a fost Wilcoxon rank sum.* ***B.*** *Cele mai îmbogățite seturi de gene pentru VIC Spp1^{+} modificate semnificativ în condiția Apoe$^{-/-}$, ordonate după scorul normalizat de îmbogățire (NES).*

Pentru a observa ce mediatori ai comunicării intercelulare valvulare pot determina modificările observate în grupul de VIC Spp1^{+} am utilizat o metodă computațională de modelare a comunicării intercelulare utilizând pachetul informatic NicheNet (Browaeys et al., 2020). Acest pachet integrează informațiile experimentale de sc-RNAseq cu baze de date care conțin informații despre interacțiunile ligand-receptor, semnalizare intracelulară și reglarea transcrierii, ceea ce permite evidențierea unor noi mediatori ai semnalizării și a comunicării inter-celulare în procesele patologice.

Această analiză sumarizată în Figura 14 a stabilit o serie de potențiali liganzi cu potențial reglator pentru acest cluster VIC Spp1^{+}.

Figura 14 Sumarizarea analizei de bioinformatică a comunicării intercelulare realizată cu ajutorul pachetului Nichenet. A) Primii 40 de liganzi rezultați în urma analizei de activitate a liganzilor ordonați în funcție de aria de sub curba de precizie-recuperare (AUPR). **B)** Expresia relativă și procentul de celule care exprimă cei 40 de liganzi calculată pentru fiecare grup de celule valvulare. Mărimea punctelor este direct proporțională cu procentul de celule care exprimă respectivul ligand în fiecare grup, iar roșul definește o expresie mai crescută comparativ cu expresia medie a acelui ligand, în timp ce albastru definește o expresie relativă mai scăzută. C) Modificarea expresiei genice a liganzilor în șoarecele $Apoe^{-/-}$. Cu roșu este reprezentată o creștere a expresiei genice în $Apoe^{-/-}$ comparativ cu controlul, iar cu albastru scăderea expresiei genice. D) Genele țintă exprimate în VIC $Spp1^{+}$ și modificate în $Apoe^{-/-}$ pe care fiecare ligand îl poate modifica. Cu mov este calculat un potențial reglator bazat de informațiile ligand-țintă prezente în modelul NicheNet.

Liganzii cu cel mai mare potențial reglator sunt reprezentați de IL-1β, FGF-2, TGF-β1, BMP-4 și CSF2 (Figura 15). Dintre liganzii identificați, TGF- β1 este exprimat în principal de VIC dar și de macrofagele CD11c+, BMP-4 este exprimat în principal de celulele valvulare endoteliale, iar IL-1β este exprimat de celulele dendritice și macrofagele Cd11c+, iar macrofagele proinflamatoare pot comunica și induce modificări în VIC Spp1+ prin secreția de Il1b, Lgals3, Tgf-β1. Dintre acestea atât Lgals3 cât și Il1b prezintă o creștere a expresiei în hiperlipidemie.

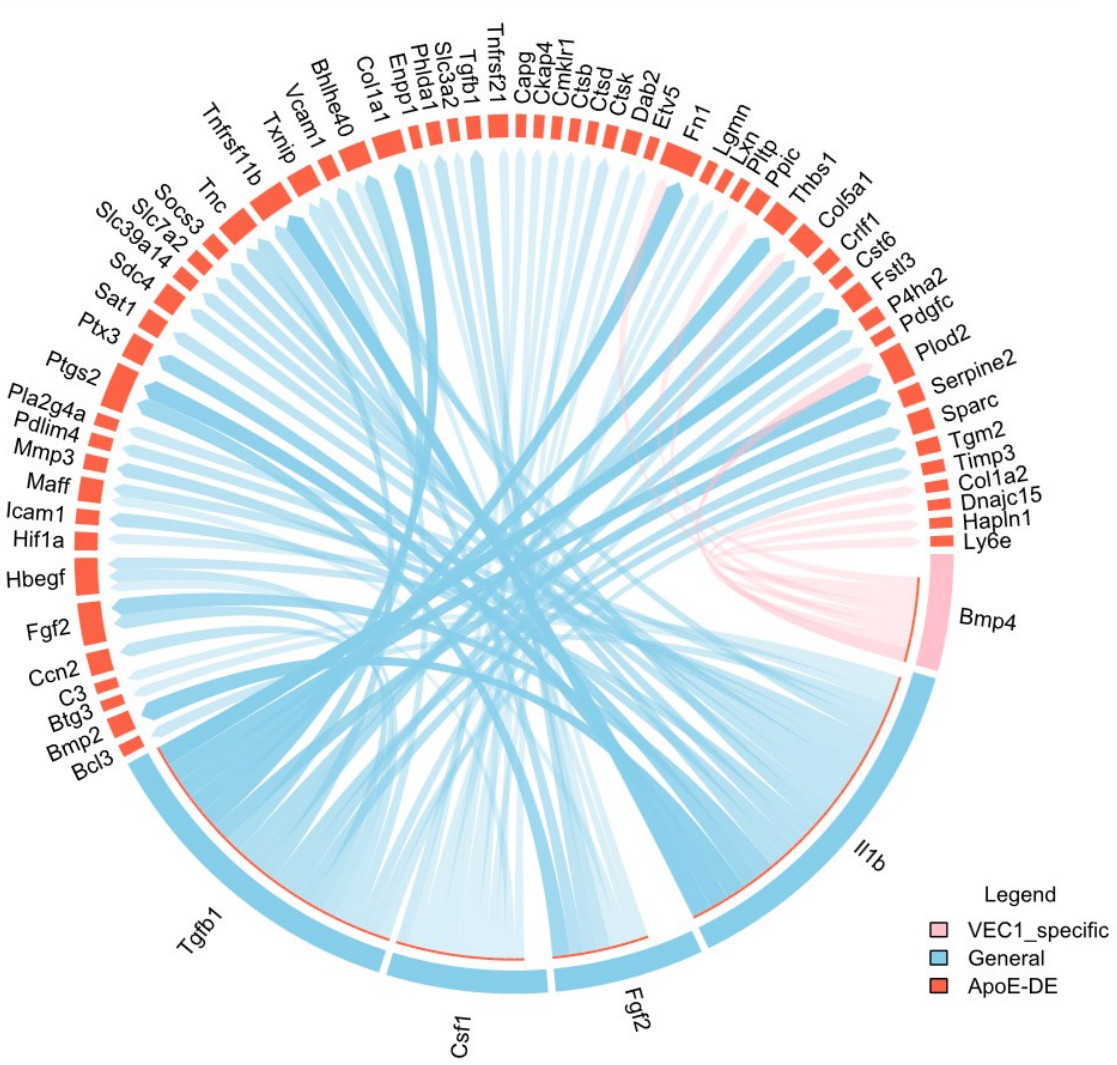

Figura 15 Reprezentarea grafică circulară a liganzilor cu cel mai puternic potențial reglator și genele lor țintă. În partea de jos marcați cu albastru sunt liganzii (Tgfb1, Csf1, Fgf2 și Il1b) care nu sunt exprimați doar de un singur tip celular specific; cu roz este marcat Bmp4 care este exprimat doar în grupul VEC; iar în partea de sus a graficului și marcat cu portocaliu sunt reprezentate genele țintă pentru fiecare ligand.

În concluzie, această lucrare aduce contribuții semnificative pentru înțelegerea modificărilor patologice ale matricei extracelulare, care survin în contextul aterosclerozei și a BVA, utilizând tehnici de cercetare complexe.

În primul capitol am evidențiat noi mecanisme prin care comunicarea dintre celulele musculare netede și macrofage poate influența evoluția ateromului către o placă vulnerabilă prin amplificarea inflamației determinată de creșterea mediatorilor inflamatorii: G-CSF, GM-CSF, ICAM-1, IL-6, CCL5 și MIP-1β. Am arătat și că această inflamație este dependentă de activarea inflamazomului NLRP3 și a căii de semnalizare ERK/MAPK.

În cel de-al doilea capitol am urmărit efectul glucozei crescute în amplificarea remodelării matriceale și am demonstrat că expresia și activitatea enzimelor de remodelare a matricei extracelulare: MMP-3, -8, -1 și -9 este crescută în condiții de glucoză crescută iar aceste modificări sunt modulate de semnalizarea prin prin PKCα și de semnalizarea prin receptorul CCR2.

În cel de-al treilea capitol am identificat modificări ale matricei extracelulare valvulare într-un model de șoarece $Apoe^{-/-}$ diabetic la o perioada scurtă de 4 și 7 zile de la declanșarea diabetului, înainte de fibroza și calcificarea valvei. Utilizând acest model experimental am arătat că expresia fibronectinei și a metaloproteazelor MMP-2 și -9 este crescută la acești șoareco iar aceste modificări se corelează pozitiv cu parametrii plasmatici și funcționali ai valvei. Dorind să investighez modificările induse de diabet la nivel celular, experimentele din capitolul 3 au fost continuate pe un model de studiu *in vitro* tri-dimensional cu VIC la interior și VEC la exterior care a fost menținut în glucoză crescută timp de 7 și 14 zile. Rezultatele obținute pe acest model au arătat că glucoza crescută determină modificări ale expresiei genice de laminină gamma, collagen de tip III, a enzimelor MMP-1 și MMP-13 și a subunităților integrinice β3 și β5 în VIC, iar în VEC crește expresia genică a subunităților integrinice α4, αV și β.

Cel de-al patrulea capitol a presupus o analiză complexă a unor date de secvențiere a ARN la nivel unicelular a valvei aortice provenite de la șoareci C57BL/6J și $Apoe^{-/-}$. Prin această analiză am identificat existența unei sub-populații de VIC care suferă modificări semnificative ale genelor MEC în hiperlipidemie. Modelarea bioinformatică a comunicării intercelulare în valvă a arătat că aceste modificări pot fi mediate de: IL-1β, FGF-2, TGF- β1, BMP-4 și CSF2.

Investigarea modificărilor MEC induse și de efectul diabetului, surprinde un domeniu de studiu în care contribuțiile științifice sunt încă reduse.

Datele prezentului studiu reprezintă un avans important în acest domeniu furnizând perspective noi privind modalitatea prin care remodelarea MEC afectează progresia BVA și a leziunilor aterosclerotice. În plus, aceste date pot ajuta la dezvoltarea de abordări terapeutice noi, centrate pe țintirea comunicării intercelulare și ameliorarea remodelării patologice a MEC.

Importanța studiului

Înțelegerea mecanismelor care conduc la diferențierea celulelor stem este scopul principal al numeroaselor studii. Accesibilitatea ADN-ului pentru factorii de transcripție depinde de structura cromatinei și gradul său de compactare. Analizele recente ale modificărilor epigenetice de la nivelul celulelor stem umane și murine au furnizat noi date despre proprietățile de pluripotență ale celulelor stem și a capacității lor de diferențiere. Aceste mecanisme determină o ierarhie a transcrierii, sunt mediate de factori de transcripție și sunt menite să controleze expresia genelor fără să altereze structura ADN. Capacitatea de multipotența a celulelor stem se reduce în timp, datorită represiei anumitor gene care prezintă o ”semnătură” epigenetică. Genele active la nivelul celulelor stem sunt silențiate gradat pe măsura trecerii lor în celule progenitoare, iar un alt subset de gene țesut-specifice sunt activate. Această progresie este realizată prin expresia selectivă a factorilor de transcripție care recunosc și interacționează cu diferitele modificări epigenetice de la nivelul cromatinei. Ca rezultat al acestor evenimente, cromatina devine accesibilă pentru transcriere la nivelul anumitor regiuni, permițând un control spațial și temporal necesar diferențierii celulelor stem. De exemplu, proteina HP1 (heterochromatine protein 1) își schimbă distribuția, de la o localizare dispersată la nivelul celulelor stem embrionare la o acumulare mult mai concentrată în loci distincți în timpul diferențierii celulare. Acetilarea histonelor era văzută ca un fenomen corelat cu o conformație deschisă a cromatinei, ce permitea exprimarea diferitelor gene implicate în diferențiere. În prezent s-a observat că, în stare acetilată, numeroase gene sunt represate și astfel, diferențierea spre o anumită linie celulară este blocată, menținându-se starea de pluripotență. Manipularea activității histon-deacetilazelor ar putea deveni un instrument util pentru a genera populații de celulele specifice în scopul utilizarii lor în transplant. Descoperirea modelelor de acetilare („*acetylation signature”*) implicate în diferențierea celulelor stem către diferitele tipuri celulare, deschide noi oportunități la interfața dintre chimie și biologia celulei stem, și poate oferi informații valoroase pentru a imbunătăți aplicațiile celulelor stem în ingineria tisulară și medicina regenerativă.

În acest context**, scopul tezei** este investigarea rolului acetilării histonelor în diferențierea celulelor progenitoare endoteliale prin analiza expresiei diferiților markeri genetici și a factorilor de transcripție care reglează activitatea acestor gene. De asemenea, studiile investighează efectul acetilării celulelor progenitoare endoteliale asupra procesului de neovascularizație *in vitro*.

Teza este structurată în două părți principale: partea I – Stadiul actual al cunoștințelor și partea a II-a - Contribuții originale.

Prima parte prezintă stadiul actual al cunoștințelor si este organizată în 3 subcapitole.

Subcapitolul I prezintă noțiuni legate de caracteristicile și proprietățile celulelor stem. În acest subcapitol este prezentat modelul celular utilizat, reprezentat de celulele progenitoare endoteliale și posibilele aplicații clinice ale acestora.

Subcapitolul II face o trecere în revista a principalelor modificări epigenetice. Sunt descrise mecanismele de acțiune a acestor modificări și enzimele implicate în realizarea lor. Tot în acest subcapitol este descris și rolul modificărilor epigenetice în diferențierea celulelor stem către diferite linii celulare.

Subcapitolul III descrie mecanismele acetilării histonelor și rolul lor în diferențierea celulelor stem. În acest subcapitol sunt prezentate principalele clase de histon-acetiltransferaze și histon-deacetilaze, mecanismele de acțiune ale acetilării histonelor, precum și influența acetilării în diferențierea celulelor progenitoare endoteliale.

În Partea a II a - "Contribuții originale", sunt prezentate rezultatele obținute din experimentele care au avut ca scop investigarea rolului acetilării histonelor în diferențierea celulelor progenitoare endoteliale și asupra capacității de neovascularizație *in vitro*.

Capitolul II.2 - “Materiale și Metode“ descrie principalele materiale și tehnici utilizate în experimente, incluzând numeroase tehnici noi de biologie celulara și moleculară: Real-Time PCR, Western-Blot, citometrie în flux, microscopie electronică de transmisie și de baleaj, imunocitochimie și imunohistochimie, metode colorimetrice și fluorimetrice.

Capitolul II.3 - “Rezultate și discuții“ prezintă principalele rezultate originale, obținute în cadrul studiilor efectuate.

Rezultate si discutii

Înțelegerea mecanismelor care conduc la diferențierea celulelor stem este scopul principal al numeroaselor studii. Analizele recente ale modificărilor epigenetice de la nivelul celulelor stem umane și murine au furnizat noi date despre proprietățile de pluripotență ale celulelor stem și a capacității lor de diferențiere. Aceste mecanisme determină o ierarhie a transcrierii, sunt mediate de factori de transcripție și sunt menite să controleze expresia genelor fără să altereze structura ADN-ului. Acetilarea histonelor era văzută ca un fenomen corelat cu o conformație deschisă a cromatinei, care permitea o exprimare a diferitelor gene implicate în diferențiere.

În prezent s-a observat că, în stare acetilată, numeroase gene sunt represate şi astfel diferenţierea spre o anumită linie celulara este blocată, menţinându-se starea de pluripotenţă.

În lucrarea de faţă am demonstrat că sângele din cordon ombilical conţine o populaţie bogată de celule progenitoare endoteliale, având un profil imunofenotipic caracteristic: CD31, CD34, CD133, CD144, CD146, VEGFR2. Analiza moleculară a celulelor obţinute din sânge din cordon ombilical a arătat faptul că sunt exprimate la nivel genic atât gene implicate în morfogeneză cardiovasculară, ca genele pentru factorii de transcripţie GATA2, GATA3, GATA4, cât şi gene caracteristice celulelor endoteliale: CD31, VE-cadherin, VEGFR1, VEGFR2, vWF, CXCR4, Tie-2. Totodată, am arătat că celulele progenitoare endoteliale prezintă o capacitate de proliferare şi migrare superioară în comparaţie cu alte tipuri de celule stem. Aceste celule pot prelua LDL acetilat şi lectina *Ulex europaeus,* pot forma reţele vasculare, fapt ce demonstrează potenţialul lor în angiogeneză şi repararea vasculară. Acest lucru a fost confirmat folosind secţiuni ventriculare embrionare murine viabile sau supuse ischemiei, în care am arătat că celulele progenitoare endoteliale au capacitatea de a se integra şi a forma reţele vasculare. Rezultatele noastre au arătat că celulele progenitoare endoteliale formează structuri vasculare doar la nivelul secţiunilor ventriculare embrionare murine viabile, în timp ce cele ischemice aceste celule doar se integrează, fapt ce demonstrează o comunicare directă intercelulară.

Rezultatele obţinute au arătat că acetiliarea inhibă diferenţierea celulelor progenitoare endoteliale. Inhibitorii deacetilării (VPA, TSA, BuA) menţin cromatina într-o stare acetilată, corespunzătoare unei forme decondensate. Nivelul histon-deacetilazelor a fost semnificativ scăzut în prezenţa acestor inhibitori, iar nivelul histonei H3 acetilate a crescut, aceste modificări fiind corelate cu expresia markerilor implicaţi în diferenţierea celulelor progenitoare endoteliale. Datele de biologie moleculară şi imunofenotipare au arătat că inhibitorii HDAC scad expresia pentru VWF, VEGFR2, eNOS, CD117, CD133, CD144, CXCR4 şi Tie-2, în timp ce expresia CD34 şi CD45 rămâne neschimbată demonstrând că histon-deacetilazele sunt implicate în diferenţierea endotelială. Expresia VE-caderin a fost inhibată semnificativ atât la nivelul ARNm cât şi la nivel proteic. Mecanismul care stă la baza modificării expresiei VE-caderin poate fi explicat prin imposibilitatea factorilor de transcripţie de tipul HoxC6, să interacţioneze cu histonele acetilate pentru a activa promotorul VE-caderin. Expresia genică a CXCR4, Tie-2 şi VEGFR2 a scăzut semnificativ în urma tratamentului cu TSA, mecanismul implicat fiind controlat de factorii de transcripţie Hox a căror expresie este modulată în prezenţa acestor inhibitori. Rezultatele noastre au arătat că, în

stare acetilată, expresia HoxD9 este crescută în celulele progenitoare endoteliale atât la nivel genic cât și proteic.

Procesul de neovascularizație este un poces complex care implică o serie de etape interconectate ducand la formarea de noi vase de sânge atunci când au loc leziuni vasculare în organismele adulte. Spre deosebire de angiogeneză, care reprezintă formarea de vase de sânge din unele pre-existente, neovascularizația are loc prin intermediul celulelor progenitoare endoteliale. Acestea sunt mobilizate să migreze, prolifereze și diferențieze la locul țintă, sub acțiunea citochinelor și a micromediului. Rezultale noastre au arătat că acetilarea inhibă procesul de neovascularizație *in vitro*, acționând la nivelul proceselor de proliferare, aderare, migrare și diferențiere a celulelor progenitoare endoteliale. Celulele progenitoare endoteliale au prezentat un nivel semnificativ scăzut al activității telomerazei în comparație cu controlul, sugerând o scădere a proliferării celulare.

Motilitatea celulară, evaluată folosind metoda " *wound-healing assay*" și prin măsurarea impedanței celulare, a demonstrat faptul că inhibitorii HDAC folosiți scad motilitatea celulară la 24 de ore de la stimulare. În schimb, chemotaxia celulelor progenitoare endoteliale a crescut în urma tratamentului cu inhibitori HDAC, fapt ce poate fi explicat prin menținerea fenotipului circulant al acestor celule progenitoare. În prezența VPA 3mM s-a observat o stimulare semnificativă a chemotaxiei celulelor progenitoare endoteliale către angiopoietina, VEGF și SDF. După proliferarea, mobilizarea, migrarea și aderarea celulelor endoteliale către situsul țintă, ultima etapă constă în organizarea lor în rețele vasculare. Am urmărit și această etapă în condiții de acetilare. Cultivarea pe Matrigel, în prezența de inhibitori HDAC a celulele progenitoare endoteliale, a arătat că acestea nu pot forma rețele vasculare. Pentru a confirma aceste rezultate am folosit și alte matrice pe bază de colagen. Rezultatele au arătat că celulele progenitoare endoteliale izolate din sângele de cordon ombilical au avut capacitatea de a supraviețui și adera la aceste matrice de colagen. Mai mult, aceste celule emit prelungiri, interacționează între ele și cu matricea, formând rețele în aceste structuri. În stare acetilată, celulele progenitoare endoteliale își pierd această capacitate, fapt ce demonstrează că acetilarea inhibă neovascularizația celulelor endoteliale *in vitro*.

Manipularea activității histon-deacetilazelor ar putea deveni un instrument util pentru a genera populații de celulele specifice în scopuri de transplant. Descoperirea modelelor de acetilare („*acetylation signature"*) implicate în diferențierea celulelor stem către diferitele tipurile celulare, deschide noi oportunități la interfața dintre chimie și biologia celulei stem, și poate oferi informații valoroase pentru a imbunătăți aplicațiile celulelor stem în ingineria tisulara și medicina regenerativă.

Reducerea disfuncţiei renale prin modularea farmacologică a mecanismelor epigenetice implicate în acetilarea histonelor în diabetul experimental

Diabetul este o maladie care afectează ~9,3% din populaţia adultă la nivel mondial. Această boală metabolică complexă reprezintă un factor de risc major pentru dezvoltarea anumitor afecţiuni micro- si macrovasculare care scad calitatea vieţii şi cresc riscul evenimentelor cardiovasculare majore. Conform statisticilor, aproximativ 48% din totalul pacientilor diabetici au vârsta mai mică de 70 de ani. Diabetul este clasificat în diabet de tip 1 sau insulino-dependent caracterizat prin producţia insuficientă de insulina, care poate apărea încă din copilărie si diabet de tip 2, sau non-insulino dependent datorat modului ineficient al celulor de a utiliza insulina, acesta reprezintă 95% din cazurile de diabet globale şi apare, în general, la adulţi. Diabetul gestational, poate aparea în timpul sarcinii şi este caracterizat prin valori hiperglicemice, peste normal dar sub valorile patologiei diagnosticabile. Una dintre complicaţiile cronice ale diabetului este **nefropatia diabetica**, care se caracterizează prin alterarea funcţiei renale, conducând, în fazele avansate ale bolii la dializă sau transplant renal. Pacienţii cu nefropatie diabetică au un risc crescut de a dezvolta boli cardiovasculare şi un risc major de deces. [1]

Principalele caracteristici ale **nefropatiei diabetice** sunt micro-/macro-albuminuria, proteinuria, îngroşarea membranei bazale glomerulare, hipertrofia podocitelor, hiperplazia şi hipertrofia celulelor mezangiale, infiltrarea celulelor sistemului imunitar şi creşterea nivelului de specii reactive de oxigen. Răspunsul inflamator este menţinut la un nivel crescut prin activarea unor factori de transcriere pro-inflamatori, cum ar fi factorul nuclear kappa β (NF-kB), factorul de transcripţie AP-1, C/EBP, şi STAT1 care determină creşterea stresului oxidativ [2].

Modificările epigenetice determină creşterea expresiei de molecule care au un rol important în patofiziologia complicaţiilor vasculare asociate diabetului zaharat, cum ar fi complexul NADPH oxidaza, mediatori pro-inflamatori (citokine, chemokine) şi pro-fibrotici (elemente

de matrice extracelulara, factori de creştere), agenţi vasoactivi (endotelina-1), metaloproteinaza matriceală 9, moleculele de adeziune celulară vasculară (VCAM-1), molecule intracelulare de adeziune-1 (ICAM-1), E-selectina (E-sel). Aşadar, este foarte important să fie investigate noi mecanisme moleculare pentru a avea la dispoziţie alte abordari terapeutice în tratarea nefropatiei diabetice.

În această lucrare au fost investigate rolurile mecanismelor epigenetice implicate în acetilarea histonelor nucleozomale în instalarea stresului oxidativ, a inflamaţiei şi a fibrozei renale în diabetul experimental în vederea dezvoltării de noi terapii pentru tratamentul bolii renale diabetice.

Ipoteza acestei lucrări constă în faptul că hiperglicemia induce dezechilibrul mecanismelor epigenetice dependente de acetilarea histonelor, o condiţie patologică care determină o creştere a nivelurilor de exprimare specifice unor sisteme enzimatice implicate în producţia de specii reactive de oxigen şi a unor mediatori pro-inflamatori şi pro-fibrotici la nivel renal.

Obiectivele acestei teze au fost:

Obiectivul 1. Investigarea rolului căilor de semnalizare dependente de histon acetiltransferaza p300/CBP în instalarea stresului oxidativ, inflamaţiei şi fibrozei renale în diabetul experimental.

Obiectiv 2. Dezvoltarea unei strategii farmacologice inovatoare bazată pe triterpene pentru reducerea disfuncţiei renale în diabetul experimental.

Obiectivul 3. Dezvoltarea unei metode de detecţie a speciilor reactive de oxigen în ateroscleroza experimentală prin imagistică moleculară de înaltă rezoluţie în domeniul spectral infraroşu apropiat utilizând lipozomi funcţionalizaţi

Prima parte a tezei, intitulată stadiul actual al cunoaşterii bolilor rinichiului diabetic, oferă informaţii cu privire la mecanismele patologice care stau la baza instalării bolii renale diabetice sau nefropatiei diabetice.

În capitolul II, sunt prezentate contribuţiile ştiinţifice originale care vizează implicarea histon-acetiltransferazei p300/CBP în patologia nefropatiei diabetice punându-se un

accent deosebit pe sistemul enzimatic ce produce NADPH oxidaze (surse vasculare generatoare de specii reactive de oxigen şi stres oxidativ) şi pe moleculele pro-inflamatoarii şi pro-fibrotice. De asemenea au fost investigate potenţialele efecte terapeutice ale acidului ursolic şi a unui complex bioactiv standardizat format din Acid ursolic (90.7%) şi Acid oleanolic (5.8%) în modularea unor procese patofiziologice asociate disfuncţiei renale în diabetul experimental. Producţia crescută de specii reactive de oxigen şi creşterea stresului oxidativ reprezintă o caracteristică a bolilor cardiovasculare. În acest context, au fost realizate studii care stau la baza dezvoltării unei metode inovatoare pentru derminarea producţiei de specii reactive de oxigen *in vivo* pe modele animale cu ateroscleroză utilizând lipozomi functionalizaţi pentru încapsularea unui compus redox sensibil, ROS Brite™ 700, care prin oxidarea sa emite un semnal fluorescent specific în domeniul spectral infraroşu apropiat.

Concluzii

- **I.Analiza rolului căilor de semnalizare dependente de histon acetiltransferaza p300/CBP în instalarea stresului oxidativ, a inflamaţiei şi a fibrozei renale a şoarecilor diabetici în diabetul experimental.**

  În concluzie, în rinichii diabetici, activarea histon acetiltransferazei p300 / CBP duce la creşterea producţiei de ROS (cel mai probabil generate de proteinele Nox), a inflamaţiei şi a producţiei de proteine ale matricei extracelulare. Pe baza faptului că p300 / CBP este un important activator co-transcripţional care reglează expresia unei game largi de gene pro-oxidante, pro-inflamatorii şi pro-fibrotice, putem afirma că modularea farmacologică a p300 / CBP ar putea deveni o tentantă opţiune terapeutică în nefropatia diabetică.

- **II.Conceperea unei strategii farmacologice inovatoare bazată pe triterpene pentru reducerea disfunctiei renale in diabetul experimental.**

  Probele de extract de *Salvia officinalis* obţinute au un conţinut ridicat de acizi triterpenici, majoritar acid ursolic.

  La concentraţii de 1-10 μM, acizii triterpenici, anume ursolic, oleanolic, betulinic şi complexul bioactiv standardizat format din acizii triterpenici AU

(90.7%) şi AO (5.8%) determină reducerea nivelelor de exprimare ARNm specifice unor molecule pro-oxidante şi pro-inflamatorii cu rol important în patofiziologia complicațiilor cardiovasculare asociate diabetului zaharat.

Tratamentul şoarecilor diabetici cu acid ursolic sau complexul bioactiv standardizat format din AU (90.7%) şi AO (5.8%) a determinat scăderi semnificative ale hipertrofiei glomerulare şi a nivelelor de exprimare genică sau proteică specifice unor molecule (de stres oxidativ, inflamaţie şi fibroză) cu rol important în patofiziologia nefropatiei diabetice.

Acidul ursolic (UA) determină reducerea nivelelor de exprimare genică specifice unor molecule asociate fenotipului pro-inflamator (M1) al macrofagelor în cultură.

- **III.Detectarea speciilor reactive de oxigen vasculare produse *in vivo* în ateroscleroza experimentală prin imagistică cu spectrul de emisie în domeniul infraroşu apropiat de înaltă rezoluţie utilizând lipozomi funcţionalizaţi.**

  Datele obţinute indică faptul că încapsularea RB700 în Lp stabilizaţi steric ce ţintesc endoteliul ar putea deveni o metodă fiabilă pentru a cuantifica şi vizualiza direct locurile de formare a ROS în sistemul vascular şi organe la modelele animale . Această metodă ar putea fi aplicată nu numai în ateroscleroza experimentală, ci şi pentru cancer, diabet, obezitate şi boli neurodegenerative, deoarece toate aceste boli sunt caracterizate de formarea crescută a ROS. Mai mult, această nouă configuraţie pentru detectarea moleculară a ROS bazată pe RB700-Lp ce vizează endoteliul activat este de o importanţă deosebită pentru a sublinia intensitatea şi mecanismul (mecanismele) de producere a stresului oxidativ indus de factorii de risc asociat cu diferite patologii, precum şi ceea ce priveşte dezvoltarea şi testarea preclinică a noi medicamente şi strategii terapeutice.

Rezultatele originale obținute în cadrul acestei teze demonstrează că:

1. Activarea căilor de semnalizare legate de histon acetiltransferaza p300/CBP mediază hipertrofia glomerulară şi acumularea proteinelor matricei extracelulare în rinichii şoarecilor diabetici.
2. Inhibarea farmacologică a histonei acetiltransferazei p300/CBP reduce nivelul de acetilare al histonei 3 la restul de lizină 27 (H3K27ac) în rinichii şoarecilor diabetici comparativ cu animalele diabetice.
3. Histon acetiltransferaza p300/CBP mediază creşterea nivelurilor de exprimare genică şi proteică specifice subunităţilor Nox1, Nox2 şi Nox4 în rinichii şoarecilor diabetici.
4. Inhibarea farmacologică a histon acetiltransferazei p300/CBP reduce formarea de specii reactive de oxigen în rinichii şoarecilor diabetici.
5. Tratamentul şoarecilor diabetici cu C646, un inhibitor specific al p300/CBP, reduce semnificativ nivelurile proteice specifice subtipurilor Nox1 şi Nox4 la nivel glomerular.
6. Inhibarea farmacologică a coactivatorului p300/CBP reduce semnificativ activitatea factorilor de transcriere NF-kB şi STAT.
7. Activarea histon acetiltransferazei p300/CBP mediază creşterea nivelurilor genice ale unor mediatori pro-inflamatori (MCP-1, TNFα, NOS2, ICAM-1, VCAM-1, E-selectină) şi pro-fibrotici (colagen IV, fibronectina, laminina).
8. Tratamentul şoarecilor diabetici cu acid ursolic sau cu complexul bioactiv standardizat format din acid ursolic (90.7%) şi acid oleanolic (5.8%) determină scăderi semnificative ale hipertrofiei glomerulare şi a nivelurilor de exprimare genică/proteică specifice unor molecule asociate stresului oxidativ, inflamaţiei şi fibrozei cu rol important în patofiziologia nefropatiei diabetice.
9. Acidul ursolic reduce nivelurile genice specifice subunităţilor catalitice Nox1, Nox2, Nox4 şi Nox5 şi a mediatorilor pro-inflamatori MCP-1, TNFα şi NOS2 în Mac cu fenotip pro-inflamator (M1-Mac) şi a moleculelor de adeziune ICAM-1, VCAM-1 şi E-selectina.
10. Tratamentul şoarecilor diabetici cu acid ursolic sau cu complexul bioactiv standardizat obţinut din frunze de *Salvia officinalis* ce conţine acid ursolic (90.7%) şi acid oleanolic (5.8%) determină o scădere semnificativă a expresiei

proteice a Nox1, Nox2 si Nox4, şi a producţiei de specii reactive de oxigen la nivel glomerular, precum şi formării produşilor precum 4-HNE şi a expresiei de VCAM-1 la nivel glomerular în rinichii şoarecilor diabetici.

11. Lipozomii stabilizaţi steric şi direcţionaţi către molecula de adeziune pro-inflamatoare VCAM-1 reprezintă un sistem de transport eficient de concentrare a indicatorului redox RB700 la nivelul leziunilor aterosclerotice la şoareci ApoE-/-.

REZUMAT

Introducere – stadiul actual al cunoştinţelor

Miopatiile ischemice şi non-ischemice duc la disfuncţia ventriculului stâng şi în final la insuficienţă cardiacă. Aceasta din urmă scade calitatea vieţii, speranţa de viaţă şi creşte costurile medicale, constituind astfel una din problemele majore de sănătate (McMurray şi Pfeffer, 2005). Terapiile actuale asigură într-o oarecare măsură supravieţuirea şi îmbunătăţirea simptomelor, dar nu poate reversa condiţia ţesutului cardiac de la o stare bolnavă la una sănătoasă (Kuraitis *et al.*, 2011). Dezvoltarea recentă a domeniului celulelor stem ar putea oferi o cale de trata insuficienţa cardiacă prin înlocuirea ţesutului lezat cu ţesut sănătos, fapt ce ar duce la sporirea calităţii vieţii şi supravieţuirea pacienţilor cu diverse cardiomiopatii.

Celulele stem mezenchimale (MSC) din măduva osoasă au fost intens studiate pentru proprietăţile lor regenerative şi imunomodulatoare. Studiile pe modele animale au arătat că tratamentul cu MSC îmbunătăţeşte funcţia cardiacă în urma infarctului miocardic prin scăderea apoptozei şi producerea de factori angiogeni (Tang *et al.*, 2005). Deoarece capacitatea de diferenţiere a MSC în CMC este foarte scăzută şi nu poate explica efectul benefic tranzitoriu al transplantului acestora la locul infarctului observat în studiile preclinice sau clinice (Rose *et al.*, 2008), acest efect a fost pus pe seama efectului paracrin al acestor celule (Gnecchi *et al.*, 2008). Acestea sunt capabile să elibereze factori solubili (citokine, chemokine, factori de creştere) care să acţioneze într-o manieră paracrină asupra celulelor miocardului lezat. Mai mult decât atât, recent a fost demonstrat că MSC sunt capabile să comunice cu celulele învecinate prin intermediul unor fragmente membranare circulare, numite microvezicule. Astfel, MSC pot secreta diverse componente solubile, precum receptori, factori de creştere, lipide biologic active, dar şi acizi nucleici (ARN mesager şi microARN) protejate de acţiunea agresivă a mediului extracelulular (Morel *et al.*, 2004; Gatti *et al.*, 2011).

MSC prezintă o serie de avantaje pentru utilizarea lor în medicină regenerativă, precum: (i) aceste celule pot fi izolate cu uşurinţă şi propagate în cultură pentru a obţine un număr mare de celule, adecvat pentru terapia celulară, (ii) au imunogenicitate scăzută, ceea ce le face potrivite şi pentru transplantul alogen (Dai *et al.*, 2005) şi datorită acestui fapt sunt evitate problemele de etică adiacente altor tipuri de celule stem utilizate pentru transplant, precum celulele stem embrionare (iii).

În acest context, scopul acestei teze a fost studierea unor aspecte privind atât apoptoza CMC în condiții ischemice, precum şi diferențierea MSC obținute din măduva osoasă adultă de şoarece către celule musculare cardiace. Astfel, pe parcursul intregii perioade de doctorat, studiile realizate au fost focalizate pe înțelegerea mecanismelor prin care miocardul este lezat in timpul si consecutiv infarctului miocardic si pe gasirea unei metode eficiente de reparare a acestui tesut. Teza de față este structurata în două părți principale: prima parte prezintă stadiul actual al cunoştințelor legate de subiectul lucrării de doctorat, prezentat pe parcursul a patru capitole, iar cea de-a doua parte prezintă contribuțiile originale ale doctorandului la cunoaşterea ştiințifică, organizate de asemenea în patru capitole.

I. **Alterări moleculare care duc la apoptoza cardiomiocitelor în ischemie-reperfuzie**

Capitolul I a căutat să răspundă la întrebarea dacă ischemia sau reperfuzia este responsabilă de inducerea apoptozei în CMC. Cunoaşterea principalului stimul răspunzător de inducerea a procesului apoptotic în CMC este necesar pentru găsirea unei terapii de încetinire a progresiei insuficientei cardiace datorate pierderii miocardului contractil. Scopul acestui prim studiu a fost determinarea contribuției individuale a ischemiei, reperfuziei şi oxidanților exogeni la inducerea apoptozei în CMC, stabilind astfel contribuția majoră la progresia insuficientei cardiace în ischemia/reperfuzia miocardului.

Astfel, prima parte contribuțiilor originale s-a focalizat pe identificarea principalului stimul răspunzător de inițierea apoptozei în miocard, informație extrem de importantă pentru dezvoltarea unei terapii pentru progresia insuficienței cardiace datorate pierderii miocardului contractil. Rezultatele obținute în această primă etapă a stagiului de doctorat au arătat că principalul inductor al apoptozei în ischemie/reperfuzie a fost reperfuzia, mai degrabă decât ischemia *per se*. Studiul respectiv a demonstrat că oxidanții exogeni aduşi din mediul înconjurător în timpul reperfuziei sunt principalii determinanți ai apoptozei CMC. 25-hidroxicolesterolul, un component al LDL oxidat, promovează apoptoza CMC printr-un mecanism dependent de caspaza-3, care presupune creşterea expresiei proteinei pro-apoptotice Bax (figura 1), reglată la nivel transcripțional, concomitent cu degradarea post-translaționala a proteinei-anti-apoptotice Bcl-2 (figura 2). Alterarea raportului proteinelor pro- şi anti-apoptotice creează condiții favorabile inițierii procesului apoptotic, care se poate desfăşura doar în timpul reperfuziei, când rezervele de ATP şi glucoză sunt refăcute. Datele obținute în urma acestui studiu indică faptul că terapia cu antioxidanți, ar putea juca un rol important pentru salvarea

miocardului viabil în urma unui infarct prin prevenirea pierderii CMC prin moarte celulară programată.

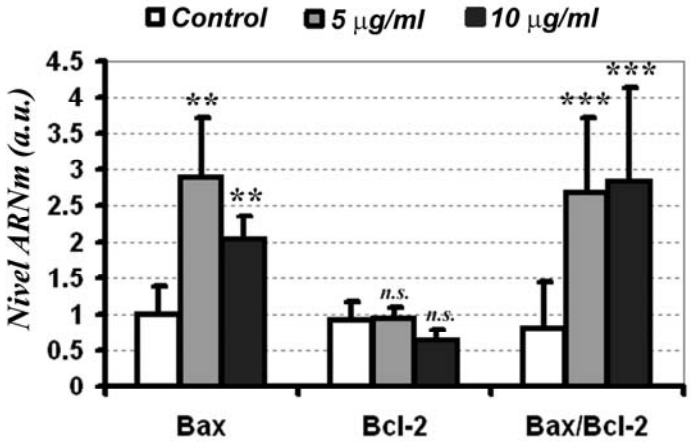

Figura 1: Modificări induse de tratamentul cu 25-HC în expresia genică a proteinelor pro- şi anti-apoptotice Bax şi Bcl-2 în CMC după 72 de ore de tratament cu 25-HC.

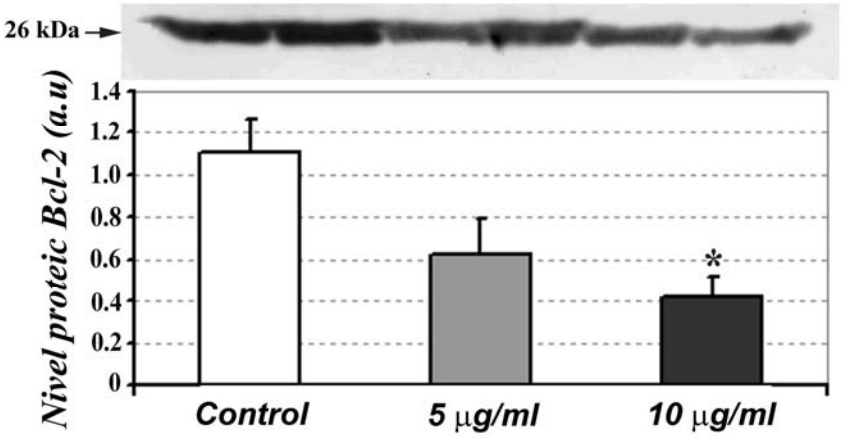

Figura 2: Cuantificarea prin Western Blot a nivelului expresiei proteice a Bcl-2 după tratamentul CMC cu 25-HC.

II. Izolarea celulelor stem mezenchimale

Următoarea etapă a stagiului a presupus punerea la punct a unor metode de obținere a MSC din măduva osoasă de şoarece adult, în vederea utilizării acestora în studii de diferențiere în CMC. Această etapă a studiilor de doctorat a prezentat un interes special deoarece, aşa cum este cunoscut în literatură, MSC de şoarece sunt mult mai dificil de izolat şi de propagat *in vitro* decât celulele umane sau de şobolan, din cauza contaminării cu celule de origine hematopoietică. Din

această cauză, obținerea unei culturi de MSC de şoarece a reprezentat o provocare care s-a concretizat în izolarea acestui tip de celule concomitent prin două metode. Cultura pură de MSC obținută a fost ulterior caracterizată conform sugestiilor Societății Internaționale de Transplant Celular.

II.1. **Izolarea celulelor stem pe gradient de Percoll**

Rezultatele obținute au arătat că centrifugarea aspiratului medular de şoarece pe un gradient discontinuu de Percoll determină separarea celulelor în şase fracții, corespunzător densităților 1.050, 1.057, 1.067, 1.070, 1.076 şi 1.083 g/ml (figura 3). Celulele progenitoare, caracterizate de expresia markerilor Sca-1 şi c-kit, s-au regăsit în fracțiile III-V.

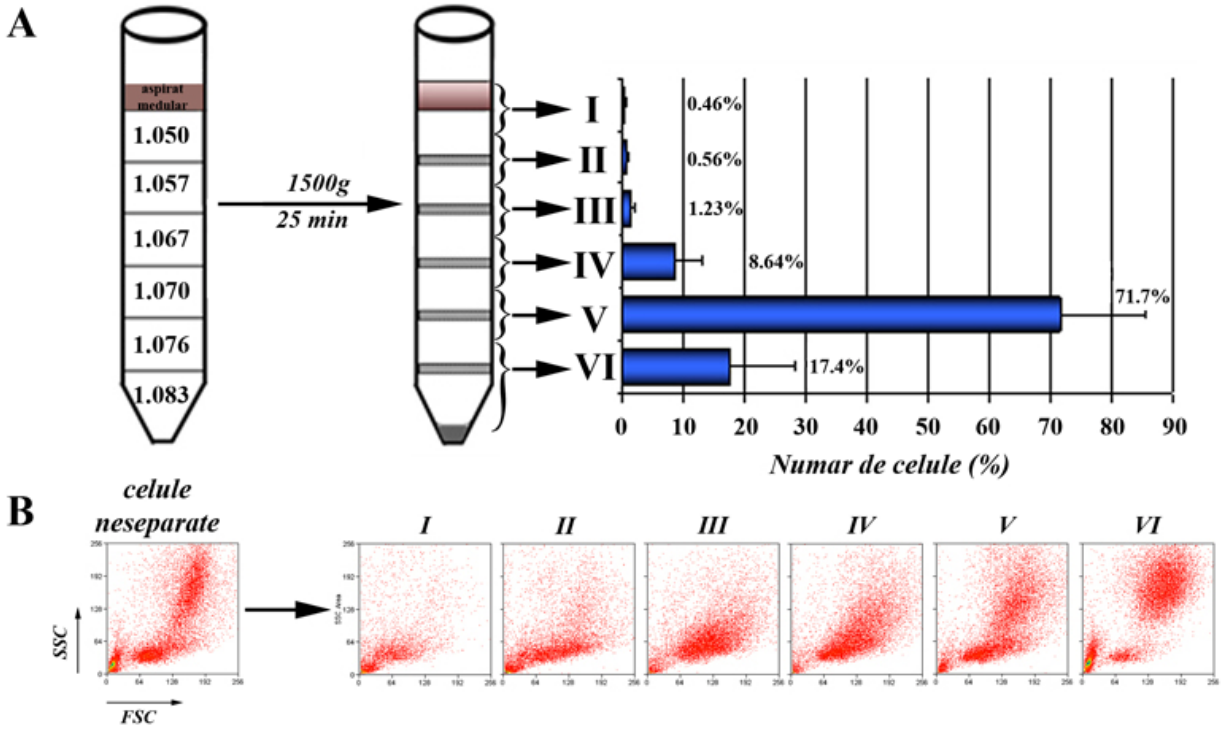

Figura 3: Separarea celulelor din măduva osoasă în şase fracții prin centrifugare pe gradient discontinuu de Percoll. (A) Ilustrare schematică a gradientului de Percoll discontinuu folosit pentru fracționare şi procentele corespunzătoare celulelor recuperate din fiecare fracție după centrifugare. (B) Histograme de citometrie de flux ilustrând heterogenitatea celulelor înainte de separare şi morfologia celulelor în fiecare fracție.

Fracția IV a fost considerată ca fiind de interes, deoarece la nivelul acesteia au segregat aproximativ $2x10^6$ celule progenitoare dintr-un total de $4.3x10^6$ celule (figura 4). Deşi compoziția

celulară a acestei fracții a fost heterogenă, aceasta a cuprins, pe lângă celule c-kit şi Sca-1 pozitive, şi celule endoteliale, care ar putea juca un rol important în refacerea miocardului lezat după infarct, prin contribuția la revascularizarea țesutului prin angiogeneză. Prin cultivare, aceasta fracție a generat o cultură $CD45^{-}$/$c\text{-}kit^{-}$/$Sca\text{-}1^{+}$/$PECAM^{-}$/$VEGFR2^{-}$/osteocalcină$^{-}$/colagen II^{-}, care, prin incubare în condiții specifice de diferențiere, a generat adipocite şi osteoblaste, demonstrând caracterul multipotent al acestor celule (figurile 5 si 6).

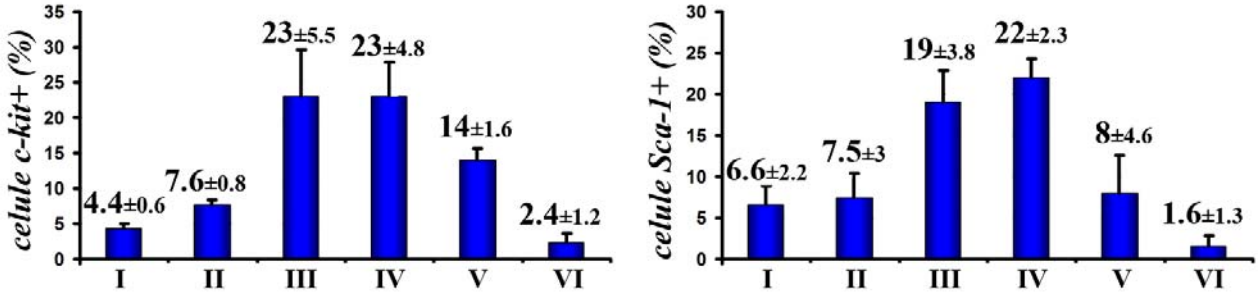

Figura 4: Reprezentarea grafică a mediei procentelor de celule c-kit^{+}, respectiv Sca-1^{+} din fiecare fracție din trei experimente diferite.

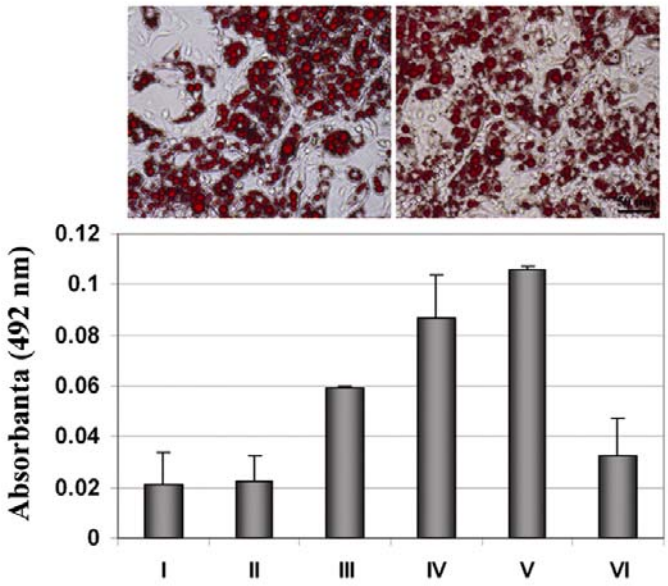

Figura 5: Cuantificarea spectrofotometrică a acumulării de lipide în cele şase fracții după cultivarea celulelor în mediu adipogenic. În partea superioară se găsesc imagini reprezentative ale fracțiilor III şi IV colorate cu Oil Red. Fracția V, deşi prezintă acumulare masivă de lipide, nu este îmbogățită în celule progenitoare, colorația datorându-se probabil prezenței preadipocitelor la acest nivel.

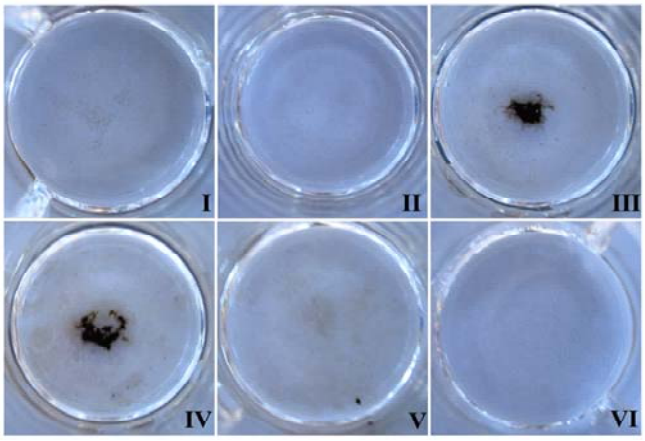

Figura 6: Imagine de microscopie optică reprezentând coloraţia von Kossa a celulelor aderente obţinute din cele şase fracţii după două săptămâni de cultivare în mediu osteogenic. Se observă că fracţiile III şi IV, dar nu şi fracţia V (care conţine majoritatea celulelor) au fost capabile să genereze osteoblaste în condiţii de cultură specifice.

II.2. **Izolarea celulelor stem mezenchimale din maduva osoasa hematogena**

In paralel cu metoda prezentata anterior, a fost obtinuta o populatie de celule stem mezenchimale prin mentinerea in cultura aspiratului medular pentru o perioada mai lunga, de aproximativ opt saptamani. Celulele obtinute au format o cultura omogena, cu aspect fibroblast-like si potențial mare de proliferare, fiind uşor de expandat *in vitro*. Caracterizarea acestei culturi prin RT-PCR (figura 7a) a arătat expresia markerilor de celule stem Sca-1 şi CD105 (endoglina), dar şi lipsa markerului c-kit, ceea ce a indicat sărăcirea în celule progenitoare hematopoietice. O altă caracteristică a acestor celule a constituit-o prezența filamentelor intermediare de vimentină si nestină. Expresia acestor proteine (figura 7b) a sugerat un posibil rol în procesul de regenerare tisulară deoarece prezența filamentelor de nestină este specifică celulelor tinere, cu capacitate de migrare.

Caracterizarea acestor celule a fost completată cu studii de diferențiere către multiple tipuri celulare, precum adipocite, osteoblaste, condrocite şi a demonstrat caracterul multipotent al acestora, menținut nealterat pe parcursul mai multor pasaje (figura 8). Această cultură a fost utilizată în studiile ulterioare de diferențiere către un fenotip muscular, ale caror rezultate sunt cuprinse in Capitolul III al tezei.

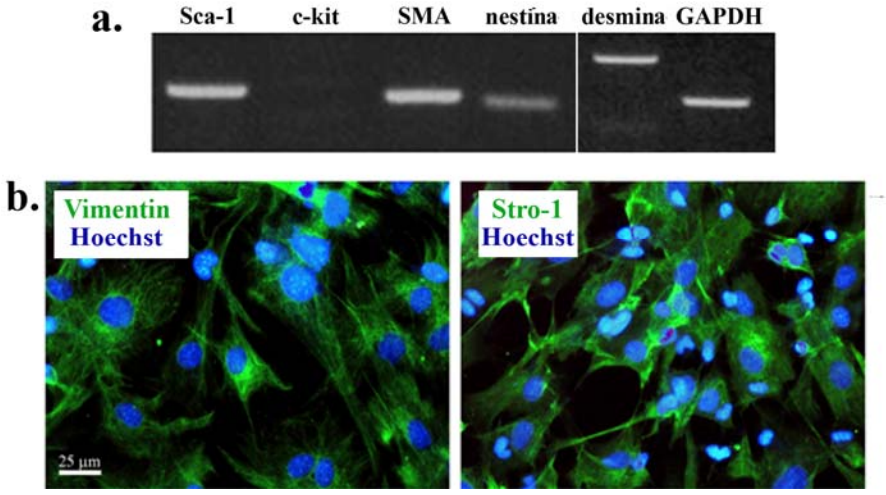

Figura 7: ***(a)*** *RT-PCR arătând expresia la nivel de ARNm a markerilor de MSC: Sca-1, actina specifică celulelor musculare netede (SMA) şi desmina şi lipsa expresiei markerului de celule stem hematopoietice c-kit;* ***(b)*** *Imagine de imunocitochimie arătând prezenta filamentelor intermediare de vimentină şi a markerului de celule stromale Stro-1 la nivelul tuturor celulelor din cultură.*

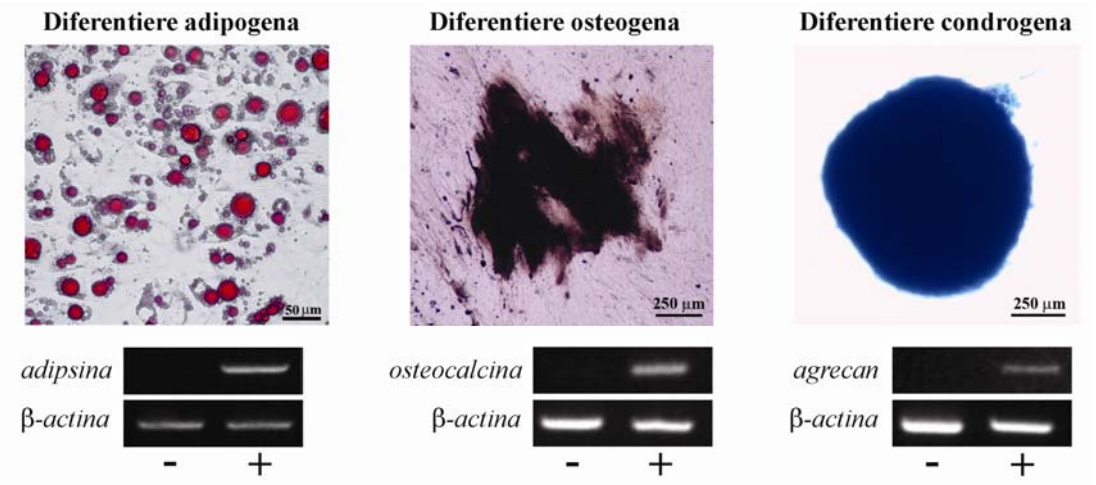

Figura 8: Caracterizarea proprietății de multipotență a MSC. În partea stângă a imaginii este evidențiată diferențierea celulelor către adipocite prin colorarea acumulărilor intracitoplasmatice de lipide cu Oil Red O şi prin determinarea expresiei genice de adipsină prin RT-PCR. În partea centrală se observă diferențierea celulelor către osteoblaste. Sus este prezentat un nodul de calcefiere colorat prin tehnica von Kossa, iar jos este prezentată inducerea expresiei de osteocalcină (RT-PCR). În partea dreaptă este evidențiată sinteza de mucopolizaharide acide a celulelor diferențiate în condrocite prin colorație cu Alcian Blue, precum şi expresia proteoglicanului agrecan în celulele diferențiate.

III. Studii de diferențiere a celulelor stem mezenchimale în cardiomiocite

Pentru inducerea diferențierii MSC către un fenotip cardiac a fost utilizată 5-azacitidina, un compus cu acțiune de demetilare a materialului genetic, cunoscut pentru capacitatea sa de a potența diferențierea celulelor stem embrionare către CMC.

Un punct de interes l-a constituit de asemenea acțiunea 5-azacitidinei asupra multipotenței celulelor stem, respectiv a capacității acestui compus de a afecta capacitatea MSC de a se diferenția către multiple linii celulare. Rezultatele au arătat că celulele tratate cu 5-azacitidina şi-au pierdut progresiv capacitatea de a se diferenția către adipocite şi osteoblaste când au fost incubate în condiții de diferențiere specifice. Un rezultat neaşteptat l-a constituit creşterea potențialului de diferențiere condrogenică consecutiv tratamentului cu 5-azacitidina. Concluzia acestui studiu a fost că MSC îşi păstrează proprietatea de multipotență după prima expunere la acțiunea 5-azacitidinei, dar aceasta este redusă progresiv cu fiecare expunere, concomitent cu creşterea capacității celulelor tratate de a genera condrocite (figura 9).

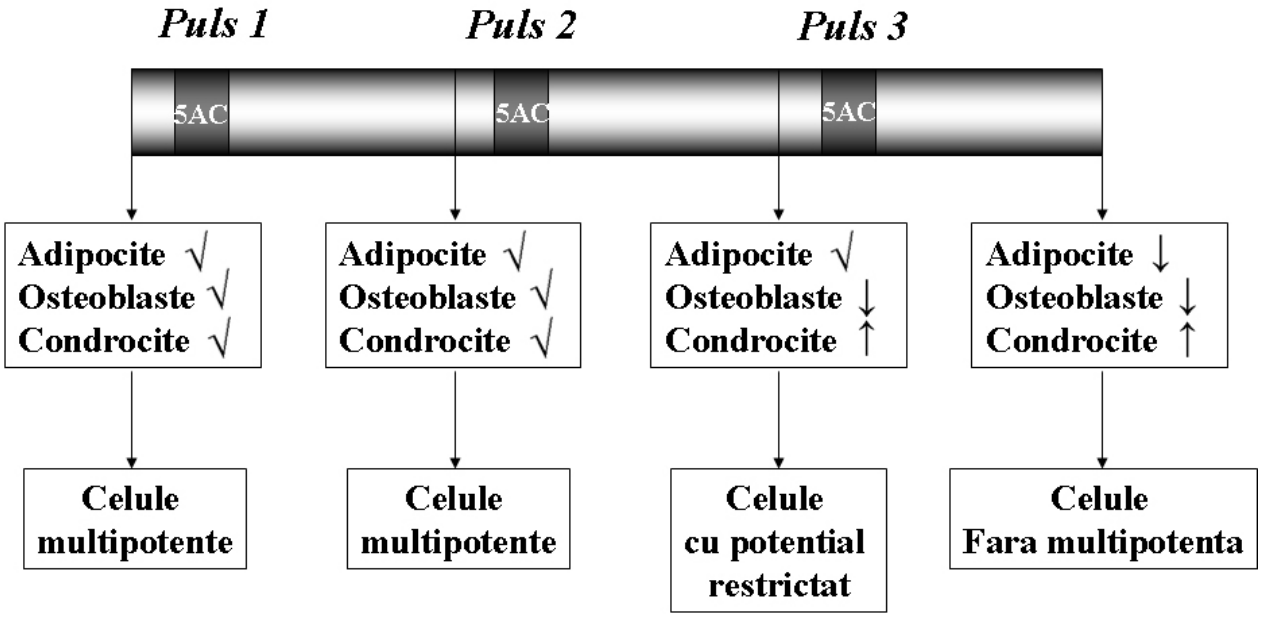

Figura 9: Efectul tratamentului cu 5-azacitidina asupra multipotenței MSC. Aceasta proprietate a devenit restrictată după mai mult de o expunere la 5-azacitidină. După 2 sau 3 pulsuri cu 5-azacitidină, capacitatea MSC de a se diferenția către condrocite a crescut considerabil.

În paralel cu punerea în evidență a modificării caracterului pluripotent al MSC prin tratamentul cu 5-azacitidina, a fost urmărită capacitatea acestui agent demetilant de a induce

diferențierea acestor celule către un fenotip muscular cardiac. Dupa cum se observa in figurile 10 si 11, cu exceptia unor gene specific musculare (α-actina cardiacă, canalul de calciu de tip L), nu a fost indusă expresia nici uneia dintre genele implicate în diferențierea musculaturii cardiace în celulele tratate. Cu toate acestea, 5-azacitidina a indus expresia unor gene specifice musculaturii striate, ceea ce permis diferențierea MSC în mioblaşti în condiții miogene specifice (figura 12). În concluzie, tratamentul MSC cu 5-azacitidină ar putea favoriza diferențierea acestora în celule cardiace, cu condiția determinării unor factori specifici care ar putea influența finalizarea procesului de diferențiere către CMC mature şi funcționale.

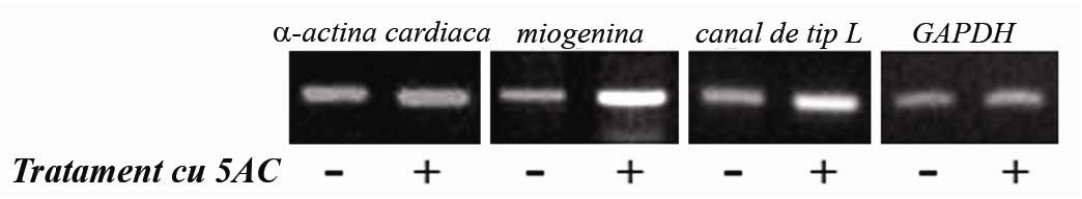

Figura 10: Imagine de RT-PCR arătând expresia crescută a unor gene specific musculare după tratamentul cu 5-azacitidină.

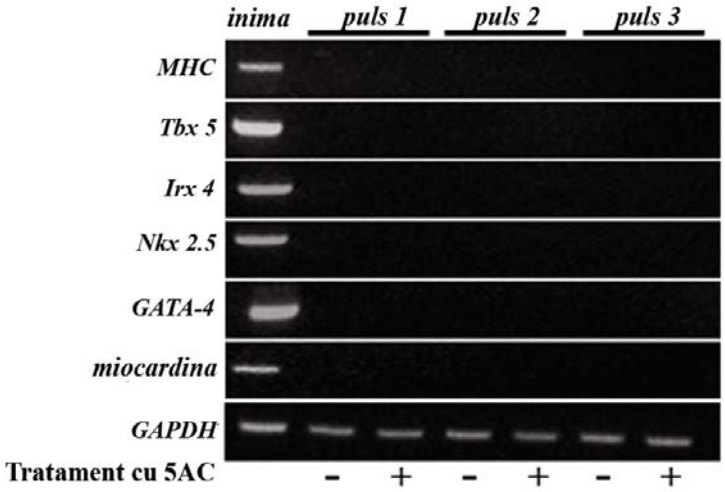

Figura 11: Imagine de RT PCR în care se observă absența inducerii expresiei factorilor de transcripție, precum şi a altor gene specific cardiace după tratamentul cu 5-azacitidină.

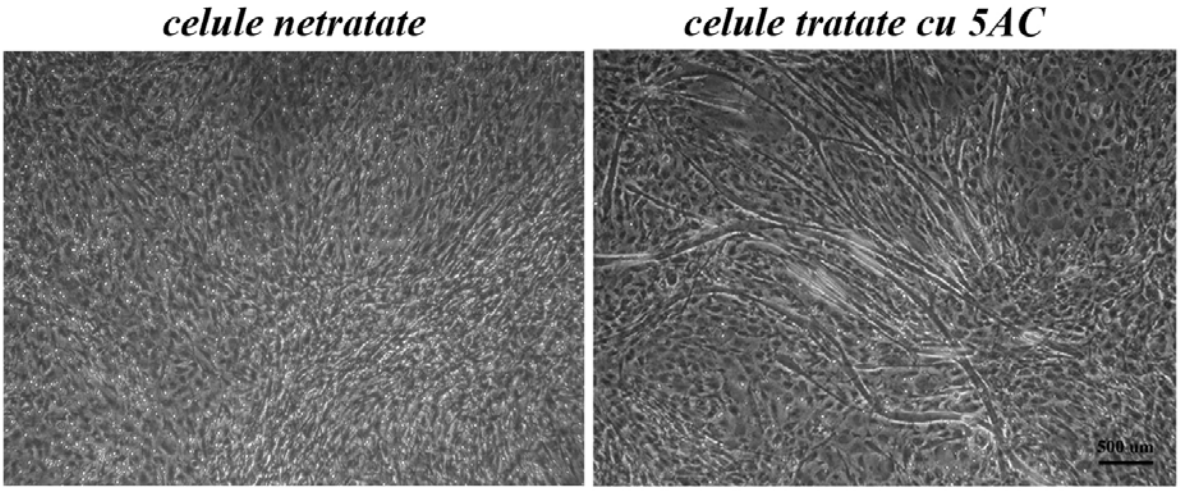

Figura 12: Imagine de microscopie in contrast de faza aratand prezenta miotubilor formati in cultura de celule stem mezenchimale tratate cu 5-azacitidina dupa deprivarea de ser.

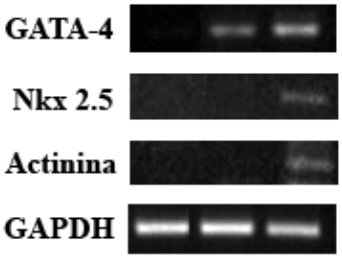
Ca urmare a acestor observații, am considerat că tratamentul cu 5-azacitidină asociat cu contactul direct cu celulele musculare cardiace ar putea avea un efect benefic asupra diferențierii celulelor stromale în CMC. Astfel, în continuare am urmărit modificările apărute în celulele stromale medulare prin contact direct cu celule musculare cardiace. Rezultatele au arată că, într-adevăr, cumularea celor doi factori inductori, a dus la inițierea expresiei unor factori de transcripție specific cardiaci în celule stromale medulare de şoarece, precum GATA-4 şi Nkx2.5 (figura 13). Mai mult, s-a observat că expresia acestuia din urmă a fost indusă doar în cazul cumulării celor două condiții de diferențiere. În plus, în acest caz, a fost evidențiată şi expresia actiniei, un indicator al diferențierii către un fenotip muscular de tip striat.

Mai mult decât atât, rezultatele experimentelor de cocultură în camere duble au arătat ca factorii solubili eliberați de miocardul ischemic împreună cu tratamentul cu 5-azacitidină au avut ca efect creşterea diferențierii celulelor medulare către un fenotip cardiac. Astfel, cumularea expunerii la acțiunea 5-azacitidinei cu semnalele provenite de la țesutul miocardic ischemic au avut ca rezultat inițierea transcrierii unor factori esențiali implicați în procesul de diferențiere cardiomiogenă, cum cum sunt: actina şi actinina caracteristice musculaturii de tip striat, desmina, GATA-4 şi Nkx2.5 şi a canalului de calciu de tip L (figura 14). Astfel, se poate concluziona că inițierea diferențierii indusă de demetilarea anumitor gene este ajutată de efectul unor factori cardiaci solubili, care au capacitatea să finalizeze acest proces.



CSA	+	+	+
CMC	-	+	+

Figura 14: RT-PCR arătând inducerea expresiei genice a markerilor de celule musculare cardiace în prezența cumulării celor doi factori de inducere a diferențierii celulelor stromale medulare adulte în CMC: 5-azacitidina şi factorii locali eliberați de miocardul ischemic.

IV. Evidențierea factorilor cu efec paracrin secretați de celulele stem mezenchimale în condiții normale şi hipoxice

Ultimul capitol al tezei a fost realizat că urmare a informațiilor recente apărute în literatura de specialitate privind rezultatele studiilor clinice. Acestea au arătat faptul că efectele benefice ale transplantului de celule stem în infarctul miocardic sunt tranziente, ceea ce sugerează un efect paracrin exercitat de celulele transplantate, prin intermediul secreției de factori cardioprotectori şi angiogeni. În aceste condiții, ultima parte a tezei a cuprins studiul efectului anti-apoptotic al factorilor solubili eliberați de MSC asupra celulelor musculare cardiace şi identificarea unor factori cu acțiune cardioprotectoare eliberați de MSC în condiții normale şi hipoxice. O observație de o importanță deosebită făcută în urma acestor experimente a fost capacitatea MSC de a se adapta şi de a rezista la condiții hipoxice, fapt demonstrat de rezistența acestor celule la apoptoza indusă de condițiile hipoxice (figura 15).

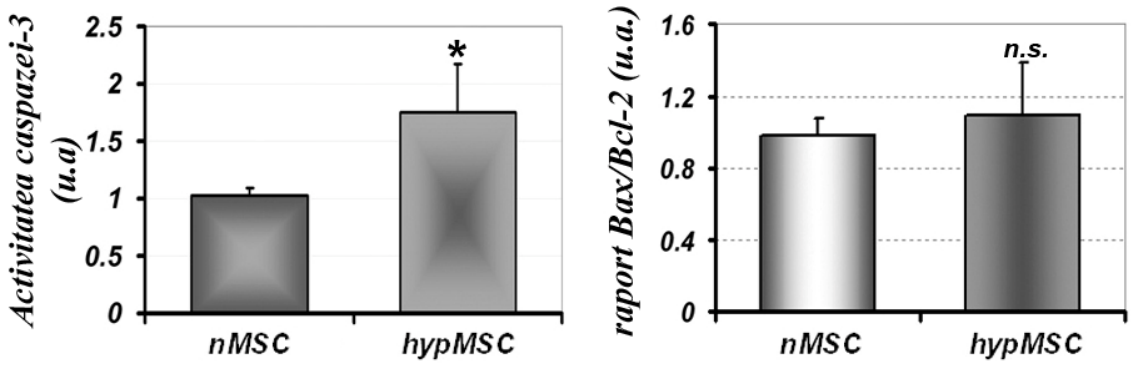

Figura 15: Rezistența MSC în condiții ischemice: graficul din stânga arata o uşoară creştere a activității caspazei-3, în timp de raportul dintre expresia genică a proteinei pro-apoptotice Bax şi proteinei anti-apoptotice Bcl-2, determinat prin PCR cantitativ, rămâne neschimbat (graficul din partea dreaptă).

Rezistența MSC la apotoza indusă de hipoxie are o importanță deosebită pentru supraviețuirea acestora în miocardul infarctizat, în situația în care acesta este lipsit de o vascularizație corespunzătoare asigurării necesarului de oxigen.

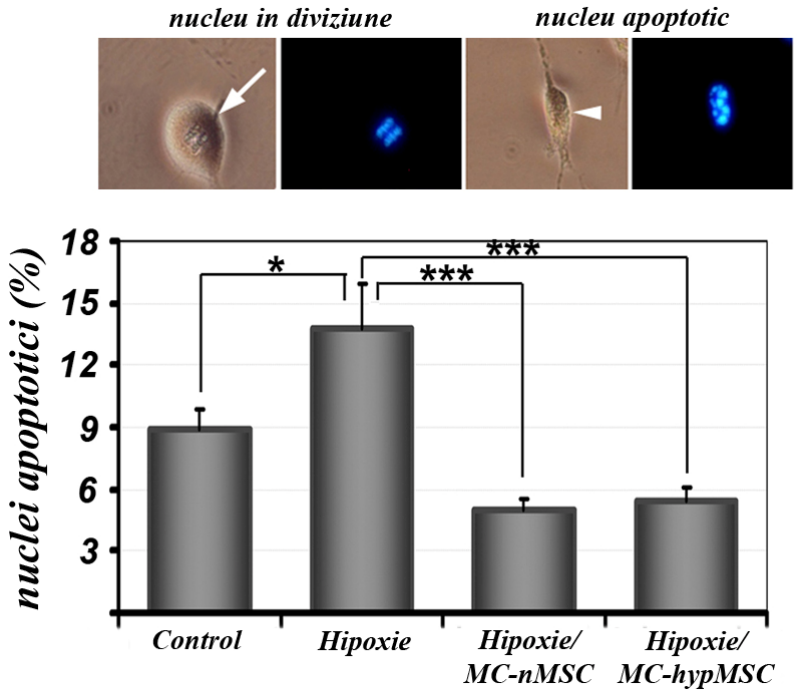

Figura 16: Determinarea cantitativă a apoptozei în miocitele cardiace după expunerea la hipoxie în prezența şi absența mediului condiționat recoltat de la MSC. În graficul din partea de jos sunt prezentate procentele de nuclei apoptotici determinați prin colorație cu Hoechst. Pentru fiecare test au fost numărați cel puțin 1000 de nuclei (, p< 0.05; ***, p< 0.001). În partea de sus sunt prezentate imagini cu nuclei în diviziune comparativ cu nuclei apoptotici.*

Investigarea efectului mediului condiționat al MSC asupra apoptozei CMC indusă de hipoxie a arătat că MSC secretă factori cu acțiune cardioprotectoare. Incubarea CMC în mediu condiționat a prevenit inducerea apoptozei (figura 16). Rezultatele au demonstrat menținerea integrității membranei mitocondriale, fapt ce a contribuit la prevenirea inițierii procesului apoptotic. Mai mult decât atât, mediul condiționat recoltat de pe MSC hipoxice a avut efecte similare cu cel recoltat de pe celule cultivate în 20% O_2, ceea ce demonstrează faptul că MSC îşi păstrează proprietățile cardioprotectoare în condiții hipoxice. Acest rezultat sugerează posibilitatea ca MSC transplantate în miocard hipoxic să contribuie la supraviețuirea CMC afectate atât de hipoxie, cât şi de stressul oxidativ din timpul reperfuziei.

Studiul compozitiei mediului conditionat al MSC a aratat ca aceste celule sunt capabile să îşi păstreze capacitatea de a sintetiza şi a elibera în mediul extracelular unii factori cu efect cardioprotector, cum ar fi unele citokine sau microARN. Au fost identificate astfel o serie de citokine secretate de către MSC incubate în conditi normale, dintre care patru au fost regăsite în

mediul MSC incubate în hipoxie în cantități similare cu controlul: TIMP-1, MCP-1, IL1ra şi SDF-1α (figura 17).

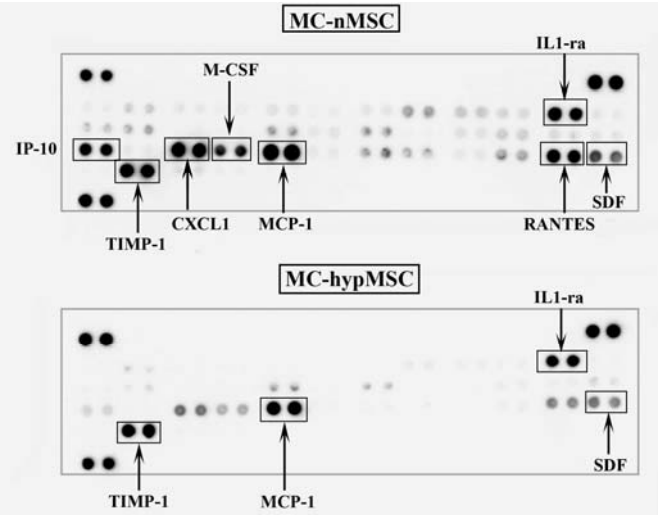

Figura 17: Identificarea citokinelor secretate în mediul condiţionat de către MSC normoxice (partea de sus a imaginii) şi hipoxice (partea de jos) prin tehnica "cytokine array".

Conform datelor din literatură, aceşti factori ar putea fi responsabili, cel puțin în parte, de efectul cardioprotector exercitat de prezența MSC la nivelul miocardului ischemic, fie datorită acțiunii antiapoptotice, fie capacității de a induce procesul de angiogeneză, important pentru restabilirea aprovizionării țesutului cu oxigen şi nutrienți. Pe lângă aceste molecule, se pare că transferul de informație genetică între MSC şi celulele lezate este un mecanism important responsabil de efectul reparator al MSC. Astfel, în mediul extracelular al MSC hipoxice a fost observată o creştere a cantității de microARN 199a şi 1225b, cunoscute pentru efectul anti-apoptotic (figurile 18 si 19).

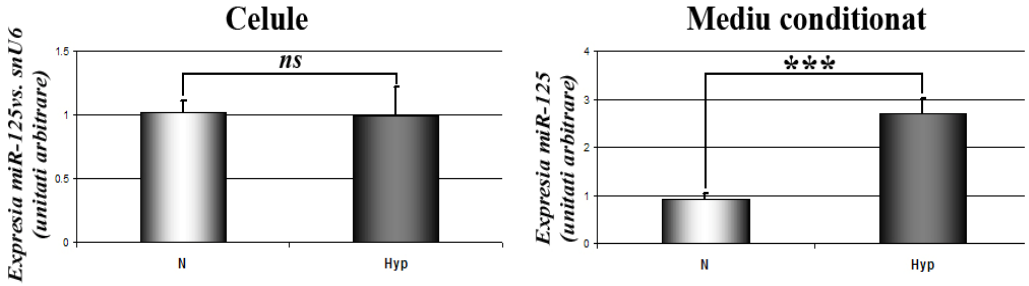

Figura 18: Cuantificarea prin PCR cantitativ a expresiei microRNA-125 în MSC incubate în condiții normoxic şi hipoxice (graficul din stânga), precum şi în mediul extracelular recoltat de pe celulele menținute în cele două condiții (** p<0.0005).*

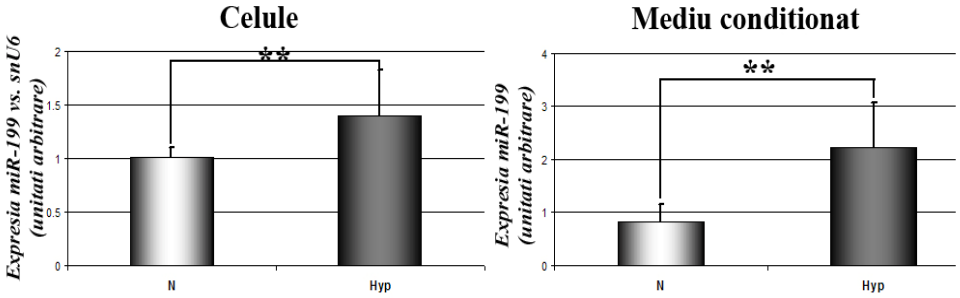

*Figura 19: Cuantificarea prin PCR cantitativ a expresiei microRNA-199 în MSC incubate în condiţii normoxic şi hipoxice (graficul din stânga), precum şi în mediul extracelular recoltat de pe celulele menţinute în cele două condiţii (** p<0.005).*

În concluzie, compoziția mediului extracelular al MSC consta într-un amestec de factori cu efect fie anti-apoptotic (TIMP-1, MCP-1, miR-199a, miR-125b), fie de inhibare a proliferării fibroblastilor (IL1ra) sau angiogenic (SDF-1α). Prezența acestor factori cardioprotectori în secreția MSC ar putea fi responsabilă de efectul anti-apoptotic asupra CMC hipoxice observat în condițiile noastre experimentale.

Concluzii

Informațiile cuprinse in lucrarea de doctorat reprezintă rezultate, concretizate în articole publicate în reviste internaționale cu factor de impact ISI, prezentări orale sau sub formă de poster la manifestări ştiinţifice naţionale şi internaţionale. Pe parcursul perioadei de doctorat, în urma experimentelor realizate, au fost obținute următoarele rezultate importante:

- S-a demonstrat că principalul factor inductor al apoptozei CMC în urma ischemiei miocardului este reprezentat de oxidanții exogeni aduşi de reperfuzie;
- S-a pus la punct o metodă de obținere a unei populații de celule progenitoare obținute prin fracționarea aspiratului medular prin centrifugare pe gradient discontinuu de Percoll;
- S-au obținut culturi omogene de MSC, care au îndeplinit standardele de caracterizare indicate de Societatea Internațională de Transplant Celular;
- A fost arătat efectul acțiunii demetilante a 5-azacitidinei asupra caracterului pluripotent al MSC;
- A fost demonstrat efectul îmbunătățit al cumulării acțiunii 5-azacitidinei cu factorii eliberați de miocard pentru creşterea diferențierii MSC către un fenotip cardiac;

- A fost demonstrat efectul anti-apoptotic al factorilor eliberați de MSC normale şi hipoxice asupra CMC;
- Au fost identificați factori cu acțiune anti-apoptotică, anti-fibrotică şi pro-angiogenă în mediul extracelular al MSC normale şi hipoxice, posibil responsabili de acțiunea cardioprotectoare a acestor celule.

Partea I

STADIUL ACTUAL AL CUNOSTINTELOR PRIVIND PROCESUL INFLAMATOR ASOCIAT PATOLOGIEI CARDIOVASCULARE

I. Caracteristici ale procesului inflamator asociat patologiei cardiovasculare

I. 1. Mecanisme inflamatorii in aterogeneza

I. 2. Rolul efectorilor imunitatii inascute si a sistemului imun adaptativ in procesul inflamator asociat aterosclerozei

I. 3. Receptori/mediatori ai procesului inflamator

I.3. 1. Pentraxinele imunomodulator in aterogeneza

I.3. 2. Toll-like receptor (TLR) implicati in inflamatia vasculara

I.3. 3. Receptorii citoplasmatici NOD (nucleotide-binding domain-like); asocierea sistemului inflamazom in sinteza de citokine inflamatorii

II. Rolul citokinelor in modularea inflamatiei vasculare; mecanisme de semnalizare induse de citokinele pro-inflamatoare

II. 1. TNF-α modulator al inflamatiei in celulele peretelui vascular

II. 2. Interleukinele familiei IL-1 exacerbeaza inflamatia vasculara

II. 3. Interleukina-6 (IL-6) factor de risc in boala cardiovasculara

II. 4. Rolul semnalizarii trans in inflamatia cardiovasculara

II. 5. Rezistina – rol in inflamatia asociata bolilor cardiovasculare

II. 6. STAT - mediator al semnalizarii induse de cross-talkul dintre IFN-γ si TLR in boala cardiovasculara

II. 7. Reglatorii semnalizarii induse de citokine

III. Chemokinele - mediatori ai interactiei celule vasculare-leucocite; markeri in boala cardiovasculara

III. 1. Inflamatia vasculara modulata prin axa chemokina/receptor *MCP-1* (CCL2)/ *CCR2*

III. 2. Axa CX3CL1/CX3CR1 - implicatie in “cross-talk-ul” dintre celulele vasculare-leucocite

IV. Diabetul – factor de risc cardiovascular

IV. 1. Mecanisme pro-aterogene asociate hiperglicemiei

Partea II CONTRIBUTII ORIGINALE

- **Obiective**

I. Glucoza crescuta induce expresia fractalkinei si „monocyte chemotactic protein-1” (MCP-1) in celulele musculare netede

Cuvinte cheie: boli cardiovasculare, atersoscleroza, inflamatie, markeri ai inflamatiei, citokine, chemokine, diabet, rezistina, fractalkina, MCP-1, celule musculare netede vasculare umane, monocite, comunicare inter-celulara, MAPK-kinaze, factori de transcriptie inflamatori, promotor.

Bolile cardiovasculare alaturi de aliatul principal, disfunctia metabolica, reprezinta principala problema socio-medicala din tarile dezvoltate. Numarul pacientilor cu boli cardiovasculare este in continua crestere, ceea ce impune imbunatatirea algoritmului de prognostic prezent prin identificarea unor factori de risc moleculari strans corelati cu statusul bolii si elucidarea mecanismelor celulare si moleculare asociate acestora, precum si identificarea unor noi strategii terapeutice. Factorii de risc traditionali implicati in dezvoltarea patologiilor cardiovasculare sunt diabetul, hiperlipidemia, obezitatea, hipertensiunea iar de curand, procesele inflamatorii au fost si ele asociate.

Procesul patologic fundamental si principala cauza a bolilor cardiovasculare este **ateroscleroza.** Ateroscleroza este boala multifactoriala a carei patogeneza nu este inca deplin inteleasa, insa inflamatia si procesele sale celulare complexe joacă un rol important in progresia leziunii. Ateroscleroza implica interactii complexe intre celulele inflamatorii (neutrofile, limfocite, monocite/macrofage) si celulele vasculare (celulele endoteliale, celulele musculare netede). Inflamatia este factor de risc independent pentru procesle aterosclerotice dar mecanismele implicate sunt inca necunoscute.

Mecanismele imuno-inflamatoare sunt direct implicate in initierea si progresia bolilor cardiovasculare (CV) de la stadiul incipient asimtomatic de *injurie vasculara*, la manifestarile clinice de *disfunctie si remodelare vasculara*. Deoarece injuria vasculara este in parte reversibila identificarea fenotipului inflamator este esentiala pentru suprimarea proceselor inflamatorii, precum si in dezoltarea noilor strategii terapeutice. Procesul inflamator din leziunea aterosclerotica implica participarea unor *efectori moleculari* (receptori “pattern recognition”, molecule inflamatorii bioactive) si a unor *efectori celulari* (monocite/macrofage, limfocite, celule prezentatoare de antigen si celule dentritice). Mai mult, mediatorii implicati in modularea proceselor inflamatoare pot fi ***markeri ai proceselor inflamatorii vasculare***, dar si potentiale tinte terapeutice. Prin tehnologiile avansate de proteomica, metabolomica si genetica s-au: i) identificat biomarkeri prezumtivi sau factori de risc; ii) dezvoltat tinte terapeutice, iii) imbogatit eficienta terapiile dezvoltate anterior; astfel ca, unii biomarkeri sunt etalon experimental, strans corelati cu statusul bolii. Evidentierea mecanismelor moleculare de semnalizare specifice implicate in expresia si actiunea acestor markeri in celulele peretelui vascular nu au fost inca elucidate.

In incercarea de a aduce noi date care sa contribuie la descifrarea mecanismelor inflamatorii asociate aterosclerozei, lucrarea de fata isi propune sa identifice mecanismele moleculare implicate in modularea raspunsului inflamator din celulele peretelui vascular. Identificarea mecanismelor moleculare inflamatorii este necesara pentru "screeningul" timpuriu al pacientilor cu boala cardiovasculara, in monitorizarea terapiei anti-inflamatoare prin cuantificarea biomarkerilor inflamatori dar si in dezvoltarea unor terapii tintite.

In prima parte a tezei „ Stadiul actual al cunostintelor", sunt prezentate pe parcursul a patru capitole diferite caracteristici ale procesului inflamator asociat patologiei cardiovasculare.

Capitolul I descrie mecanismele inflamatorii asociate aterogenezei precum si rolul efectorilor imunitatii inascute si a sistemului imun adaptativ in procesul inflamator. Mecanismele imunitatii inascute au rol central in initierea aterosclerozei prin activarea receptorilor "pattern-recognition" (PRR) care favorizeaza raspunsul inflamator. Ca raspuns al legarii si activarii PRR sunt eliberati *efectori ai imunitatii inascute* precum *peptide* (CRP, sistemul complement), *oxidul nitric* (NO), *eicosanoizii (*prostaglandine si leucotriene*)* si *molecule inflamatoare* (citokine,chemokine). De asemenea, studii multiple indica si rolul important al raspunsului ***antigen-specific*** in procesul aterosclerotic modulat prin efectori ai imunitatii adaptative. Astfel, sistemul imun adaptativ poate influenta procesele aterogene pe trei cai diferite: i) *interactii celula-celula* intre celula prezentatoare de antigen, macrofage, limf B sau CD si limf T; ii) *eliberare de citokine* prin limf T activate care mediaza activarea macrofagelor si a altor celule din placa; iii) *secretie anticorpi* prin limf B dependent /independent de limf T.

Capitolul al-II-lea prezinta rolul citokinelor in modularea inflamatiei vasculare si mecanismele de semnalizare induse de citokinele pro-inflamatoare. Nivelul crescut de citokine mentine statusul inflamator asociat disfunctiei vasculare in boli precum ateroscleroza, hipertensiune, aneurismul aortic abdominal si vene varicoase. Efectele biologice ale citokinelor pro-inflamatoare TNF-α, IL-1 si IL-6 se reflecta in mecanismele inflamatorii asociate aterosclerozei.

Capitolul al-III-lea descrie **chemokinele** ca mediatori in interactia celulelor vasculare-leucocite. Chemokinele sunt modulatori chemoatractanti pentru diferitele subpopulatii de leucocite dar si pentru celulele nonhematopoetice (CMN), ca raspuns la stimuli activatori. Chemokinele si receptorii specifici alcatuiesc un sistem chemokinic complex, care atrage subseturi leucocitare specifice in fiecare etapa a procesului aterogen. Recrutarea subseturilor leucocitare la situsul inflamator implica diverse chemokine, angajate in interactii heterofile favorizate de proteoglicani. Studii recente au aratat ca nivelul circulant al chemokinelor poate fi asociat diverselor boli inflamatorii precum iar ***MCP-1*** este factor de prognostic independent in sindromul coronar acut. Inflamatia vasculara poate fi modulata prin axa chemokina/receptor ***MCP-1***(CCL2)/***CCR2*** iar strategii precum terapia genica (*mutant de deletie a genei MCP-1*) sau tintirea farmacologica diminueaza raspunsul inflamator astfel, MCP-1 poate fi atat **marker de prognostic** cat si **tinta**

terapeutica. De asemenea ***axa CX3CL1/CX3CR1*** poate fi implicata in dialogul dintre celulele vasculare-leucocite, studii imunohistochimice au confirmat prezenta axei CX3L1/CX3CR1 la nivelul placii aterosclerotice coronare (monocite/macrofage, CE, CMN). Celulele musculare netede (CMN) din neointima placii aterosclerotice exprima CX3CR1 ceea ce demonstreaza ca, CMN migreaza din media datorita CX3CR1, dependent de gradientul de CX3CL1 din intima. Axa CX3L1/CX3CR1 mediaza ancorarea monocitelor/macrofage la CMN din placa ceea ce sustine capacitatea de tintire terapeutica a acestei cai pro-inflamatorii in boala cardiovasculara. In concluzie, *sistemul Fk/CX3CR1* poate fi considerat cea mai promitatoare tinta pro-inflamatoare pentru interventia terapeutica in procesul aterosclerotic iar mecanismele de semnalizare intracelulara trebuie pe deplin intelese pentru a dezvolta o noua clasa de agenti anti-inflamatori.

Capitolul al-IV-lea prezinta diabetul ca factor de risc cardiovascular major independent, asociat complicatiilor micro/macrovasculare prin accelerarea proceselor aterosclerotice. Atat diabetul cat si ateroscleroza sunt conditii multifactoriale care par sa aiba o baza inflamatoare comuna, deoarece in ambele patologii sunt eliberati *markeri inflamatori de faza acuta* (CRP, IL-6 acid sialic, amiloid A, cortizon) specifici imunitatii inascute. Mecanismele pro-aterogene asociate hiperglicemiei din celulele peretelui vascular sunt detaliate pe larg in acest capitol.

In incercarea de a descifra atat mecanismele celulare si moleculare ale inflamatiei asociata proceselor aterosclerotice, cat si a elabora o strategie terapeutica care sa diminueze acest process cu rol important in initierea ulterioara a bolii cardiovasculare, lucrarea de fata s-a concentrat in cadrul partii a II-a a tezei ”Contributii originale” pe urmatoarele obiective principale:

I. Rolul concentratiei crescute de glucoza in exacerbarea inflamatiei in celulele musculare netede; efectul fibratilor (activatori de PPARα) in modularea expresiei si functiei de chemokine (MCP-1 si fractalkina)

II. Evidentierea cailor de semnalizare celulare prin care glucoza regleaza expresia chemokinelor MCP-1 si fractalkina in celulele musculare netede

III. Studiul interactiei dintre celulele musculare netede si monocite in modularea expresiei moleculelor pro-aterogene; evidentierea rolului axei CX3CL1-CX3CR1 in medierea interactiei celulare

IV. Cai de semnalizare implicate in interactia CMN-monocit dependent de axa CX3CL1/CX3CR1

V. Rolul rezistinei in modularea fenotipului celulelor musculare netede; mecanisme moleculare implicate in actiunea rezistinei la nivelul celulelor musculare netede vasculare.

VI. Caracterizarea promotorului functional de fractalkina

In **capitolul I** am inclus studiile cu privire la efectele concentratiei crescute de glucoza in modularea expresiei de fractalkina si MCP-1 in celulele musculare netede si rolul functional al acestor chemokine, si anume, adeziunea si chemotaxia monocitelor la celule activate de glucoza

crescuta. In plus, am urmarit efectul activatorilor de PPARα (fenofibrat si clofibrat) asupra expresiei de fractalkina si MCP-1 in celulele musculare netede umane expuse la concentratie crescuta de glucoza dar si mecanismele de semnalizare implicate in actiunea glucozei crescute in aceste celule.

Rezultatele acestui studiu au aratat ca nivelelul crescut de glucoza induce expresia fractalkinei si a MCP-1 in celulele muscular netede umane direct proportional cu concentratia de glucoza. Rezultatele obtinute sustin studiile anterioare care au identificat prezenta fractalkinei in intima vaselor. Mai mult, activatorii PPARα, ***fenofibratul*** si ***clofibratul*** reduc expresia genica si proteica a MCP-1 si fractalkinei in CMN activate de glucoza crescuta. Efectul glucozei asupra chemokinelor MCP-1 si fractalkina se reflecta la nivel functional prin numarul crescut de monocite aderate la CMN. Procesul de adeziune al monocitelor la CMN activate de glucoza este dependent de aceste chemokine, intrucat inhibarea semnalizarii cu *toxina pertussis* reduce numarul monocitelor aderate in conditii de flux laminar continuu. In particular, rolul MCP-1 si fractlkinei este subliniat de experimentele in care receptorii specifici ai acestor chemokine au fost blocati (prin incubare cu anticorpi specifici), ceea ce condus la diminuarea numarului de monocite aderate.

Mecanismul de semnalizare implicat in supraexpresia MCP-1 si fractalkinei indusa de glucoza crescuta determina activarea protein kinazele ERK1/2 si p38MAPK si a factorilor de transcriere NF-kB si AP-1, dependent de speciile reactive de oxigen eliberate (ROS). Inhibarea speciilor reactive de oxigen cu *PDTC* si *DPI* reduce activarea ERK1/2 si p38 MAPK sugerand implicarea stresului oxidativ in activarea MAPK. De asemenea inhibarea kinazelor p38MAPK si a ERK1/2 cu inhibitori specifici (SB203580 sau PD98095), reduc complet fosforilarea ***IkBα*** si a ***c-jun*** sugerand rolul p38MAPK si p42/44MAPK in activarea NF-kB, respectiv AP-1. Mai mult, am studiat rolul NF-kB si AP-1 in expresia fractalkinei si MCP-1, prin transfectia CMN cu oligodeoxinucleotide de competitie pentru p65 si c-Jun. Blocarea situsurilor de legare NF-kB si AP-1 reduce expresia proteica a MCP-1 si fractalkinei, sugerand implicarea factorilor de transcriptie in modularea ambelor chemokine. Clofibratul si fenofibratul diminueaza fosforilarea/activarea kinazelor p38MAPK si ERK1/2, astfel ca este impiedicata translocarea factorilor de transcriptie NF-kB si AP-1 respectiv eliberarea de MCP-1 si fractalkina.

In concluzie, studiile din acest capitol demonstreaza ca activarea CMN vasculare prin supraexpresia acestor chemokine, induce cresterea interactiilor adezive dintre monocite si CMN, studiu ce poate explica unul din mecanismele aterosclerozei accelerate indusa in conditii diabetice.

In **capitolul II** am investigat rolul axei ***CX3CL1/CX3CR1*** in dialogul dintre celulele musculare netede si monocite dar si implicarea acestei cai in exacerbarea expresiei de molecule proinflamatoare, bazandu-ne pe studii anterioare care atesta prezenta fractalkinei si receptorul sau la nivelul placii aterosclerotice coronare. Astfel am presupus ca interactia dintre CMN si monocite se

poate realiza prin intermediul *fractalkina-CX3CR1* ceea ce poate influenta fiecare tip celular prin modularea moleculelor inflamatoare cu rol important in progresia placii aterosclerotice.

Rezultatele obtinute demonstreaza arata ca interactia dintre CMN si monocite sau CMN si monocite activate cu LPS (lipopolizaharide) creste expresia moleculelor TNFα, IL-1β, IL-6, CX3CR1 si MMP-2,-9 in ambele tipuri celulare iar activarea suplimentara a monocitelor cu LPS exacerbeaza expresia TNFα, CX3CR1 si MMP-9. Modularea expresiei TNFα, CX3CR1 si MMP-9 este dependenta de *axa fractalkina-CX3CR1* pe cand expresia IL-6, IL-1β si MMP-2 este independenta de legarea acestei perechi receptor-ligand. Interactia monocite-CMN activeaza kinaza p38MAPK care succesiv transduce factorii de transcriptie NF-kB si AP-1 care ulterior faciliteaza producerea moleculelor pro-aterogene (citokine si MMP). Comunicarea dintre CMN si monocite prin legarea fractalkinei la receporul sau este dependenta de transductia factorului de transcriptie ***AP-1*** implicat in reglarea expresiei moleculelor pro-aterogene TNFα, CX3CR1 si MMP9.

Datele in acest studiu extind rolul cunoscut al fractalkinei si receptorului acesteia si sugereaza ca in placa aterosclerotica, comunicarea directa intre celulele musculare netede si monocite amplifica raspunsul inflamator prin *axa fractalkina–CX3CR1* care functioneaza ca inducator al unor molecule critice pentru progresia ateromului. Astfel, perechea CX3CL1-CX3CR1 poate constitui o noua tinta terapeutica pentru a reduce procesul inflamator asociat aterosclerozei.

In **capitolul III** am urmarit efectul inflamator al rezistinei in celulele musculare netede prin modularea expresiei de fractalkina si CX3CR1 dependent de receptorul TLR4.

Scopul acestui studiu a fost de a investiga rolul rezistinei ca modulator al fenotipului CMN respectiv, efectele pro-inflamatorii exercitate. Intrucat rezistina si fractalkina sunt prezente in leziunea aterosclerotica iar receptorul CX3CR1 este predominant asociat CMN am emis ipoteza ca rezistina poate fi inductor al expresiei de fractalkina (CX3CL1) si contribuie pe aceasta cale atat la modularea fontipica (pro-inflamatorie) a CMN cat si la intensificarea transmigrarii monocitelor.

Rezultatele arata ca rezistina poate induce semnificativ expresia CX3CL1 si CX3CR1 in CMN vasculare ceea ce demonstreaza ca, rezistina poate fi o citokina operatioanala in inducerea statusului pro-inflamator si contribuie astfel la dezvoltarea aterosclerozei. Intrucat receptorul rezistinei in celulele vasculare nu este inca cunoscut rezultatele experimentale din acest studiu demonstreaza ca la nivelul CMN vasculare atat anti-TLR4 cat si PTX inhiba expresia CX3CL1 si CX3CR1 indusa de rezistina, ceea ce sugereaza ca rezistina poate utiliza atat receptorii TLR4 cat si receptorii proteinelor-Gi in modularea acestor molecule.

Pe langa acestea, rezultatele acestui studiu arata ca rezistina activeaza p38MAPK si STAT3 dar nu ERK1/2. Inhibitorii farmacologici ai p38MAPK reduc semnificativ expresia CX3CL1 si CX3CR1 in CMN activate cu rezistina. Activarea p38MAPK de catre rezistina poate induce translocarea subunitatilor p65 si c-Jun a factorilor de transcriptie NF-kB si AP-1. Mai mult, inhibitorul *SP100030* (dublu inhibitor al NF-kB si AP-1) reduce fractalkina si CX3CR1,

demonstrand rolul NF-kB si AP-1 in reglarea lor. Silentierea p65 si c-Jun anterioara activarii cu rezistina, reduce semnificativ expresia celor doua molecule. Coroborate aceste rezultate indica ca NF-kB si AP-1 sunt implicate in actiunea rezistinei asupra expresiei de fractalkina si a receptorului specific la nivelul CMN vasculare. De asemenea, rezultatele arata ca blocarea caii JAK/STAT cu inhibitor specific *WP-1066* dar si silentierea STAT1/STAT3 cu ODN specifice, reduc expresia CX3CL1 si a receptorului sau, ceea ce demonstreaza ca factorii de transcriptie STAT sunt implicati in acest proces aditional la actiunea NF-kB si AP-1.

Experimentele de chemotaxie realizate prin sistemul xCELLigence demonstreaza ca fractalkina indusa de rezistina este functionala in transmigrarea monocitelor. Mediul conditionat colectat de la CMN activate cu rezistina confera un semnal chemoatractant puternic pentru monocite. Aditia anticorpului anti-CX3CL1 in mediul conditionat al CMN activate cu rezistina, reduce semnificativ numarul monocitelor transmigrate. Toate aceste rezultate arata ca efectul chemotactic al fractalkinei solubile eliberate in mediul conditionat este dependent de expresia/interctia cu receptorul CX3CR1 de pe monocite.

In **capitolul IV** am conceput experimente pentru a evidentia daca activitatea promotorului si expresia CX3CL1 este reglata prin mecanisme directe/indirecte de factorii de transcriptie NF-kB, AP-1 si STAT1/STAT3.

Analiza ***in silico*** a **promotorului uman *CX3CL1*** indica existenta elementelor promotor-specifice *TATA* si *CCAC box*. Aditional, au fost identificate situsuri de legare relevante pentru fiziologia si patologia vasculara ce includ ***NF-kB***, ***AP-1***, ***GAS*** (STAT1/STAT3), ***C/EBP***, ***GATA***, si ***GAGA***. Analiza mutantilor de deletie a CX3CL1 arata ca NF-kB, AP-1 si STAT1/STAT3 nu sunt esentiali in activitatea de baza a promotorului in CMN dar au rol in modularea CX3CL1 ca raspuns la stimuli inflamatori. Pentru a investiga functia elementelor NF-kB, AP-1 si GAS am analizat activitatea nucleara a factorilor de transcriptie prin tehnica ChIP in CMN tratate cu rezistina. Rezultatele arata ca secventele prevazute prin analiza *in silico* corespunzatoare AP-1, NF-kB si GAS formeaza complexe de legare cu c-Jun, p65 si STAT1/STAT3. Rezultatele obtinute arata numeroase interactii *non-canonice* intre proteinele p65/NF-kB, c-Jun/AP-1 si STAT1/STAT3.

In concluzie, aceste rezultate prezinta pentru prima data o caracterizare a promotorului CX3CL1uman. Rezultatele demonstreaza ca interactia complexa intre NF-kB, AP-1 sau STAT1/3 si caile asociate regleaza direct/indirect CX3CL1, mecanism ce poate fi responsabil de supraexpresia CX3CL1 in placa aterosclerotica umana. Acesti factori de transcriptie sunt esentiali pentru transducerea multor factori de risc cardiovascular iar modularea reglatorilor “up-stream” de promotorul CX3CL1 poate reprezenta o strategie farmacologica eficienta pentru a atenua actiunea puternic proinflamatorie a CX3CL1.

Coroborate toate aceste rezulate obtinute in partea “ Contributii originale”subliniaza importanta interactiilor complexe dintre factorii de transcriptie, coactivatori, si/sau corepresori in

supraexpresia fractalkinei. Inhibarea chimica a cailor kinazice “up-stream” (p38MAPK, JNK si JAK2) precum si suprimarea factorilor de transcriptie NF-kB, AP-1 si STAT1/3 prin tehnologia ARN de interferenta reduc expresia de fractalkina indusa depndent de rezistina sau glucoza crescuta. Toate aceste rezultate arata importanta cailor de semnalizare ***NF-kB***, ***AP-1*** si ***STAT1/3*** in reglarea expresiei CX3CL1, ceea ce explica prezenta ei in leziunea umana aterosclerotica dependent de expresia rezistinei secretata la nivelul leziunii prin macrofage sau conditiile hiperglicemice din diabet.

Intrucat teza aceasta are un caracter predominant fundamental, scopul final al acestor studii este de natura aplicativa. Seria de experimente realizate pot contribui la elucidarea mecanismelor inflamatorii de la nivelul placii aterosclerotice, respectiv la optimizarea unor terapii care sa reduca dinamica proceselor inflamatorii.

Cuvinte cheie: Valvă aortică, inflamație, diabet, glucoză, hidrogel

Boala valvei aortice (BVA) reprezintă o problemă de sănătate la nivel mondial și una dintre cauzele majore ale mortalității în rândul persoanelor de peste 65 de ani (Nkomo, Gardin et al. 2006, Yadgir, Johnson et al. 2020, Coffey, Roberts-Thomson et al. 2021). Pentru mult timp BVA a fost considerată un proces pasiv, degenerativ, deoarece progresia bolii se întinde pe parcursul a zeci de ani. În prezent, boala este recunoscută drept un proces activ, condus de inflamația cronică, asemănător în fazele inicipiente cu ateroscleroza. Terapia cu statine s-a dovedit însă ineficientă în ameliorarea BVA, arătând astfel că mecanismele de progresie ale celor două patologii sunt diferite(Cowell, Newby et al. 2005).

Evoluția BVA cuprinde *scleroza timpurie*, caracterizată prin îngroșarea cuspelor dar fără consecințe asupra funcției, și *stenoza târzie*, când funcția valvei este compromisă din cauza depozitelor extinse de calciu. Detecția clinică a valvelor stenotice se face prin identificarea unui murmur cardiac și este confirmată ecocardiografic, bazându-se astfel pe simptomele din stadiile avansate când structura și funcția valvei sunt afectate(Lindman, Bonow et al. 2013). În prezent, nu există markeri predictivi sau terapii farmacologice pentru gestionarea BVA, iar singura opțiune de tratament pentru valvele aflate în stadii avansate de calcificare este înlocuirea chirurgicală a acestora cu proteze mecanice sau biologice, care la rândul lor se pot calcifica. Se estimează că, odată cu îmbătrânirea populației, incidența BVA o să crească semnificativ, mai ales în țările dezvoltate, devenind o importantă problemă socio-economică(Kodali, Velagapudi et al. 2018). Diabetul este unul dintre factorii de risc cunoscuți pentru dezvoltarea BVA, iar acesta a fost asociat recent cu progresia accelerată a bolii și gravitatea simptomelor la pacienții cu stenoză aortică moderată(Han, Shi et al. 2021, Manduteanu, Simionescu et al. 2021, Natorska 2021). Astfel, în diabet, valva aortică (VA) se calcifică accelerat, ceea ce duce la disfuncția valvei și a inimii prin mecanisme care sunt incomplet înțelese.

Prezenta teză a fost structurată în două părți, și anume partea I, “Stadiul actual al cunoaşterii”, unde este prezentată o analiză a literaturii de specialitate necesară pentru a pune în context cercetarea și partea II, “Contribuții originale”, unde este descrisă cercetarea experimentală propriu-zisă.

Astfel, în **prima parte** sunt abordate aspecte legate de dezvoltarea valvei în stadiile embrionare și postnatale, structura și arhitectura valvei aortice, celulele rezidente si rolul lor fiziologic, mecansimele declanșate la nivel celular în patologia valvulară asociată diabetului și o trecere în revistă a modelelor *in vivo* și *in vitro* utilizate pentru studiul valvulopatiei aortice.

Dezvoltarea, structura și celulele rezidente din valva aortică

Valva aortică (VA) este una dintre cele patru valve de la nivelul inimii care asigura curgerea unidirecțională a sângeluri din ventriculul stâng către aortă. **Dezvoltarea VA** are loc atât în perioada embrionară, în fazele de formare ale structurilor anatomice la nivelul inimii, cât și în perioada postnatală, când are loc stabilizarea populațiilor celulare și definitivarea arhitecturii valvei. În etapa embrionară, formarea valvelor cardiace are loc atunci când la nivelul tubului cardiac se formează pernuțele endocardice prin semnalizarea mediată de proteinele morfogenetice osoase (BMP-uri) din superfamilia factorilor de creștere transformanți β (TGF-β). O sub-populație de celule endoteliale endocardice intră în tranziție endotelial-mezenchimală (EndMT) și migrează în jeleul cardiac unde proliferează și dă naștere populației de celule valvulare interstițiale (VIC) din pernuțele endocardice (O'Donnell and Yutzey 2020). În aceste valve embrionare începe un proces complex de remodelare orchestrat de către VIC, care este finalizat în perioada postnatală când valva capătă structura trilaminară caracteristică, iar populația de celule rezidente se stabilizează(Hinton, Lincoln et al. 2006, Nordquist, LaHaye et al. 2018).

Cuspele valvei mature sunt structuri avasculare, la nivelul cărora se disting trei straturi cu **organizare și compoziție** diferită în elemente de matrice extracelulară (MEC): (1) fibrosa – situat spre aortă, și care este compus în principal din fibre de colagen de tip I și III orientate circumferențial, conferind rezistență mecanică valvei; (2) ventricularis – situat spre ventricul, fiind în principal compus din fibre de elastină orientate radial care conferă elasticitate țesutului; (3) spongiosa – stratul din mijloc, compus în principal din proteoglicani (PG), glicozaminoglicani (GAG) și fibre de colagen, care absoarbe șocurile mecanice și servește drept interfață între celelalte două straturi.

Cele trei straturi ale cuspelor VA sunt populate de **celulele rezidente valvulare**, iar studii recente au arătat ca acestea sunt în proporție de 80-85% VIC (negative pentru CD31 și CD45), 5-7% VEC și ∼10% celule de origine imună (Hulin, Anstine et al. 2018, Hulin, Hortells et al. 2019).

Celulele endoteliale valvulare (**VEC**) sunt dispuse sub forma unui monostrat compact care căptușește la exterior cele trei cuspe ale VA și asigură interfața de comunicare dintre sânge și interstițiul valvular. Principala funcție a endoteliului este cea de barieră selectivă și neaderentă, care intermediază transportul de oxigen și nutrienți din sânge către spațiul interstițial, dar și răspunsul imun. VEC sunt o populație de celule endoteliale diferită de celulele endoteliale vasculare și prezintă heterogenitate ridicată: VEC de pe cele două

fețe ale cuspelor sunt diferite, astfel că endoteliul de pe fața ventricularis exprimă inhibitori ai calcificării cardiovasculare iar cel de pe fața fibrosa prezintă profil puternic antioxidativ și exprimare crescută a sintazei endoteliale a oxidului nitric (eNOS)(Simmons, Grant et al. 2005). În patologie, VEC sunt implicate în inițierea și progresia bolii VA prin recrutarea de celule imune, dereglarea semnalizării protective a oxidului nitric (NO) sau prin inițierea tranziției endotelial-mezenchimală (EndMT) (Ma, Zhao et al. 2020, Majumdar, Manivannan et al. 2021).

În valva adultă sănătoasă, populația de celule interstițiale constă majoritar din **VIC** neactivate (qVIC) distribuie în toate cele 3 straturi ale cuspelor, resposabile de menținerea structurii trilaminare a MEC (Bogdanova, Zabirnyk et al. 2019). Celulele interstițiale formează în valvă o rețea celulară extinsă care facilitează răspunsul unitar și transmiterea rapidă de informații între membrii rețelei. Ca răspuns la stimulii mecanici sau patologici, qVIC se pot diferenția în: (1) aVIC, care exprimă metaloproteaze și sunt implicate în remodelarea matricei extracelulare, provocând scleroza timpurie sau (2) obVIC, implicate în acumularea depozitelor de calciu (Rutkovskiy, Malashicheva et al. 2017).

Celulele imune se stabilesc în valvă încă din fazele de dezvoltare a inimii și reprezintă a treia populație majoritară din VA. În valvele murine au fost identificate limfocite T, celule dendritice, mastocite și două subpopulații de macrofage: Mφ1 și Mφ2 (Hulin, Hortells et al. 2019). Deși rolul celulelor imune în menținerea homeostaziei VA nu a fost încă studiat și descris în detaliu, se presupune că acestea patrulează țesutul valvular, fagocitează celule apoptotice sau agenții patogeni și migrează în organele limfoide unde inițiază răspunsul imun prin prezentarea antigenului (Hajdu, Romeo et al. 2011).

Implicarea diabetului în patologia BVA

Diabetul zaharat induce și accentuează răspunsul inflamator și acumularea de lipide asociate cu inițierea și progresia BVA (Manduteanu, Simionescu et al. 2021), iar studiul CANHEART a implicat diabetul ca factor semnificativ de risc în dezvoltarea stenozei aortice (Yan, Koh et al. 2017). Diabetul nu numai că predispune la BVA, dar se asociază de asemenea cu progresia accelerată a bolii și gravitatea simptomelor la pacienții cu stenoză aortică moderată (Aronow, Ahn et al. 2001). Patologia diabetului asociat cu alte boli cardiovasculare este complexă și se datorează în parte efectelor hiperglicemiei, care duce la creșterea generării speciilor reactive de oxigen (ROS) și promovarea exprimării de citokine și chemokine cu efect proinflamator (Dludla, Joubert et al. 2017, Wang, Liu et al. 2021).

Nivelul crescut al proteinei C reactive și hiperlipemia asociată diabetului favorizează inflamația cronică (Dongway, Faggad et al. 2015). Există numeroase dovezi care implică

proteine al căror nivel este crescut în diabet (TNF-α, MCP-1, IL-1β) în patologia valvei aortice (Keane, Calton et al. 2017), astfel că se poate specula că **mediul inflamator** produs în diabet declanșează cel puțin în parte mecanismele responsabile pentru disfuncția celulelor valvulare. În diabetul de tip 2, hiperglicemia se asociază de asemenea cu producția crescută de ROS și adeziunea monocitelor la endoteliu prin inhibarea producției de NO și creșterea nivelului de endotelină-1, E-selectină, ICAM-1 și VCAM-1. Monocitele ajunse în spațiul subendotelial se diferențiază în macrofage care secretă citokine proinflamatorii și înglobează LDL modificat, transformându-se apoi în celule spumoase (Manduteanu, Voinea et al. 1999, Nandy, Janardhanan et al. 2011, Padilla, Carpenter et al. 2018, Meza, La Favor et al. 2019). Inflamația precede calcificarea, iar în zonele calcificate din valvă au fost identificate celulele imune infiltrate. Se cunoaște că populația de macrofage din valvele calcificate este mai numeroasă decât cea din valvele normale și exprimă atât markeri caracteristici Mφ1, cât și Mφ2 (Li, Qiao et al. 2017).

În valvele stenotice provenite de la pacienți diabetici, exprimarea NF-κB și a FII și FXa în fibrosa este crescută față de valvele de la pacienți fără diabet. În plus, experimentele *in vitro* au confirmat că glucoza crescută provoacă inflamația VIC primare prin intermediul semnalizării mediate de NF-κB, ducând la calcificarea celulară (Kopytek, Mazur et al. 2021).

În valvele calcificate a fost evidențiată exprimarea redusă a VE-caderinei în fibrosa și a fost identificată în subendoteliu o populație de celule care co-exprimă α-SMA și CD31, dar nu și markerul hematopoietic CD45, sugerând ca aceste celulele provin din EndMT. Această populație celulară care prezintă și nivel crescut de NFκB nuclear a fost identificată doar în fibrosa, și se localizează distal față de zona calcificată (Mahler, Farrar et al. 2013). De asemenea, anterior s-a arătat că celulele endoteliale izolate din valvele calcificate sunt mai predispuse diferențierii osteogenice *in vitro* față de celulele endoteliale vasculare (Ma, Zhao et al. 2020). Se cunoaște că diabetul se asociază cu inflamația cronică, iar mediatorii pro-inflamatori TNF-α, IL-6, LPS, IFN-γ și TGF-β au fost implicați în activarea EndMT în VEC (Mahler, Farrar et al. 2013, Ma, Sanchez-Duffhues et al. 2020). *In vitro*, TNF-α și IL-6 au indus în celulele endoteliale valvulare aortice porcine (PAVEC) cultivate pe hidrogeluri 3D modificări asociate EndMT prin calea de semnalizare a factorului de transcripție NFκB: (1) scăderea exprimării CD31 și a VE-caderinei, (2) migrarea celulelor în matricea de colagen și (3) exprimarea de α-SMA (Mahler, Farrar et al. 2013).

Plasticitatea VIC și implicațiile pentru studiul BVA

MEC reglează fenotipul celulelor valvulare rezidente prin intermediul integrinelor, contribuie la menținerea tensiunii bazale celulare și oferă celulelor informații poziționale

(Santa-Cruz Mateos, Valencia-Exposito et al. 2020). De asemenea, MEC poate funcționa ca un rezervor de semnale biologice prin intermediul proteoglicanilor, care pot sechestra local molecule de semnalizare. Datorită rolului complex pe care MEC îl are în homeostazie, orice modificare la acest nivel poate conduce la patologie. *In vitro*, VIC tranziționează spontan în miofibroblaste (aVIC) și prezintă capacitate ridicată de contracție, atunci când sunt cultivate pe substrat rigid sau sunt stimulate cu citokine specifice (TGF-β), capacitate migratorie și proliferativă(Liu and Gotlieb 2008, Huang, Yang et al. 2012, Ma, Killaars et al. 2017). Studiile unde celulele valvulare au fost cultivate pe matrici tridimensionale de compoziție și rigiditate diversă, au evidențiat rolul semnificativ pe care substratul îl are în modularea fenotipului celular, cu implicații în patologia valvulară (Hutson, Marohl et al. 2016, Rutkovskiy, Malashicheva et al. 2017, Bogdanova, Zabirnyk et al. 2022). Plasticitatea VIC se păstrează deci și în cultură, astfel că una dintre cele mai mari probleme în studiul patologiei valvei aortice este lipsa unui model experimental *in vitro* care să replice cât mai apropiat compoziția și arhitectura țesutului valvular nativ.

În valva sănătoasă **tranziția qVIC în aVIC** reprezintă un proces implicat în menținerea arhitecturii valvei prin secreția componentelor MEC (colagen, fibronectină, condroitin sulfat, etc.) și de enzime care degradează aceste componente (MMP-uri, catepsine). Odată terminată remodelarea MEC, aVIC sunt eliminate prin apoptoză. În patologie, această semnalizare este însă afectată și aVIC continuă sinteza elementelor de MEC, cauzând fibrozarea țesutului și calcificarea distrofică. Atunci când devin activate, celulele interstițiale prezintă fibre de stres, exprimare crescută de α-SMA, miozina mușchiului neted, proteina specifică fibroblastelor (FSP-1) sau vimentină, dar și proteine ale MEC și citokine. Printre inductorii de activare a VIC se numără modificările asociate MEC, stresul mecanic sau TGF-β (Ma, Killaars et al. 2017, Goody, Hosen et al. 2020, Di Vito, Donato et al. 2021).

Tranziția qVIC în obVIC are loc în prezența de factori care promovează osteogeneza sau condrogeneza. obVIC sunt implicate activ în procesul de calcificare a valvei și sunt responsabile pentru stenoza târzie. În acest stadiu, comportamentul celular este guvernat de factorul de transcripție RUNX2 și de proteinele morfogenetice osoase (BMPs), iar obVIC secretă o serie de proteine exprimate în țesutul osos, precum osteopontină, osteocalcină și fosfatază alcalină (Yip, Chen et al. 2009). Rezultatele noastre recente au arătat că hiperglicemia induce supraexprimarea moleculelor osteogene BMP-2, BMP-4 și TGF-β în celulele valvulare aortice umane cultivate în modele 3D pe bază de gelatină metacrilată, cu efect asupra semnalizării SMAD1/5/8/9 și a exprimării factorului de

transcripție RUNX2, implicând astfel diabetul ca și contribuitor la calcificarea valvei aortice (Vadana, Cecoltan et al. 2020).

Studiul BVA in vivo și in vitro

Rolul celulelor valvulare în patologia valvei aortice în diabet încă nu este pe deplin elucidat și este studiat în prezent în mai multe tipuri de modele *in vivo* (Sider, Blaser et al. 2011, Puperi, Kishan et al. 2016, Jung, Ahmad et al. 2022) și *in vitro* (Hjortnaes, Goettsch et al. 2016, Porras, Westlund et al. 2018, Zabirnyk, Perez et al. 2020, Kruithof, van de Pol et al. 2021).

Patologia BVA în diabet este extrem de complexă, astfel că este necesar un **model *in vivo*** care să poată reda cât mai fidel ambele patologii. Modelele *in vivo* de diabet presupun utilizarea de animale cu predispoziție de a dezvolta diabet sau inducerea diabetului cu ajutorul agenților chimici (diabetogeni) care distrug celulele β-pancreatice. Cei mai utilizați agenți diabetogeni sunt streptozotocina și alloxan-ul, care sunt preluați în celulele β-pancreatice prin intermediul transportotului de glucoză GLUT2, unde generează ROS și radicali liberi, provocând fragmentarea ADN-ului și apoptoza celulelor.

În literatura de specialitate sunt descrise numeroase modele de diabet *in vivo*, dar pentru studiul BVA modelele curente prezintă limitări importante la nivel de recapitulare a caracteristicilor patologiei umane. De asemenea, modelele de BVA în diabet sunt și mai puține, iar fazele incipiente de apariție a leziunilor la nivelul VA au fost descrise majoritar *in vivo* la nivel ultrastructural (Filip, Nistor et al. 1987, Simionescu, Popov et al. 1996, Tucureanu, Filippi et al. 2019).

I*n vivo,* s-a arătat recent într-un model de șoarece dislipidemic predispus la dezvoltarea diabetului de tip 2 ($LDLr^{-/-}$/$ApoB^{100/100}$/IGF-II) că diabetul indus prin dietă provoacă mai rapid stenoza aortică (SA) și crește exprimarea la nivel de ARNm a genelor osteogenice față de șoarecii nediabetici ($LDLr^{-/-}$/$ApoB^{100/100}$) (Le Quang, Bouchareb et al. 2014). Similar, șoarecii $LDL^{r-/-}ApoB^{100/100}$ menținuți pe dietă diabetogenică/procalcifică timp de 12 luni prezintă depozite de calciu la nivelul VA și incidență de două ori mai mare a stenozei aortice confirmată prin modificarea parametrilor hemodinamici (Scatena, Jackson et al. 2018). Totuși, atunci cand diabetul este indus prin injectarea de streptozotocină într-un model de hamster hiperglicemic-hiperlipemic, rezultatele arată că valva aortică (VA) este primul teritoriu vascular afectat de diabet și hiperlipemie (HD), după doar 2 săptămâni de la inducerea diabetului. În valvele aortice de la hamsterii HD au fost identificate modificări ultrastructurale ale VEC (creșterea abundenței de organite biosecretorii, a microfilamentelor și microtubulilor) care s-au asociat cu hiperplazia membranei bazale la nivelul căreia au fost

identificate lipoproteine de joasă densitate (LDL) oxidate, sugerând că hiperglicemia induce în faza inițială disfuncția VEC (Simionescu, Popov et al. 1996).

In vitro, comportamentul celulelor interstițiale valvulare este influențat semnificativ atât de substratul pe care acestea sunt cultivate, cât și de arhitectura modelului de cultură. Culturile convenționale bi-dimensionale sunt cel mai puțin reprezentative pentru situația *in vivo,* dar sunt cel mai des utilizate pentru studiul VIC datorită ușurinței de stabilire a culturii. Studiile au arătat că, atunci când VIC sunt cultivate pe substrat rigid cum este polistirenul din plăcile de cultură, tranziționează spontan în miofibroblaste (Ma, Killaars et al. 2017). Deoarece a devenit evident rolul esențial pe care MEC îl are în reglarea funcției și disfuncției VIC (Gould, Matherly et al. 2014), un pas suplimentar față de cultura 2D a fost acoperirea suprafeței de cultură cu proteine ale MEC, iar acest tip de studii a furnizat informații importante legate de modul în care fenotipul VIC este reglat de substrat (Porras, van Engeland et al. 2017). Dintre toate elementele de matrice testate, acoperirea cu laminină a provocat agregarea VIC sub formă de noduli, iar colagenul de tip I a promovat un fenotip neactivat al VIC (Rodriguez and Masters 2009). Astfel, cercetările *in vitro* au continuat în ultimii ani cu tentative de a identifica un substrat tridimensional potrivit la nivel de compoziție sau arhitectură care să mențină fenotipul neactivat al VIC (qVIC), cu implementarea co-culturilor VIC-VEC și, nu în ultimul rând, cel mai recent, cu utilizarea de celule endoteliale valvulare umane.

Modelele 3D *in vitro* reprezintă o alternativă mai reprezentativă din punct de vedere al caracteristicilor structurale și funcționale ale mediului celular nativ, favorizând interacția cu celulele învecinate sau componentele MEC și ghidând comportamentul celular (Kaushik, Ponnusamy et al. 2018, Hong, Kim et al. 2019).

Modelele *in vitro* pentru studiul patologiei VA sunt realizate cu celule izolate de la pacienți sau provenite de la animale de mari dimensiuni care dezvoltă patologie similară cu cea umană, dintre care cele mai utilizate sunt cele porcine (Bowler and Merryman 2015). Deși sunt similare în multe privințe celulelor umane, celulele valvulare interstițiale porcine (PVIC) reprezintă totuși un model limitat *in vitro*, mai ales dacă sunt folosite la pasaje mari. Se cunoaște că atunci când sunt menținute în cultură pe termen lung, 20% dintre PVIC prezintă inhibiție de contact și au comportament instabil. De asemenea, potențialul de calcificare al PVIC scade după trei pasaje de la izolare (Chen, Yip et al. 2009). Pe de altă parte, utilizarea celulelor umane este limitată de disponibilitatea materialului biologic. Celulele umane sunt de cele mai multe ori extrase din probele de valve explantate de la pacienții cu stadii avansate de calcificare a valvei, iar celulele control sunt obținute doar de

la pacienții cu insuficiență aortică sau care suferă transplant de inimă (Goody, Hosen et al. 2020).

Un alt element esențial pentru replicarea condițiilor din VA *in vitro* este utilizarea unei co-culturi de VIC și VEC, pentru studiul interacției între cele 2 tipuri celulare. Numeroase studii au asociat cultivarea PVIC în prezența PVEC cu inhibarea tranziției lor în aPVIC sau obPVIC (Butcher and Nerem 2006, Kennedy, Hua et al. 2009, Richards, El-Hamamsy et al. 2013, Gould, Matherly et al. 2014). De asemenea, disfuncția sau denundarea endoteliului a fost semnalată drept eveniment de inițiere a transformării patologice a VIC (Hulin, Anstine et al. 2018, Hulin, Hego et al. 2018), făcând evident faptul că cele două populații celulare își reglează reciproc comportamentul.

Modele 3D obținute din țesuturi native

Multe dintre modelele 3D *in vitro* își au originea în ingineria tisulară, unde principalul obiectiv este acela de a dezvolta o variantă biologică de proteză a valvei. În acest scop, au fost testate din punctul de vedere al compatibilității cu celulele valvulare o varietate de metode și materiale sintetice sau naturale. Sistemele care mimează MEC nativă sunt de preferat, deoarece furnizează un mediu care replică arhitectura și condițiile din valvă (sechestrarea factorilor de creștere și a altor molecule, adeziunea celulară etc.) (Scott, Simon et al. 2021). Una dintre variantele utilizate cu succes pentru cultura tridimensională a celulelor *in vitro* sunt hidrogelurile obținute din polimeri naturali (colagen, gelatină) sau din țesuturi decelularizate. Țesuturile decelularizate pot la rândul lor să fie (1) repopulate cu celule, sau (2) procesate pentru obținerea hidrogelurilor din MEC nativă.

Hidrogelurile reprezintă rețele polimerice puternic hidratate care își păstrează integritatea structurală atunci când lanțurile polimerice, care pot fi de natură sintetică sau naturală, sunt polimerizate prin metode fizice sau chimice. Hidrogelurile sunt considerate analogul MEC native datorită proprietăților de a reține volume mari de fluide la interior, al elasticității, dar și a faptului că interfața dintre hidrogel și fluide se aseamănă cu cea observată în majoritatea țesuturilor moi (Geckil, Xu et al. 2010). Avantajele modelelor de cultură 3D au devenit evidente în ultimii ani, astfel că în prezent se încearcă dezvoltarea de hidrogeluri compatibile pentru cultura celulelor valvulare umane. În trecut, diferite proteine sau amestecuri proteice (Matrigel) prezente în matricea valvulară au fost utilizate pentru cultura celulelor valvulare, rezultatele fiind promițătoare. În prezent, utilizarea hidrogelurilor obținute din MEC nativă pentru studiul *in vitro* al BVA este încă foarte limitată. Rezultate promițătoare au fost obținute în cazul unui hidrogel produs din valve aortice ovine decelularizate, care păstrează o componență proteică similară cu cea din valva

nativă (colagen și laminină), dar un conținut relativ scăzut de GAG. Acest hidrogel a prezentat biocompatibilitate similară cu suporturile pe bază de colagen I la nivel de proliferare celulară și nu a avut efect citotoxic asupra VIC (Nehrenheim, Raschke et al. 2019).

Polimerii naturali precum agaroza, alginatul, colagenul, fibrina, gelatina, chitosan-ul sau acidul hialuronic pot fi de asemenea utilizați pentru obținerea de hidrogeluri și generarea de suporturi biologice. Datorită faptului că reprezintă componenta majoritară a MEC din valvă, colagenul de tip I a fost printre primele materiale utilizate pentru cultura tridimensională *in vitro* a celulelor valvulare, iar VIC crescute în geluri de colagen 2% au prezentat un fenotip mai puțin activat (Cushing, Mariner et al. 2008). În ciuda avantajelor de natură biologică ale colagenului, acest material prezintă și o serie de limitări, precum faptul că VIC contractă aceste matrici. Din aceste motive, gelatina modificată reprezintă o alternativă a utilizării colagenului. Gelatină metacrilată (GelMA) permite obținerea de hidrogeluri cu rigiditate ușor de ajustat, care favorizează adeziunea celulară și pot fi combinate ușor cu alte tipuri de materiale. Hidrogelurile de GelMA au fost utilizate cu succes pentru cultura de PVIC sau co-cultura VIC-VEC porcine în sisteme de tipul ”organ-on-a-chip” (Chen, Srigunapalan et al. 2013). Pentru obținerea de modele mai complexe, se utilizează frecvent combinația GelMA cu alte proteine ale MEC specifice VA, precum acidul hialuronic (AH).

La nivel internațional, cercetarea din domeniu se concentrează în principal pe: (1) îmbunătățirea înțelegerii proceselor biologice de bază asociate patologiei valvei aortice, inclusiv căile de semnalizare implicate și rolul inflamației în inițierea și propagarea bolii; (2) determinarea contribuțiilor unice asociate comorbidităților în BVA (3) dezvoltarea unor metode de imagistică pentru identificarea manifestărilor subclinice asociate BVA și (4) investigarea fezabilității unei intervenții farmacologice în stadiile inițiale ale BVA(Rajamannan, Evans et al. 2011).

Analiza prezentată în Partea I “Stadiul actual al cunoașterii” scoate în evidență trei probleme deosebit de importante, și anume: (1) BVA este accelerată în diabet prin mecanisme care nu au fost încă descrise, (2) modificarile moleculare din stadiile inițiale ale BVA în diabet nu au fost abordate în modelele *in vivo* și (3) modelele 3D *in vitro* existente nu includ celule valvulare umane si comunicarea dintre ele, esentiale pentru reproducerea mediului din VA nativă.

În acest context, **ipoteza** de la care a plecat prezenta această cercetare este că hiperglicemia asociată diabetului induce modificări specifice în procesul inflamator din

valva aortică, contribuind la inițierea și progresia accelerată a BVA. Astfel, obiectivul principal al studiului a fost investigarea mecanismelor prin care hiperglicemia induce și propagă inflamația celulelor valvulare aortice.

În acest sens, au fost stabilite următoarele **obiective științifice**:

1. Caracterizarea procesului inflamator în valva aortică asociat diabetului timpuriu într-un model *in vivo* de soarece diabetic, hiperlipemic;
2. Dezvoltarea de modele 3D *in vitro* populate cu celule valvulare umane și utilizarea lor pentru investigarea mecanismelor implicate în inflamația celulelor valvulare în condiții de expunere la concentrații crescute de glucoză..

Astfel, **a doua parte a tezei** constă în Contribuțiile originale aduse în vederea îndeplinirii acestor obiective, și este împărțită în două capitole.

Capitolul I a avut ca obiectiv principal investigarea mediatorilor inflamației în diabetul timpuriu în valva aortică într-un model *in vivo* de șoarece diabetic, hiperlipemic. În acest scop, au fost utilizați șoareci C57BL/6J masculi, ApoE $^{-/-}$, cărora le-a fost indus diabet de tip I prin injectarea de streptozotocină (STZ), și șoareci control (C), injectați doar cu soluție vehicul de tampon citrat. Încă din ziua 4, la nivelul VA murine au fost evidențiate leziuni cu infiltrate lipidice caracteristice etapelor timpurii ale bolii valvulare, prin colorații histologice ale lipidelor, colagenului și GAG. Analiza de imunofluorescență a arătat o creștere foarte rapidă, din ziua a 4-a, a exprimării moleculelor de adeziune P-selectină, VCAM-1, ICAM-1 și PECAM-1 la șoarecii din grupa STZ4, care s-au păstrat cel puțin la fel de ridicate în ziua 7 de la inducerea diabetului în grupa STZ7. De asemenea, markerii mezenchimali, α-SMA și FSP-1, au crescut semnificativ la șoarecii STZ4 și STZ7 față de controalele C4 și C7, sugerând rolul diabetului în activarea celulelor valvulare. Vimentina, un alt marker al celulelor mezenchimale a fost identificată ca fiind crescută semnificativ la grupele experimentale de 7 zile (C7 și STZ7) față de 4 zile, implicând dieta bogată în lipide în tranziția celulelor valvulare către fenotipuri mezenchimale.

La nivelul valvelor provenite de la șoarecii diabetici au fost identificate prin imunohistochimie celule implicate în EndMT în zona leziunilor bogate în lipide, sugerând că diabetul este implicat în supraexprimarea markerilor de disfuncție ai celulelor valvulare aortice. Mediatorii inflamatori modificați în diabet au fost utilizați pentru generarea unei matrici de corelații împreună cu proteinele implicate în remodelarea și calcificarea valvei în diabet identificate, dar și cu parametrii plasmatici și funcționali asociați stării diabetice (Tucureanu, Filippi et al. 2019, Vadana, Cecoltan et al. 2020). Corelații semnificative au fost identificate între mediatorii inflamatori, osteogeni și de remodelare și parametrii plasmatici,

sugerând asociații moleculare specifice care pot contribui la disfuncția timpurie a valvei, detectată în modelul de șoarece diabetic hiperlipemic.

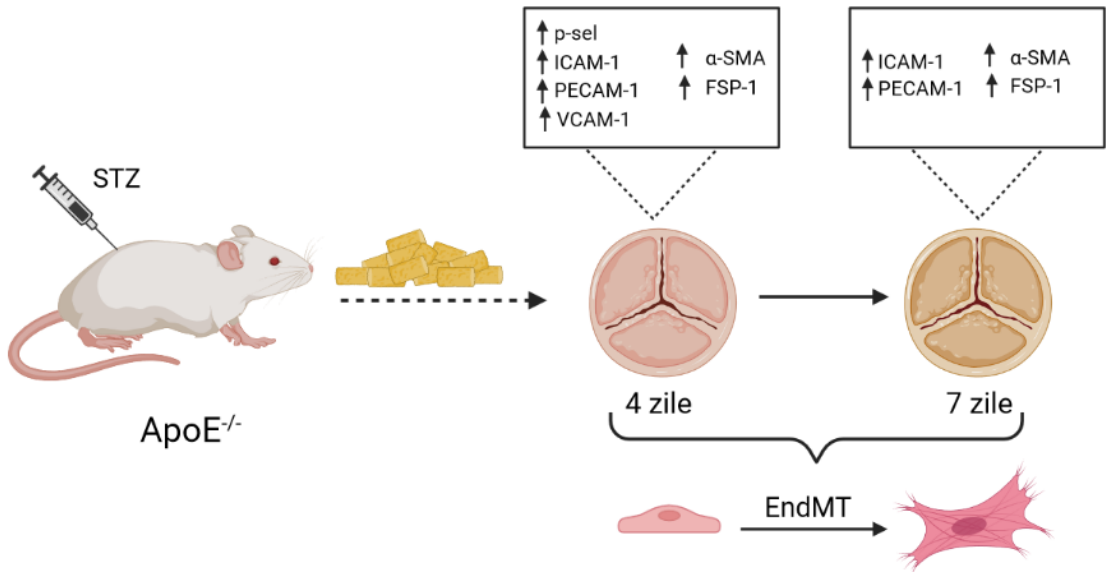

Figura 1. Schematizarea concluziilor studiului in vivo. *Șoarecii ApoE$^{-/-}$ injectați cu STZ și hrăniți cu dietă bogată în lipide prezintă supraexprimarea markerilor de activare a VEC (P-selectina, VCAM-1, ICAM-1si PECAM-1) și de activare a VIC (α-SMA și FSP-1) la 4 și 7 zile și celule implicate în EndMT.*

La nivelul valvelor provenite de la șoarecii diabetici au fost identificate prin imunohistochimie celule implicate în EndMT în zona leziunilor bogate în lipide, sugerând că diabetul este implicat în supraexprimarea markerilor de disfuncție ai celulelor valvulare aortice. Mediatorii inflamatori modificați în diabet au fost utilizați pentru generarea unei matrici de corelații împreună cu proteinele implicate în remodelarea și calcificarea valvei în diabet identificate, dar și cu parametrii plasmatici și funcționali asociați stării diabetice (Tucureanu, Filippi et al. 2019, Vadana, Cecoltan et al. 2020). Corelații semnificative au fost identificate între mediatorii inflamatori, osteogeni și de remodelare și parametrii plasmatici, sugerând asociații moleculare specifice care pot contribui la disfuncția timpurie a valvei, detectată în modelul de șoarece diabetic hiperlipemic.

Cercetarea din **Capitolul II** a vizat investigarea *in vitro* a mecanismelor implicate în inflamația celulelor valvulare în condiții de expunere cronică la concentrații crescute de glucoză, și a avut **trei obiective specifice**: (1) izolarea și caracterizarea de celule valvulare aortice umane primare (2) dezvoltarea de modele 3D *in vitro* populate cu celule valvulare

umane și (3) descrierea mecanismelor implicate în inflamația celulelor valvulare în condiții de expunere cronică la concentrații crescute de glucoză în modelele 3D dezvoltate.

Pentru îndeplinirea **obiectivului specific (1)**, celulele valvulare umane au fost izolate prin digestie enzimatică din valve aortice umane obținute de la Spitalul Militar Central (București) în urma operațiilor de înlocuire a valvei. Culturile pure de celule valvulare endoteliale si interstitiale primare au fost stabilite prin separarea cu sfere magnetice CD31+, iar markerii specifici VIC și VEC au fost puși în evidență prin imunohistochimie.

În cadrul **obiectivului (2)** au fost investigate mai multe variante de modele *in vitro*: cuspă porcină decelularizată repopulată cu celule umane (subcapitolul II.1.2.), model bioprintat pe bază de hidrogeluri comerciale (subcapitolul II.1.3.) și modele pe bază de hidrogeluri dezvoltate în cadrul laboratorului nostru din gelatină metacrilată (subcapitolul II.1.4.) și din rădăcină aortică porcină decelularizată (subcapitolul II.1.5.).

Modelul de cuspă porcină decelularizată și repopulată cu celule umane (subcapitolul II.1.2.) a presupus 2 etape: (1) decelularizarea țesutului nativ și (2) repopularea matricei obținute cu celule umane. Pentru prima etapă, decelularizarea a fost confirmată prin cuantificarea ADN-ului din matricea rezultată și colorații histologice pentru evidențierea celulelor și a proteinelor de MEC. Pentru a doua parte, au fost testate multiple tehnici pentru repopularea matricei cu celule umane. La exterior s-a reușit obținerea unui monostrat uniform de celule endoteliale, dar randamentul de repopulare a matricei la interior cu fibroblaste/VIC nu a fost suficient de ridicat pentru realizarea unui model *in vitro* pentru investigarea patologiei valvei aortice.

Dintre formulele de hidrogeluri comerciale testate pentru obținerea unui model bioprintat *in vitro* (subcapitolul II.1.3.), hidrogelurile pe bază de gelatină au prezentat compatibilitate cu celulele confirmată prin teste de viabilitate și microscopie. VIC încapsulate în hidrogelurile BioInk și Gel4Cell au prezentat viabilitate ridicată și au format o rețea tridimensională la interiorul construcților 3D. Pe de altă parte, VEC nu sunt compatibile cu tipul de cultură încapsulată, dar atunci când sunt cultivate deasupra hidrogelurilor pe bază de gelatină proliferează și formează monostrat caracteristic. Dintre cele 3 formule testate, hidrogelurile pe bază de gelatină care au prezentat cea mai ridicată biocompatibilitate, au fost și cel mai greu de bioprintat datorită proprietăților variabile și a instabilității în cultură la 37°C. Formula CellinkRGDa fost cea mai compatibilă cu protocolul de bioprintare, dar nu și cu cu celulele valvulare umane.

Plecând de la rezultatele promițătoare de biocompatibilitate cu celulele valvulare ale hidrogelurilor comerciale pe bază de gelatină și a informațiilor din literatura de specialitate,

în umătoarea parte a cercetării (subcapitolul II.1.4.) am dezvoltat în cadrul laboratorului nostru o formulă de hidrogel pe bază de gelatină metacrilată (GP-1). Rezultatele de biocompatibilitate și caracterizare fenotipică au arătat că hidrogelul GP-1 dezvoltat în laborator nu este citotoxic, permite proliferarea celulară, iar celulele valvulare încapsulate în hidrogel sau cultivate la suprafața lui își păstrează markerii caracteristici. De asemenea, exprimarea genică la nivel de ARNm determinată prin RT-PCR și proteică determinată prin Westrn Blot a α-SMA, marker de activare a VIC, scade atunci când celulele sunt cultivate în hidrogelul GP-1 față de cultura 2D clasică, replicând fenotipul VIC caracteristic valvei native. Exprimarea genică crescută la nivel de ARNm a α-SMA din prima săptămână este comparativă cu cea din cultura 2D, și se asociază cu exprimarea crescută a MMP-urilor și a unor elemente de MEC (colagen I, colagen III, elastină și laminină), sugerând un proces inițial de remodelare și adaptare a celulelor în noua matrice (Ciortan, Macarie et al. 2020).

Pentru obținerea unui model cu structură proteică mai apropiată de cea a MEC din VA nativă, am dezvoltat o a doua formulă de hidrogel din matrice extracelulară nativă porcină (HDRA). La fel ca și în cazul primelor studii, hidrogelul a fost evaluat din punct de vedere al compoziției proteice, prin colorații histologice și SDS-PAGE. Astfel, s-a arătat că principala componentă din HDRA este colagenuul de tip I și/sau III, asemănătoare stratului fibrosa din valvă. Analiza histologică a arătat că structura construcților pe bază de HDRA este foarte similară din punct de vedere al densității și porozității cu cea a țesutului valvular nativ decelularizat. Din analiza de biocompatibilitate cu celulele valvulare umane realizată prin imunohistochimie și determinarea viabilității, a rezultat că VEC formează un monostrat continuu la suprafața construcților HDRA, exprimă markerul endotelial CD31 și proliferează în cultură, iar VIC se distribuie uniform în interiorul hidrogelului unde formează o rețea complexă.

Pentru îndeplinirea **obiectivului (3)** modelele *in vitro* pe bază de hidrogel din gelatină metacrilată (GP-1) și hidrogel din rădăcină aortică porcină decelularizată (HDRA) dezvoltate în cadrul laboratorului nostru au fost utilizate pentru a investiga inflamația celulelor valvulare aortice umane în condiții de expunere la cronică la concentrații crescute de glucoză.

În **modelul *in vitro* bazat pe hidrogel GP-1** și populat cu celule valvulare umane în co-cultură, rezultatele de RT-PCR au arătat că, atunci când sunt expuse la concentrații crescute de glucoză (HG), VEC devin disfuncționale prin supraexprimarea la nivel de ARNm de citokine și chemokine cu efect pro-inflamator (MCP-1, TNF-α și IL-8 la 7 zile și MCP-1 și IL-1β la 14 zile de HG) și molecule de adeziune (VCAM-1 și E-selectină la 7 și

14 zile de HG). În contrast, expunerea la HG până la 14 zile nu modifică exprimarea α-SMA în VIC, sugerând că glucoza nu este implicată în tranziția VIC către un fenotip activat de tip miofibroblast. VIC răspund însă la concentrația crescută de glucoză prin asumarea unui fenotip inflamator, caracterizat prin creșterea exprimării de citokine și chemokine cu efect pro-inflamator, la 7 (IL-1β) și 14 zile (TNF-α, IL-8 și IL-1β) de expunere la HG. Activarea VEC are deci loc în principal în ziua 7 de expunere la HG, după care este posibil să se propage la VIC în ziua 14. Expresia proteică a mediatorilor inflamatori IL-1β și MCP-1 secretați în mediu de celulele valvulare cultivate în HG determinată prin ELISA crește semnificativ doar în ziua 14, confirmând astfel că inflamația celulelor valvulare este mai pronunțată la un timp experimental mai lung..

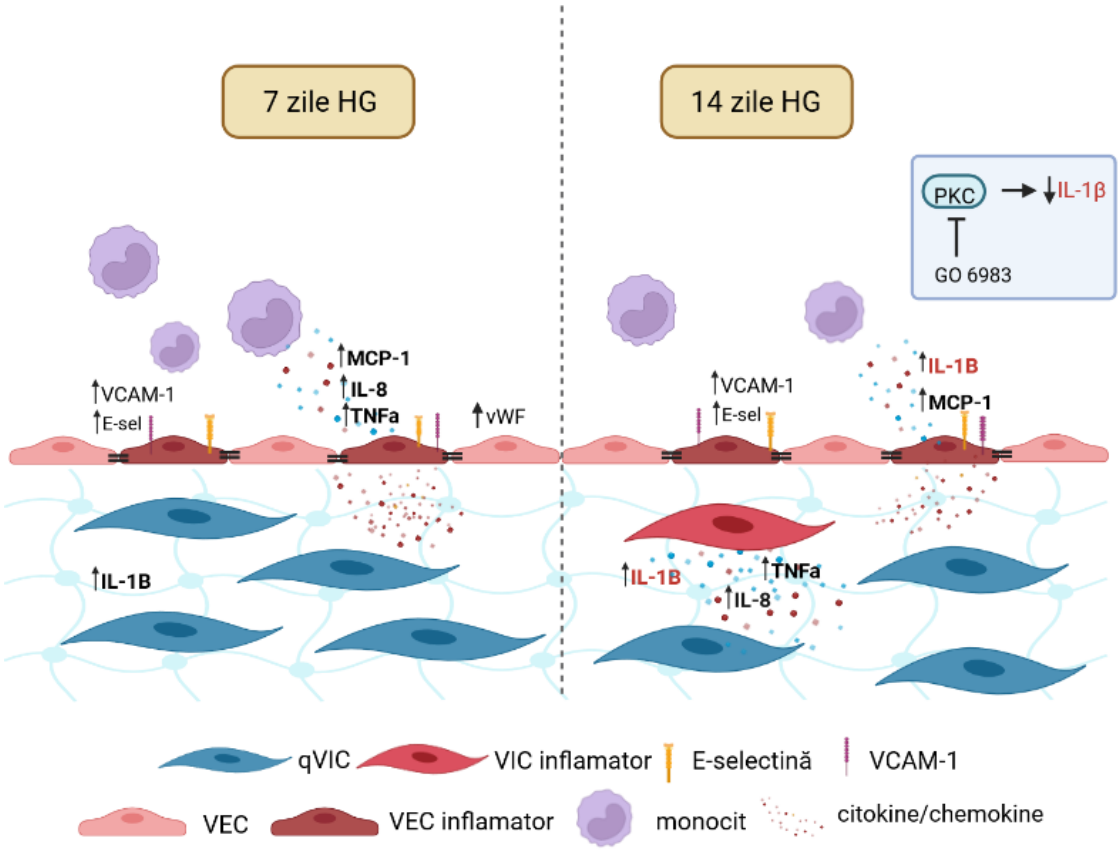

Figura 2. Schematizarea concluziilor studiului pe modelul in vitro GP-1*. Expunerea cronică la HG induce un răspuns inflamator secvențial al celulelor valvulare: la 7 zile răspunsul inflamator al VEC este cel dominant, și se caracterizează prin supraexprimarea vWF, MCP-1, IL-1β , VCAM-1 și E-selectină. La 14 zile VIC tranziționează către un fenotip inflamator puternic (supraxexprimarea IL-1β, TNF-α, IL-8), sugerând că inflamația cronică a VIC se poate datora în parte VEC, instalându-se deci mai târziu în timpul progresiei BVA;*

Un potențial mecanism implicat în exprimarea și eliberarea IL-1β în condiții de expunere cronică la concentrații crescute de glucoză este mediat de calea PKC.

La nivel molecular, utilizând modelul de co-cultură în hidrogel GP-1, am identificat un potențial mecanism de exprimare a IL-1β în condiții de expunere cronică la glucoză crescută, intermediat de pPKC. Astfel, am observat că exprimarea pPKC crește semnificativ în VEC la 7 zile și în VIC la 14 zile în condiții de HG, iar inhibarea ei reduce semnificativ concentrația de Il-1β secretat în mediu în condiții de HG. Astfel, rezultatele obținute în modelul GP-1 sugerează că, în condiții de HG, procesul inflamator la nivelul valvei este declanșat întâi de VEC, după care se propagă la VIC, unde inflamația se cronicizează și poate favoriza calcificarea valvei.

În **modelul *in vivo* bazat pe hidrogel HDRA** au fost investigate în principal modificările fenotipice ale VEC cu implicații în patologia valvulară. Rezultatele de exprimare genică și imunohistochimie au arătat că, atunci când construcții HDRA populați cu celule valvulare umane sunt expuși unor concentrații patologice de glucoză, are loc declanșarea EndMT, observată și in modelul *in vivo*, caracterizată prin supraexprimarea markerilor mezenchimali (α-SMA și vimentină), scăderea exprimării markerilor endoteliali (CD31 și VE-caderină) și creșterea co-localizării α-SMA și CD31 în celulele valvulare. Se poate concluziona astfel că o concentrație patologică de glucoză, similară celei din diabet, favorizează EndMT, posibil prin crearea unui mediu pro-inflamator în valvă, așa cum am arătat că se întâmplă în construcții GP-1. Anterior, Mahler și colab. (2013) au demonstrat că citokinele inflamatorii (TNFα și IL-6) induc EndMT în celulele endoteliale valvulare ovine, proces prin care sunt generate miofibroblaste implicate în remodelarea patologică a valvei (Mahler, Farrar et al. 2013).

O altă moleculă a cărei exprimare crescută se asociază cu disfuncția VEC și care a fost identificată drept agent proinflamator în diabetul timpuriu este ET-1 (Iglarz and Clozel 2007, Saleh, Boesen et al. 2011). Importanța ET-1 în diabet a fost evidențiată prin studii care au arătat că HG crește exprimarea ET-1 în celulele primare și liniile de celule endoteliale aortice și că dereglarea sistemului ET-1 joacă un rol important în instalarea și progresia patologiei macro- și microvasculaturii în diabet (Pernow, Shemyakin et al. 2012, Manea, Todirita et al. 2013). A fost arătat că ET-1 și receptorii săi sunt supraexprimați în stenoza aortică, sugerând că o serie de modificări patologice asociate leziunilor aterosclerotice și calcificării valvei pot fi o consecință a semnalizării ET-1(Peltonen, Taskinen et al. 2009). Din aceste motive, am investigat efectul HG asupra exprimării ET-1 în VEC cultivate în

HDRA. Rezultatele de RT-PCR au arătat că exprimarea ET-1 și a receptorilor săi (ET-A și ET-B) este crescută în VEC din construcții HDRA expuși 7 zile la HG față de martorul de glucoză normală (NG). În plus, rezultatele ELISA arată că nivelul de IL-1β și MCP-1 din mediul de cultură al construcților expuși la HG este redus semnificativ atunci când construcții sunt expuși la HG în prezența de antagoniști ai receptorilor ET-1. Antagonistul receptorului de tip B reduce secreția de citokine și chemokine pro-inflamatorii aproape de nivelul observant la martorul NG, demonstrând astfel implicarea semnalizării ET-1 în inflamația VEC initiată de HG. Deoarece se cunoaște că IL-1β este implicată în tranziția fenotipică a celulelor endoteliale vasculare din cadrul EndMT, se poate presupune că IL-1β ar putea fi implicat în EndMT în celulele endoteliale valvulare. A fost demonstrat anterior că atât ET-1 cât și IL-1β sunt implicate în inducerea EndMT în celulele endoteliale din alte paturi vasculare (Chaudhuri, Zhou et al. 2007, Widyantoro, Emoto et al. 2010). Rolul ET-1 în EndMT a fost studiat *in vivo* în șoareci diabetici deficienți pentru gena care codifică proteina ET-1, unde s-a arătat că ET-1 promovează dezvoltarea fibrozei cardiace (Cho, Lee et al. 2018).

Expunerea VEC cultivate pe HDRA la glucoză crescută a dus de asemenea la supraexprimarea moleculelor de adeziune ICAM-1 și VCAM-1 implicate în recrutarea de monocite în spațiul subendotelial.

Datele obținute pe modelul HDRA sugerează că glucoza crescută promovează EndMT a VEC, posibil prin semnalizarea ET-1 și secreția de IL-1β. De asemenea, mediul inflamator creat poate contribui la creșterea aderenței endoteliului pentru celule imune și și propagarea inflamației în valvă.

Studiile prezentate în cadrul tezei referitoare la procesul inflamator în condiții de diabet, împreună cu cele realizate în cadrul grupului nostru de cercetare (Tucureanu, Filippi et al. 2019) referitoare la markerii de calcificare, au arătat că procesul inflamator și tranziția osteogenică a celulelor interstitiale valvulare au loc concomitent în diabetul timpuriu, cu implicații asupra disfuncției valvei. Până în prezent, efectelul hiperglicemiei asupra celulelor valvulare umane cultivate în modele 3D *in vitro* nu a fost investigat de niciun alt grup, astfel că rezultatele obținute în această cercetare sunt originale.

Obținerea acestor rezultate a fost posibila prin utilizarea tehnicilor de lucru cu animale pentru stabilirea modelului *in vivo,* decelularizarea țesuturilor și dezvoltarea de hidrogeluri pentru obținerea modelelor *in vitro*, utilizarea tehnicilor de biologie moleculară, imunohistochimie sau adeziune în flux, ceea ce subliniază caracterul interdisciplinar și complexitatea cercetării prezentate.

Una dintre limitările acestei cercetări constă din utilizarea unui model murin de diabet, care nu replică foarte exact patologia umană. Deși există avantaje experimentale certe și se pot obține date importante despre patofiziogia diabetului, se cunoaște că diabetul dezvoltat în modelele animale nu este echivalent cu diabetul uman, astfel că este necesară precauție în interpretarea rezultatelor și extrapolarea lor la patologia umană. În cazul modelelor *in vitro*, o limitare constă din lipsa caracterizării hidrogelurilor dezvoltate în cadrul laboratorului nostru din punct de vedere al proprietăților fizice relevante pentru cultura de celule *in vitro* (rigiditate, viteză de degradare, vâscozitate), datorată lipsei unei infrastructuri adecvate pentru o astfel de analiză. Din acest motiv, în vederea îmbunătățirii formulelor de hidrogel GP-1 și HDRA pentru extinderea studiilor prezentate în această cercetare, îmi propun să colaborez pe viitor cu o unitate de cercetare care să realizeze astfel de analize.

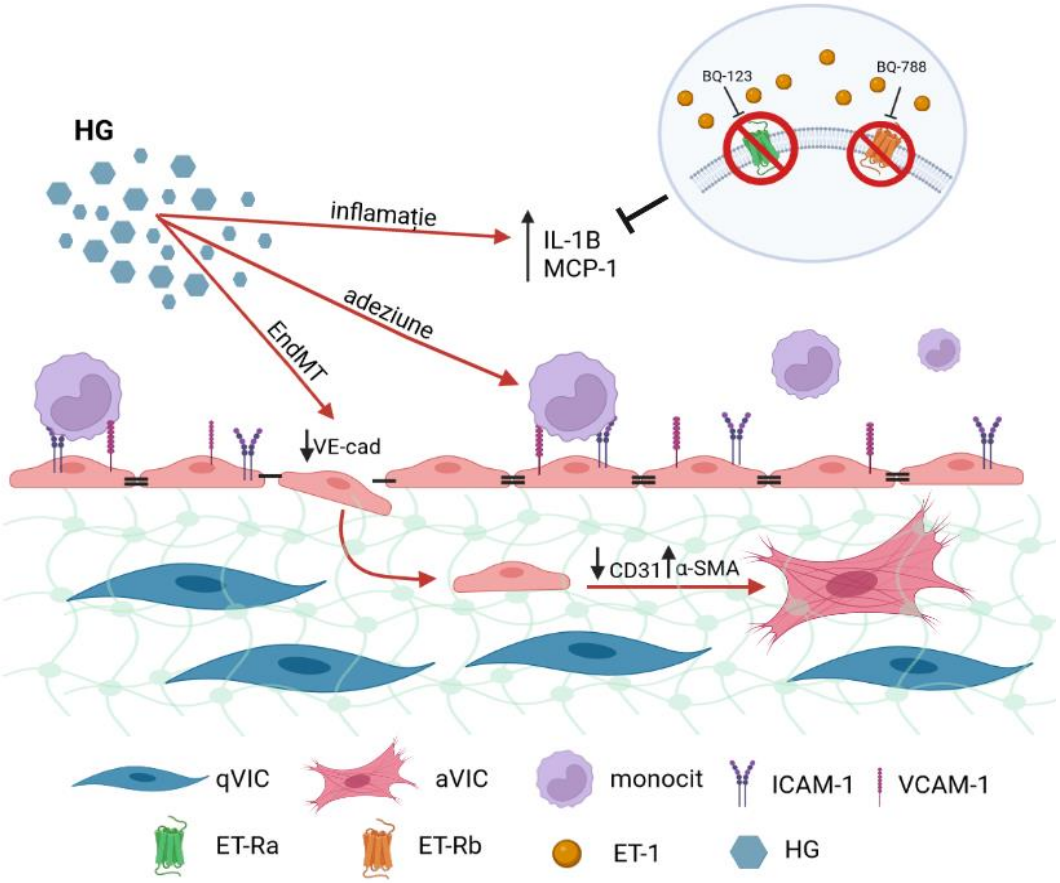

Figura 3. Schematizarea concluziilor studiului pe modelul in vitro HDRA. *Expunerea cronică la oncentrație crescută de glucoză favorizează (1) inițierea procesului de EndMT, caracterizată prin scăderea exprimării markerilor endoteliali (CD31 și VE-caderină), supraexprimarea markerilor mezenchimali (α-SMA și vimentină) și creșterea co-localizării*

α-SMA și CD31 în celulele valvulare; (2) recrutarea monocitelor prin supraexprimarea moleculelor de adeziune VCAM-1 și ICAM-1 la niveleul VEC și (3) exprimarea și eliberarea de citokine și chemokine pro-inflamatorii IL-1β și MCP-1, prin mecanisme mediate în parte de ET-1 și receptorii săi ET-Ra și ET-Rb.

Complexitatea și dezvoltarea lentă a BVA în timp pot fi considerate o oportunitate în ceea ce privește posibilitatea de a planifica intervenții terapeutice înainte ca intervenția chirurgicală să devină inevitabilă. Astfel, identificarea principalelor molecule asociate procesului inflamator indus de diabet celulelor valvulare și descrise în acest studiu are ca perspective în primul rând definirea unor abordări terapeutice țintite, specifice, care în prezent nu sunt disponibile. De altfel, molecula de adeziune VCAM-1, găsită ca fiind supraexprimată de endoteliul valvular în studiile din teza de față, a fost deja utilizată cu succes drept țintă pentru oprirea tranziției osteogene a VIC. Astfel, țintirea cu Runx2-shRNA *in vitro* a redus nivelul de Runx2, OSP, BSP, BMP-2 (Voicu, Rebleanu et al. 2022), iar rezultatele preliminare *in vivo* sunt promițătoare. Mai mult, hidrogelurile și modelele 3D dezvoltate în acest studiu pot reprezenta un punct de plecare pentru dezvoltarea unui model bio-printat de foiță valvulară populată cu celule umane, care să reprezinte o platformă de testare a terapiilor farmacologice pentru tratamentul BVA.

Content:

INTRODUCTION *10*

FIRST PART – ACTUAL STATE OF KNOWLEDGE REGARDING LIPID RAFTS AND SIGNALING MOLECULAR MECHANISMS *11*

I.1. Introductory notions *11*

I.2. The cell membrane as a basis for the organization of membrane microdomains *14*

I.2.1 Lipids as part of cell membranes and membrane microdomains *14*

I.2.2 Lipid bilayer and membrane asymmetry *16*

I.2.3 Sterols and cholesterol - major constituents of membrane microdomains *19*

I.3. The concept of lipid rafts (membrane microdomains) *21*

I.4. The dynamics of plasma membrane molecules and membrane microdomains *36*

I.4.1 Biochemical and biophysical methods to investigate the dynamics of lipid rafts *38*

I.4.2 Lipid rafts stability generated by the relationship between the size and life time *41*

I.4.3 Modeling and destabilizing lipid rafts *45*

I.5. Dynamic functionality of lipid rafts determined by external, membrane and cytosolicfactors *49*

I.5.1 External factors that control the dynamics of lipid rafts *50*

I.5.2 Lipid rafts dynamics control at the plasma membrane level *52*

I.5.3 Internal cell factors that control the dynamics of lipid rafts *57*

I.6. Lipid rafts as signaling platforms *59*

I.6.1 Signaling platform generation through lipid rafts *64*

I.7. Lipid raft dependent endocytosis *68*

I.7.1 Dynamin dependent non-caveolae endocytosis *74*

I.7.3 Lipid raft dependent endocytosis regulation. Cav1 negative regulation. Cholesterol and actin cytoskeleton role in lipid raft mediated endocytosis *76*

I.7.4 Lipid raft endocytosis and the modulation of signaling cascades *79*

I.8. Plasma membrane microdomains dependent apoptotic function *81*

I.8.1 Membrane receptors and channels apoptosis *84*

I.8.1.1 Fas *84*

I.8.1.2 CD5 ..... *85*

I.8.1.3 CD20 ..... *86*

I.8.1.4 Trpc-1 ..... *86*

I.8.2 Lipid rafts in protein kinase induced apoptosis *87*

I.8.2.1 Akt *87*

I.8.2.2 JNK *88*

I.8.2.3 Src kinase family *89*

I.8.2.4 PKC protein family *89*

I.9. Lipid raft atherogenesis and signaling mechanisms *91*

I.9.1 Transendothelial transport of low-density lipoproteins 93

I.9.1.1 The hyperlipidemic excess as stress factor in the atherogenic process induces changes in lipid raft composition 93

I.9.1.2 High density lipoproteins and statin action mechanisms and implications over the structure (composition) of lipid rafts 98

I.9.2 The inflammatory process promoted by lipid rafts 101

I.9.3 Lipid raft associated protease activity 102

I.9.4 Lipid rafts in smooth muscle cell proliferationand atherosclerosis 104

SECOND PART – ORIGINAL CONTRIBUTIONS *105*

II.1. Introduction and objectives *105*

II.2 Experimental methodology *110*

II.2.1 Reagents 110

II.2.2 Experimental animal models 111

II.2.2.1 Hamsters 111

II.2.2.2 Mice 112

II.2.3 Optical microscopy performed on cryosections 112

II.2.4 ELISA technique 113

II.2.5 Lipid raft extraction by sucrose gradient ultracentrifugation 113

II.2.6 Single dimension electrophoresis and Western blotting 114

II.2.7. 2 Dimensional differential electrophoresis (2D-DIGE) 115

II.2.8 High performance liquid chromatography mass spectrometry.MALDI-TOF mass spectrometry 122

II.2.8.1 Sample preparation for LC-MS/MS analysis 132

II.2.8.2 Liquid nano-chromatography peptide separation 133

II.2.8.3 Mass spectrometric analysis (LC-MS and MALDI-TOF) 134

II.2.8.4 LC-MS data analysis for protein identification 134

II.2.8.5 LC-MS data analysis for protein quantification 135

II.2.8.6 Identification of representative signaling pathways 137

II.2.8.7 MALDI-TOF analysis 138

II.2.9 Statistical analysis 139

II.3 Results. Experimental studies and bioinformatics *140*

II.3.1 Experimantal animal models characterisation and validation *140*

II.3.1.1 ApoE deficient mice 140

II.3.1.2 Hyperlipidemic hamsters. 142

II.3.2 Hamsters and mice isolated DRM characterisation *144*

II.3.2.1 Discussions and conlusions 151

II.3.3 2D-DIGE experimental methodology revealed substantial modifications of hyperlipidemic hamsters DRM protein profiles *154*

II.3.3.1 MALDI-TOF protein spots analysis revealed that the hyperlipidemic condition and the statin treatment significantly modified the expression of some structural and signaling molecules *163*
II.3.3.2 Discussions and conlusions *167*

II.3.4 Differential proteomic analysis of actin dependent signaling pathways of ApoE defficient mice isolaed membrane microdomains *169*

II.3.4.1 Shotgun proteomic analysis *169*
II.3.4.2 DRM proteins relative quantification *172*
II.3.4.3 Actin dependent signaling pathways DRM protein expression analysis *174*
II.3.4.4 Discussions and conlusions *180*

II.3.5 DRM resident and associated protein expression modification. Mass spectrometric analysis demonstrates Hsp regulation by the DRMs *186*

II.3.5.1 The hyperlipidemic condition induces the over-expression of caveolin-1 in DRMs *186*
II.3.5.2 The hyperlipidemic condition induces the under-expression of PTRF in DRMs *187*
II.3.5.2 The expression analysis of some Caveolin-1 co-fractionated proteins (filamin A, dynamin) *188*
II.3.5.3 The analysis of serum released and DRM localised heat shock proteins *189*
II.3.5.4 Discussions and conlusions *191*

II.3.6 The comparative proteomic analysis of DRMs isolated from two hyperlipidemic experimental models *195*

II.3.6.1 Qualitative mass spectrometric analysis *195*
II.3.6.2 DRM proteins relative quantification *201*
II.3.6.3 The analysis of Mus Musculus și Mesocricetus Auratus differentially expressed proteins implicated in common signaling pathways *205*
II.3.6.4 The signaling pathways analysis of Mus Musculus differentially expressed proteins *214*
II.3.6.5 The signaling pathways analysis of Mescocricetus Auratus differentially expressed proteins *218*
II.3.6.6 Discussions and conlusions *220*

INTRODUCTION

Atherosclerosis is a disease mainly of the large and medium caliber arteries with severe clinical manifestations (atherosclerotic plaque) and often with tragic end (cardiac ischemia, lower limb gangrene, ischemic encephalopathy, myocardial infarction, cerebral infarction). Hyperlipidemia is a major risk factor in atherosclerosis, statin treatment being the most common measure to counteract the increased circulating lipid levels. The endothelial cells are the first to come into contact and are activated by pro-atherogenic factors, such as elevated levels of cholesterol and triglycerides in the circulating lipoproteins, which results in endothelial dysfunction. Pulmonary endothelium is directly involved in a number of vital functions of the body (solute exchange, regulation of vascular tone, vasculogenesis, angiogenesis) and although it does not normally develop atherosclerotic plaques, it can be activated by pro-atherogenicstress factors, (hyperlipidemicdiet, hypertension, deregulated production of nitric oxide, etc.) with implications in altering signaling pathways in the atherosclerotic plaques prone areas.

Studies have shown the importance of signaling mechanisms in the biological membranes, these structural and functional barriers actively involved in cell homeostasis. Membrane microdomains represent dynamic membrane nano-assemblies with a special protein and lipid content involved in transport, cholesterol homeostasis, etc. This particular structure determines their characteristic of being insoluble in non-ionic detergents and flotation in a density gradient following ultracentrifugation at 200000xg. Their protein profile is enriched in signaling proteins, which suggests their active involvement in not only physiological but also pathological molecular processes.

This paper aim is to investigate the alteration of the molecular mechanisms in pulmonary endothelium detergent resistant membrane microdomains following a hyperlipidemic stress on two laboratory experiment models: the ApoE deficient mouse and Golden Syrian Hamster fed with a hyperlipidemic diet.

FIRST PART – CURRENT STATE OF KNOWLADGE REGARDING LIPID RFATS AND SIGNALING MOLECULAR MECHANISMS

The "fluid mosaic" was hypothesized in 1972 (Singer and Nicolson, 1972) to explain the structural and functional organization of the plasma membrane and answered questions regarding its functions: transport processes, protection, cell-cell contact, signaling mechanisms.

Subsequent studies (Pike, 2003; Engelman, 2005) have shown that the plasma membrane is more mosaic than fluid and proposed a new model for membrane organization, in which it appears "patched" with portions segregated in different thickness and composition.

However, the concept of membrane microdomains appeared much earlier (Klausner et al., 1980; Simionescu et al., 1981, van Meer and Simons, 1983, etc.) and the “lipid raft” term was proposed in 1997 (Simons and Ikonen, 1997), describing floating islands on the membrane surface. Lipid rafts sites are enriched in cholesterol, glycosphingolipids, saturated phospholipids and specialized proteins, whose rigid packaging allow phase separation. Today, they are seen as dynamic nano-ordered protein assemblies, rich in sphingolipids and cholesterol, in which the metastable state can be activated under the influence of stimuli to attract and achieve specific lipid-lipid, protein-lipid and protein-protein interactions resulting in the formation of higher-order signaling platforms (Hancock, 2006).

Lipid raft functions in different cell types have been the study of many groups of researchers over the years. These include polarization, cell signaling, endocytosis, cholesterol homeostasis, cell-cell and cell-pathogen adhesion processes (Jacobson et al., 2007), but their most valued role is the ability to concentrate molecules involved in cell signaling. It was revealed that the coalescence of membrane microdomains results in a more efficient signaling process. Also a major feature of these microdomains, especially of caveolae (membrane subdomains) is the transport function through endocytosis and transcytosis of specific molecules in particular in endothelial cells (Palade et al., 1981, Vasile et al., 1983; Nistor and Simionescu, 1986). For example,

caveolaeare the main route of the albumin transport in endothelial cells, using a transcytosis process (Predescu et al. 1988 Antohe et al. 1991). Also, using caveolae as a transport vehicle, aminopeptidase P antibody passes the endothelium from the blood flow to the lung tissue (Oh et al. 2007).

Observations that many membrane proteins involved in cell signaling, adhesion and migration processes are located in detergent resistant membrane microdomains, together with data from studies on sterols, sphingolipids and proteins nano-assemblies in living cells, increased the interest in the biological functions of tlipid rafts and their role in inflammation and immune response. It seems that the rafts enriched in cholesterol and sphingolipidsare major regulators of atheroma pathophysiology by the activation of signaling pathways involved in the generation of atherosclerotic lesions. The type and plasma membrane lipid composition *per se* is a major determinant of protein localization in lipid rafts, and subtle changes in plasma membrane lipid composition and especially cholesterol content can result in the overall alteration of signaling pathway cascades.

Atherosclerosis is a chronic, multi-factorial disease and is one of the leading causes of death especially in developed countries (Naghavi et al., 2003). Although for a long time this pathology was seen as slow and irreversible, new knowledge in the field reveals that it is a multi-regional, dynamic and when early treated reversible process. Endothelial cells are specifically involved in the development and progression (or regression) of atherosclerotic lesions. Vascular endothelium is the first layer that interacts with different cellular stress pro-atherogenic or biochemical factors in the blood plasma, resulting in the endothelial and vascular dysfunction (Blankenberg et al., 2003; Simionescu and Antohe, 2006, Pavlides et al., 2014).

The pulmonary endothelium is directly involved in vital functions of the body, such as the exchange solution, fibrinolysis, coagulation, regulation of vasculogenesis and angiogenesis, interaction with platelets and leukocytes (Lucas, 2008). Although atherosclerotic plaques are not characteristic to this region, various studies have suggested that lung endothelium can be modulated for health improvement using angiotensin converting enzyme inhibitors and statins (Lucas, 2008 Osto et al., 2007). Published data have shown that atherosclerotic risk factors such as lipid rich diet (Uyy et al., 2013; Haraba et al., 2011), hypertension (Sellers et al., 2008), reactive oxygen

species (Lang et al. 2002), a disturbed production of nitric oxide (South et al., 2007), over-production of cytokines, chemokines (Hamacher et al., 2002, Bechara et al., 2007) and impaired coagulation and fibrinolysis processes (Lucas et al., 1997, Russell et al., 2003), can activate the pulmonary endothelium, affecting multiple signaling pathways, with significant impact on the stability of atherosclerotic plaques in the vascular areas prone to atheroma formation.

Statins are blood lipid lowering drugs, which were developed and clinically tested for regulation of cholesterol biosynthesis. Several studies measuring hemostatic parameters have also demonstrated the beneficial effects of statins on endothelial cells, including promoting the pro-fibrinolytic state (Seljeflot et al., 2002).

Given the many still unresolved issues in this field, we focused on the molecular signaling mechanisms localized at the plasma membrane level using hyperlipidemicexperimental animal models (Golden Syrian Hamsters and ApoE deficient mice) and biochemical, immunological, mass spectrometry analysis and bioinformatics tools. Using the existing methods for isolatingdetergent resistant membrane microdomains, weobservedthe DRM protein profile alteration induced by hyperlipidemic diet (associated or not with ApoE protein deficiency).

SECOND PART – ORIGINAL CONTRIUTIONS

To highlight the molecular mechanisms involved in membrane microdomains signaling affected by hyperlipidemia, we used two experimental hyperlipidemic animal models: the ApoE deficient mouse and the Syrian Golden hamster, subjected to hyperlipidemic diet. Controls were represented by a group of C57 Black mice and a group of hamsters with standard diet. Also in this study we focused on statin treatment effects following a high fat intake. Thus, after 6 weeks and 6 months of high lipid diet, the ApoE deficient mice and Syrian Golden hamsters exhibited significantly higher levels of cholesterol and triglycerides compared to control groups. Statin treatment resulted in significant decreases in serum levels of cholesterol and triglycerides. Microscopy experiments revealed lipid deposits in the heart valves successive cryosections in both hyperlipidemia groups of animals.

Membrane microdomains were isolated and purified on the basis of their insolubility by non-ionic detergents, and selective flotation in a density gradient (Sargiacomo et al. 1993). Of the 12 collected fractions following an ultracentrifugation process (200,000xg), the 4th and 5th fractions presented a higher concentration of protein, cholesterol and glycerolipids. These two fractions were combined and called non-ionic detergent resistant membrane microdomains (DRM), and subsequently used in qualitative and quantitative experiments. It was also demonstrated that the isolated DRMs were of endothelial origin, through detection of angiotensin converting enzyme peak activity in the two fractions. In addition, we observed an increased activity in the ApoE deficient mice group that received a hyperlipidemicdiet and the statin treatment one, thus suggesting endothelial activation due to hyperlipidemicstress. DRM isolation validation was performed using immunological experiments and mass spectrometry data.

DRMs isolated from the hamsters groups were solubilized and purified for protein extraction. The proteinswereprelabeled with fluorescent cyanine dyes and subjected to isoelectric focusing separation (according to the isoelectric point) and single dimension electrophoresis (for separation according to molecular weight) using the 2D-DIGE

approach. Using an imaging system based on laser scanning together with high-performance bio-informatics analysis, we detected ~ 1500 different protein spots in the range of 4-9pH. Also, the 2D-DIGE technique allowed us to obtain a good reproducibility between the analyzed samples, which resulted in a high degree of confidence in subsequent quantitative analysis which revealed 48 differently expressed protein spots between the control group and those receiving statin treatment, 85 spots with altered abundance determined by the hyperlipidemia diet and statin treatment. In total, over 200 protein spots were observed with significantly altered intensity. These spots were automatically excised from gels and processed for mass spectrometry analysis using a MALDI-TOF system and the Peptide Mass Fingerprinting technique. This led to the identification of structural proteins (actin variants, vimentin, tubulin, myosin), cytokines (interferon, interleukins), various signaling molecules (GTPases, receptors, HSPs, etc.) of trafficking and cellular transport proteins (annexin ATP synthase, membrane channels, etc.), and numerous enzymes (synthases, reductases, dehydrogenases, nucleotidase, caspases, etc.). Among these molecules, we observed that the hyperlipidemic diet resulted in the over-expression (beta actin, vimentin, interferon, interleukin-1 precursor, inositol phosphatase F, caspase-12, annexin A3 and fatty acid synthase), or under-expression (tubulin, Ras, Grp94) of some molecules. Statin therapy resulted in abundance decrease for some protein spots to a level comparable to the control (HDL binding protein, annexin A3, Grp94), and an inverse effect for others(MHC class II antigen, CRA kinase, protein trafficking of nitric oxide synthase).

High performance techniques based on mass spectrometry coupled with nano-liquid chromatography were applied for qualitative and relative quantitative analysis of mice isolated DRMs. Using the MudPIT approach we identified 1279 proteins in the control group, 1233 in the hyperlipidemic one and 1239 in the group of mice that received statin therapy. Gene Ontology based analysis revealed that, in terms of *Cellular Components*, most of the identified proteins were indeed of membrane origin. However, we also identified with high confidence proteins of nuclear, cytoskeletal, cytosolic, mitochondrial and extracellular origin. The distribution of proteins based on *Biological Process* demonstrated the proteins' primary role in metabolic processes, regulation of biological processes, response to stimuli, cell organization and biogenesis,

cell communication, development and cell differentiation. Classification based on *Molecular Functions* demonstrated a main representation of proteins in molecular interaction events, but also in catalytic activity, interaction with nucleotide, metal ions binding activity and molecular structure. The relative quantification analysis revealed 654 significantly differentially expressed proteins in the hyperlipidemicand statin treatment groups relative to the control. Their spatial distribution by Principal Component Analysis revealed a very good differentiation between the three DRM protein groups. 29 of these proteins were closely related to cytoskeleton-DRM interaction sites. Their analysis revealed that hyperlipidemia stress statin therapy affectedthree over-represented KEGG signaling pathways: *Regulationof Actin Cytoskeleton, Focal Adhesion and Adherence Junction*.

Moreover, immunological, biochemical and mass spectrometry studies were employed to highlight a number of DRM resident or associated protein molecules with significantly altered abundance caused by the hyperlipidemic stress and statin therapy. Thus, it was demonstrated that the cardiopulmonary dysfunction affected the expression of caveolin-1 (significantly over-expression), and PTRF (significantly under-expression). Also we demonstrated co-fractionation and altered expression of dynamin (under-expression caused by the hyperlipidemic condition),filamine (over-expressiondue to the hyperlipidemicstress), Hsp70 (significantly increased expression in the hyperlipidemic mice group) and Hsp90 (significantly decreased expression in the hyperlipidemic group) in the isolated DRMs. These results led to the correlation of secreted HSPs serumand tissue levels, emphasizing the possible role of DRM in their transport and regulation.

High-performance nano-chromatography mass spectrometry experiments were performed for the DRM protein profiles hyperlipidemic mice and hamsters comparison. The high percentage (~ 65%) of identified hamster proteins attributed to the MusMusculusorganism together with their similar characteristic chromatographic profiles, demonstrateda high degree of sequence homology between the two organisms. Also, the Gene Ontology data analysis performed with Protein Center, revealed similar protein profiles, the majority of them being of membrane, extracellular, cytoskeletal, nuclear and mitochondrial origin, with roles in metabolic processes, response to stimuli, cellular organization and biogenesis, involved inprotein and

nucleotide binding and catalytic activity. The relative quantitative analysis revealed 830 proteins whose abundanceswere altered by hyperlipidemia and statin therapy. The 422 different proteins uniquely assigned to the mice group were found in the following overrepresented KEGG signaling pathways: Antigen Processing and Presentation, TCA and Drug Metabolism. In the hamster groups alone, 288 proteins were found with significantly altered expressions that were involved in Adhesion Junctions and Oxidative Phosphorylation. Interestingly, hyperlipidemia acted on a common pool of 120 proteins in both animal models. These were involved in Leukocyte Transendothelial Migration, Tight Junctions,Oxidative Phosphorylation and Phagosome pathways.

INTRODUCERE

Ateroscleroza reprezintă o maladie în special a arterelor de calibru mare și mediu cu manifestări clinice severe (plăci aterosclerotice) și finalitate tragică (ischemie cardiacă, cangrena membrelor inferioare, encefalopatie ischemică, infarct miocardic, infarct cerebral). Hiperlipidemia este un factor major de risc in ateroscleroză, conținutul crescut de lipide circulante fiind de obicei contracarat prin tratament cu statine.

Celulele endoteliale sunt primele care iau contact și sunt activate de factorii pro-aterogenici, ca de exemplu nivelele crescute de colesterol și trigliceride din lipoproteinele circulante, care le determină disfuncționalitatea. Endoteliul pulmonar este implicat direct într-o serie de funcții vitale organismului (schimb de soluți, reglarea tonusului vascular, vasculogeneză, angiogeneză) și deși nu dezvoltă în mod normal plăci aterosclerotice, acesta poate fi activat de factorii stresanți, pro-aterogenci (dietă hiperlipidemică, hipertensiune, producție dereglată de oxid nitric, etc.) cu implicații în alterarea căilor de semnalizare din zonele predispuse la apariția plăcilor.

Studiile de specialitate au dovedit importanța majoră a mecanismelor de semnalizare de la nivelul membranelor biologice, bariere structurale și funcționale implicate activ în homeostazia celulei. Microdomeniile membranare reprezintă nano-ansamble dinamice din componența membranelor, cu un conținut proteic și lipidic special și rol în reglarea transportului celular, homeostazia colesterolului, etc. Structura particulară a acestora determină caracteristica de a fi insolubile în detergenții non-ionici și flotația într-un gradient de densitate ca urmare a ultracentrifugării la 200000xg. Profilul proteic, îmbogățit în proteine de semnalizare, sugerează implicarea activă a lor în procese moleculare fiziologice, dar și patologice.

Prezenta lucrare a avut ca scop investigarea mecanismelor moleculare de la nivelul microdomeniilor membranare izolate din endoteliul pulmonar, ca urmare a inducerii unui stres hiperlipidemic în două modele experimantale de laborator: șoarecele ApoE deficient și Hamsterul Sirian Auriu supus unei diete hiperlipidemice.

PARTEA I – STADIUL ACTUAL AL CUNOȘTINȚELOR PRIVIND *RAFT*-URILE LIPIDICE Și MECANISME MOLECULARE IMPLICATE ÎN SEMNALIZARE

Modelul „mozaicului fluid” a fost enunțat în 1972 (Singer și Nicolson, 1972) pentru explicarea organizării structurale și functionale a membranei plasmatice. Acesta raspundea la întrebările referitoare la rolurile pe care membrana plasmatică le îndeplinește: procese de transport, protecție, contacte celula-celula, mecanisme de semnalizare.

Studiile ulterioare (Pike, 2003; Engelman, 2005) au dovedit că membrana plasmatica este mai mult mozaic decât fluid, propunându-se un nou model de organizare membranara, în care aceasta apare „peticită”, cu porțiuni segregate, distincte în grosime și compoziție.

Totuși, conceputul de microdomenii membranare a apărut mult mai devreme (Klausner et al., 1980; Simionescu et al., 1981; van Meer și Simons, 1983, etc.) iar denumirea de *raft*-uri lipidice a fost propusă in 1997 (Simons și Ikonen, 1997), acestea fiind descrise ca insule plutitoare de pe suprafața membranei. *Raft*-urile lipidice sunt îmbogățite în colesterol, glicosfingolipide, fosfolipide saturate, a căror împachetare rigidă permite o separare de fază, dar și proteine specializate. În prezent, acestea sunt văzute ca nano-ansamble proteice ordonate, dinamice, bogate în sfingolipide și colesterol, în care starea de repaus metastabilă poate fi activată sub acțiunea unor stimuli să atragă și să realizeze interacțiuni specifice lipid-lipid, proteină-lipid și proteină-proteină cu formarea unor platforme de semnalizare (Hancock, 2006).

Funcțiile *raft*-urilor lipidice în diferite tipuri celulare a reprezentat domeniul de studiu pentru multe grupuri de cercetători de-a lungul anilor. Printre acestea se numără polarizarea, semnalizare celulara, endocitoza, homeostazia colesterolului, procese de adeziune celulă-celulă și celulă-factor patogen (Jacobson et al., 2007), însă cel mai apreciat rol al acestora este posibilitatea de recrutare și concentrare a moleculelor implicate în semnalizarea celulară. S-a evidențiat că prin coalescența microdomeniilor membranare se eficientizează procesul de semnalizare. De asemenea o caracteristică majoră a microdomeniilor membranare, în special a caveolelor (subdomeniu

membranar) este funcția de transport realizată prin endocitoză și transcitoză unor molecule specifice în particular în celulele endoteliale (Palade et al., 1981; Vasile et al., 1983; Nistor și Simionescu, 1986). De exemplu, caveolele reprezintă principala rută de transport a albuminei în celulele endoteliale, printr-un proces de transcitoză (Predescu et al., 1988, Antohe et al., 1991). De asemenea, prin caveole se realizează transportul anticorpilor împotriva aminopeptidazei P din fluxul sangvin prin endoteliu către țesutul pulmonar (Oh et al., 2007).

Observațiile că numeroase proteine membranare implicate în semnalizare celulară, procese de adeziune și migrare, sunt localizate în microdomeniile membranare, împreună cu datele furnizate de studiile pe nano-ansamble de steroli, sfingolipide și proteine în celule vii, a crescut interesul privind funcțiile biologice ale *raft*-urilor lipidice și în special rolul acestora în inflamație și răspunsul imun. Se pare că microdomeniile îmbogățite în colesterol și sfingolipide sunt reglatori majori ai patofiziologiei ateromului prin declanșarea căilor de semnalizare implicate în generarea leziunilor aterosclerotice. Tipul și compoziția lipidică a membranei plasmatice *per se* reprezintă un determinant major în localizarea proteinelor în *raft*-uri lipidice, iar schimbări subtile în compoziția lipidică a membranei plasmatice și în special în conținutul de colesterol pot rezulta în modificări generale ale cascadelor de semnalizare.

Ateroscleroza a fost percepută multă vreme ca un proces lent și ireversibil. Noile cunoștințe în domeniu relevă însă faptul ca aceasta este un proces multi-zonal, dinamic și totodată reversibil atunci când tratamentul este aplicat din timp. Celulele endoteliale sunt în mod special implicate în dezvoltarea și progresia (sau regresia) leziunilor aterosclerotice. Endoteliul vascular este primul strat celular care interacționează cu diferiți factori de stres pro-aterogeni sau modificări biochimice de la nivelul plasmei sangvine, în urma cărora se activează, stare care se traduce prin disfuncție endotelială și vasculară (Blankenberg et al., 2003; Simionescu și Antohe, 2006; Pavlides et al., 2014).

Endoteliul pulmonar este implicat activ in realizarea funcțiilor vitale ale organismului, precum schimbul de soluți, fibrinoliză, coagulare, reglarea vasculogenezei și angiogenezei, interacția cu plachetele și leucocitele (Lucas, 2008). Deși plăcile

aterosclerotice nu se dezvoltă în mod normal în vasculatura pulmonară, diferite studii sugerează ca endoteliul pulmonar în mod particular reprezintă un situs biologic determinant, care poate fi modulat pentru îmbunătățirea sănătății folosind inhibitori pentru enzima de conversie a angiotensinei și statine (Lucas, 2008, Osto et al., 2007). Date publicate au demonstrat că factori de stres aterosclerotici precum dieta bogată în lipide (Uyy et al., 2013; Haraba et al., 2011), hipertensiunea (Sellers et al., 2008), speciile reactive de oxigen (Lang et al., 2002), o producție dereglată de oxid nitric (Sud et al., 2007), supra-producția de citokine, chemokine (Hamacher et al., 2002; Bechara et al., 2007) și dereglarea proceselor de coagulare și fibrinoliză (Lucas et al., 1997; Russel et al., 2003), pot activa endoteliul pulmonar, afectând multiple căi de semnalizare, cu impact semnificativ asupra stabilității plăcilor aterosclerotice din zonele vasculare predispuse la apariția acestora.

Statinele sunt medicamente care scad nivelul lipidelor din sânge, fiind dezvoltate și testate clinic pentru caracteristicile speciale de a regla biosinteza colesterolului. Diferite studii de măsurare a parametrilor hemostatici au demonstrat de asemenea efectele benefice ale statinelor asupra celulelor endoteliale, inclusiv promovarea unei stări pro-fibrinolitice (Seljeflot et al., 2002).

Având in vedere numeroasele aspecte nerezolvate încă, ne-am propus ca obiectiv general sa ne concentrăm asupra mecanismelor moleculare de semnalizare localizate la nivelul membranei plasmatice utilizând modele animale experimentale de hiperlipidemie (Hamsteri Sirieni Aurii și șoareci ApoE deficienți) și analize biochimce, de spectrometrie de masa și bioinformatice. Utilizând metodele deja existente pentru separarea microdomeniilor membranare, am urmărit modificările induse de dieta hiperlipidemică asociată sau nu cu modificări genice (deficiențăîn gena ApoE) în compoziția proteică a microdomeniilor membranare insolubile în detergenți non-ionici (DRM) și am analizat modificarea proteomului și a căilor de semnalizare alterate.

PARTEA A II-A – CONTRIBUȚII ORIGINALE

Pentru evidențierea mecanismelor moleculare implicate în semnalizare localizate la nivelul microdomeniilor membranare în hiperlipidemie, am utilizat două modele experimentale de animale de laborator hiperlipidemice: șoarecele ApoE deficient și Hamsterul Sirian Auriu, supuși unor diete hiperlipidemice. Controalele au fost reprezentate de un lot de șoareci C57 Black, respectiv un lot de hamsteri cu dietă standard. De asemenea, în acest studiu au mai fost folosite loturi de animale care după dieta hiperlipidemică au fost trecuți pe dietă standard, în paralel cu un tratament cu statină. Astfel, după dieta hiperlipidemică, șoarecii ApoE deficienți și Hamsterii Sirieni Aurii au prezentat nivele semnificativ crescute de colesterol și trigliceride serice față de loturile control. Tratamentul cu statină a determinat scăderea semnificativă a nivelelor de colesterol și trigliceride serice. Experimente de microscopie optică au evidențiat depozite lipidice la nivelul valvelor cardiace prelevate în serie prin crioprotecție și secționate la criotom în ambele loturi hiperlipidemice ale celor două tipuri de animale.

Microdomeniile membranare au fost izolate și purificate pe baza caracteristicii acestora de a fi rezistente la solubilizarea cu detergenți non-ionici și a flotației selective într-un gradient de densitate (Sargiacomo et al., 1993). Din cele 12 fracții colectate în urma ultracentrifugării la 200000xg s-a evidențiat o concentrație crescută de proteine, colesterol și glicerolipide in fractiile 4 și 5, de la interfața dintre soluțiile de 5%, respectiv 30% sucroză. Aceste 2 fracții au fost combinate și numite microdomenii membranare rezistente la solubilizarea cu detergenți non-ionici (DRM), fiind ulterior utilizate în experimentele calitative și cantitative. S-a demonstrat de asemenea, originea preponderent endotelială a microdomeniilor izolate, prin detectarea maximului de activitate al enzimei de conversie a angiotensinei, la nivelul celor două fracții amintite. În plus, s-a observat o activitate crescută la nivelul șoarecilor ApoE deficienți care au primit o dietă hiperlipidemică și a celor care au primit tratament cu statină, sugerându-se astfel activarea endoteliului ca urmare a stresului hiperlipidemic. Validarea izolarii

microdomeniilor membranare s-a realizat prin experimente imunologice și de spectrometrie de masă.

DRM-urile extrase de la loturile de hamsteri au fost solubilizate și purificate pentru extracție proteică. Acestea au fot premarcate cu cianine fluorescente și supuse focalizării izoelectrice pentru separarea în funcție de punctul izoelectric și electroforezei unidimensionale pentru separare în funcție de greutatea moleculara (2D-DIGE). Folosirea unui sistem de imagistică pe baza de scanare, foarte performant împreună cu analiza bio-informatica ulterioara, au permis detecția a ~1500 de spoturi proteice diferite în domeniul de pH 4-9. Tehnica 2D-DIGE utilizată a permis de asemenea obținerea unei foarte bune reproductibilități între probele analizate, ceea ce a determinat un grad înalt de confidență în analiza cantitativă ulterioară. În urma acesteia, s-au evidențiat 48 de spoturi proteice diferit exprimate între grupul control și cel care a primit tratament cu statină, 85 de spoturi cu abundență alterată determinată de dieta hiperlipidemică și tratamentul cu statina, în total observându-se peste 200 de spoturi proteice cu expresii alterate. Spoturile astfel analizate au fost excizate în mod automat din geluri și procesate pentru analiza spectrometrica de masă utilizând un sistem de tip MALDI-TOF prin *Peptide Mass Fingerprinting*. Aceasta a relevat identificarea unor proteine de natură structurală (variante de actină, vimentină, tubulină, miozină), citochine (interferon, interleuchine), a diferite molecule cu rol general în semnalizare (GTP-aze, receptori, Hsp-uri, etc), a unora cu rol în trafic și transport celular (anexină, ATP-sintază, canale membranare, etc), precum și numeroase enzime (sintaze, reductaze, dehidrogenaze, nucleotidaza, caspaze, etc). Dintre aceste molecule, s-a observat că dieta hiperlipidemică a acționat prin creșterea expresiei unor molecule (beta actinei, vimentinei, interferonului, precursorului interleukinei-1, inozitol fosfatazei F, caspazei-12, anexinei A3 și sintazei de acid gras), pe când în cazul altora aceasta a fost diminuată (tubulină, Ras, Grp94). Tratamentul cu statină a determinat scăderea abundenței până la un nivel comparabil cu controlul (*HDL binding protein*, anexina A3, Grp94), dar și un efect invers în cazul antigenului MHC de clasa II, kinazei CRA, proteinei de trafic a sintazei oxidului nitric .

Tehnica de înaltă performanța bazată pe spectrometrie de masă cuplată cu nano-cromatografia de lichide a fost aplicată pentru analiza calitativă și cantitativă

relativă a DRM-urilor extrase de la loturile de șoareci. Astfel, prin tehnica *MudPIT*, au fost identificate 1279 de proteine în grupa control, 1233 în cea hiperlipidemică și 1239 la nivelul grupei de șoareci care a primit tratament cu statină. Analiza în bazele de date de *Ontologie Genică* au relevat că, din punct de vedere al *Componentei Celulare*, majoritatea proteinelor identificate sunt într-adevăr de origine membranara. Totuși, s-au identificat cu mare confidență și proteine de origine nucleară, citoscheletală, citosolică, mitocondrială și extracelulară. Distribuția proteinelor pe baza *Procesului Biologic* a demonstrat un rol principal al acestora în procese metabolice, reglarea proceselor biologice, răspuns la stimuli, organizare celulară și biogeneză, comunicare celulară, dezvoltare și diferențiere celulară. Categoria de *Funcții Moleculare* ale proteinelor este bazată pe același tip de evaluare și a demonstrat o principală reprezentare a proteinelor în evenimente de interacție moleculară, dar și în activitate catalitică, interacție cu nucleotide, legarea ionilor metalici și activitate structurală moleculară. În urma analizei de cuantificare relativă, s-au obtinut 654 de proteine diferit exprimate în grupele hiperlipidemice și cu tratament cu statină relativ la grupa control. Distribuția spațială cantitativă a acestora, prin *Analiza Componenților Principali*, a relevat o diferențiere foarte buna a grupelor de DRM-uri luate în lucru. Dintre proteinele diferit exprimate în mod semnificativ, 29 de proteine au fost strâns corelate cu interacția citoschelet-DRM-uri. Analiza acestora a relevat că stresul hiperlipidemic și tratamentul cu statină afectează în mod particular următoarele căi de semnalizare *KEGG*, care au fost găsite suprareprezentate din punct de vedere statistic: *Reglarea Citoscheletului Actinic*, *Adeziune Focala* și *Joncțiuni Aderente*.

De asemenea, prin studii imunologice, biochimice și de spectrometrie de masa au fost evidențiate molecule proteice rezidente ori asociate DRM-urilor extrase din loturile de șoareci, a căror expresie a fost alterată semnificativ de stresul hiperlipidemic și tratamentul cu statină. Astfel, s-a demonstrat că disfuncția cardiopulmonară apărută ca urmare a hiperlipidemiei, afectează expresia caveolinei-1, aceasta crescând în mod semnificativ, dar și a PTRF, care scade semnificativ. De asemenea, s-a demonstrat co-fracționarea și alterarea expresiei dinaminei (care scade semnificativ în grupa hiperlipidemică), filaminei (care crește in grupa hiperlipidemică), a Hsp70 (expresie semnificativ crescutăîn grupa hiperlipidemică) și Hsp90 (expresie semnificativ scazută

în grupa hiperlipidemică) cu DRM-urile izolate. Rezultatele obținute au dus la corelarea nivelului secretat în ser al Hsp-urilor menționate cu nivelul tisular al acestora, evidențiindu-se un posibil rol transportor și reglator al DRM-urilor.

Prin experimente de spectrometrie de masă de înaltă performanță, s-a realizat compararea profilelor proteice ale DRM-urilor izolate de la lotul de șoareci și de la lotul de hamsteri. Prin procentul mare de proteine identificate atribuite organismului Mus Musculus în grupele de hamsteri (~65%), precum și prin evaluarea profilelor cromatografice, s-a demonstrat înalta omologie a celor doua organsime. De asemenea, analiza de Ontologie Genică realizată cu Protein Center, a evidențiat profilul asemănător al proteinelor identificate de la cele doua loturi, majoritatea fiind de origine membranară, extracelulară, citoscheletală, nucleară și mitocondrială, cu rol în procese metabolice, răspuns la stimuli, organizare celulară și biogeneză, fiind implicate în interacție proteică, activitate catalitică și legarea nucleotidelor. Analiza cantitativă relativă a relevat 830 de proteine a căror abundență este modificată de hiperlipidemie și tratamentul cu statina. Cele 422 de proteine diferit exprimate și unic atribuite lotului de șoareci au fost găsite în căile KEGG de semnalizare suprareprezentate statistic: *Procesarea și Prezentarea Antigenului*, *Calea TCA* și *Metabolismul Medicamentelor*. În lotul de hamsteri, au fost găsite 288 de proteine cu expresie semnificativ alterată de stresul hiperlipidemic și tratamentul cu statină. Acestea au fost implicate în *Joncțiuni Aderente* și *Fosforilarea Oxidativă*. În mod interesant, hiperlipidemia a acționat asupra a 120 de proteine atât în lotul de șoareci cât și în cel de hamsteri. Acestea au fost implicate în *Migrarea transendotelială leucocitară*, *Joncțiuni Strânse*, *Fosforilarea Oxidativă* și *Calea Fagozomală*.

Astfel, se poate concluziona că moleculele și căile de semnalizare identificate cu mare confidență și semnificație statistică pot reprezenta noi direcții de studiu a implicațiilor extraordinare pe care hiperlipidemia le demonstrează în funcționalitatea țesuturilor si organelor.

Introducere și obiectivele generale ale tezei

Elaborarea prezentei teze a pornit de la marea problematică a medicinei moderne, și anume ateroscleroza, și mai exact de la totalitatea și severitatea determinărilor aterosclerotice la nivel vascular periferic (carotidian și la nivelul membrelor inferioare). Severitatea bolii aterosclerotice la nivel periferic, și nu numai, este influențată de prezența factorilor de risc (diabetul zaharat, dislipidemia, fumatul, vârsta, asocierea altor determinări aterosclerotice, obezitatea) și de complexitatea acestora. Evoluția bolii aterosclerotice este galopantă în absența corecției acestor factori de risc sau a neglijării medicației sau a stilului de viață nesănătos. Această teză de doctorat și-a propus să găsească corelații între parametrii plasmatici lipidici și inflamatori și boala aterosclerotică, precum și identificarea unor markeri ai evoluției bolii aterosclerotice. Persistența factorilor de risc în zonele arteriale pro-aterogene determină apariția și progresia unei cascade de evenimente ce se traduce prin apariția și progresia plăcii de aterom. Etapele formării plăcii de aterom încep cu acumularea subendotelială a lipoproteinelor modificate oxidativ, care declanșează activarea celulelor endoteliale (CE), urmată de disfuncția endotelială, cu apariția unor molecule de adeziune celulară responsabile de declanșarea unui puternic răspuns inflamator. Celulele inflamatorii pătrunse sub endoteliu, prin factorii pe care îi secretă, determină acumularea de celule musculare netede la nivelul intimei arteriale, cu formarea capului fibros. Celulele musculare netede suferă și ele un process de transformare, într-un fenotip secretor, dând naștere unei lamine bazale hiperplazice, multistratificate, cu o matrice extracelulară bogată în fibre de colagen și fibrile (Simionescu and Sima, 2012). În final, se formează placa de aterom, care poate fi stabilă sau instabilă, în funcție de compoziția celulară a acesteia. Eroziunea sau subțierea capului fibros expune matricea extracelulară subendotelială bogată în celule proinflamatorii și procoagulante, celulelor din circulația sanguină, inițiindu-se astfel procesul de tromboză. Această cascadă de evenimente este amplificată și accelerată în cazul diabetului zaharat, începând cu apariția timpurie a disfuncției endoteliale (Toma et al 2021), a plăcii aterosclerotice și trombozarea acesteia.

Structura tezei de doctorat

În **prima parte** a tezei de doctorat am abordat problematica pacientului „vascular”, adică a pacientului care asociază una sau mai multe determinări aterosclerotice, de obicei cu multipli factori de risc asociați și neglijați, în proporție ridicată. Pacientul ajunge la chirurgul vascular deoarece nu mai suportă durerea de repaus sau nocturnă, sau când leziunea trofică de la nivelul piciorului capătă un miros fetid pe care pacientul sau familia nu îl mai poate suporta, sau când leziunile vasculare de la nivelul arterelor carotide se soldează cu un accident vascular și atunci este nevoie de un examen de specialitate. De asemenea, am descris pe scurt modalitatea de formare a plăcii de aterom și mecanismele și moleculele implicate în acest proces aterosclerotic.

Partea a doua a lucrării, cea de contribuții originale cuprinde:

- criteriile de înrolare a pacienților și descrierea tipurilor de intervenții chirurgicale aplicate pacienților înrolați în studiu;
- metodele biochimice și imunochimice pentru caracterizarea proteinelor și lipoproteinelor plasmatice și metodele de biologie moleculară pentru analiza factorilor epigenetici (microARN) în probe de plasmă și aterom;
- identificarea unor parametrii biochimici si epigenetici cu potențial de markeri ai gravității bolii stenotice carotidiene și ai bolii arteriale periferice în două studii specifice.

Am stabilit grupele de pacienți cu stenoză carotidiană și boală arterială periferică, grupul control pentru fiecare din cele două categorii de pacienți, datele antropometrice, diagnosticele secundare, tratamentul medicamentos al acestor categorii de pacienți. Am studiat două teritorii vasculare (arterele carotide și arterele periferice ale membrelor inferioare) a căror afectare aterosclerotică este frecventă și produce morbiditate și mortalitate în cel mai înalt grad.

În **primul studiu**, ne-am propus să evaluăm rolul miR-223, ca potențial biomarker pentru agravarea SAC la pacienții cu vârsta peste 65 de ani și am corelat nivelele acestuia cu parametrii asociați lipoproteinelor de densitate înaltă (HDL). Concluzia acestui studiu este că pacienții cu SAC cu vârsta peste 65 de ani au prezentat o creștere semnificativă a nivelurilor miR-223-3p atât în plasmă, cât și în placa de aterom carotidiană, comparativ cu pacienții cu SAC sub 65 de ani.

În cel de **al doilea studiu**, ne-am propus să identificăm modificări ale compoziției subfracțiilor HDL_2 și HDL_3 care se asociază cu severitatea bolii arteriale periferice (BAP)

și determină alterarea funcției HDL măsurată ca efecte antiinflamatorii exercitate asupra CE umane activate cu factorul de necroză tumorală alfa (TNFα). Am urmărit să determinăm care dintre modificările identificate la nivelul constituenților HDL sunt detectabile la proteine din plasmă și ar putea prezice severitatea bolii la pacienții cu BAP, pentru a fi transpuse în laboratoarele clinice. Astfel am constatat creșterea nivelurilor de clusterina (CLU) și a activității specifice ale mieloperoxidazei (MPO) și diminuarea activității specifice a paraoxonazei (PON1) în plasmă, acestea reflectând alterarea proteinelor HDL și a funcționalității acestora. Rezultatele ar putea fi translatate în laboratoare clinice și ar putea servi la prognosticul severității BAP. De asemenea, în același studiu am analizat expresia din placa aterosclerotică și de la nivel plasmatic al hsa-miR-142-3p, hsa-miR-223-3p, hsa-miR-155-5p, hsa-miR-92a-3p și am realizat corelații cu evoluția postoperatorie pe parcursul unui an a pacienților cu BAP. Am dovedit pentru prima dată legătura dintre nivelurile miARNs din placa aterosclerotică și expresia pri-miARNs corespunzătoare în placa aterosclerotică.

I. Stadiul actual al cunoștințelor

În acest capitol am cuprins date cunoscute despre structura peretelui arterial în condiții fiziologice (tipurile de artere și structura peretelui vascular normal), ce se întâmplă în condiții patologice, cum apare ateroscleroza, fazele de apariție și dezvoltare a plăcii de aterom, precum și despre factorii de risc bine cunoscuți care determină procesul aterosclerotic. De asemenea, am prezentat date despre rolul factorilor epigenetici (microARN) în ateroscleroză.

Boala cardiovasculară (BCV), principala cauză de mortalitate în lume, este un proces complex, principalele manifestări clinice incluzând infarctul miocardic, accidentul vascular cerebral și BAP, care pot fi unice ca localizare sau cu determinări simultane la două sau trei niveluri arteriale. Procesul aterosclerotic este cel care generează BCV. Placa aterosclerotică este rezultatul acțiunii unor factori de risc, considerați ca fiind clasici (dislipidemia, stresul oxidativ, citokinele proinflamatorii, factori vasoconstrictori incriminati în hipertensiune, produși de glicooxidare asociaţi cu hiperglicemia și fumatul) sau în absența unei hipercolesterolemii sistemice, inițierea formării plăcii de aterom este o reacție inflamatorie.

Evaluarea riscului cardiovascular individual implică măsurarea factorilor de risc corelați cu riscul cardiovascular (lipidele, glicemia, vârsta, sexul, fumatul și tensiunea arterială). La acești factori clasici se încearcă stabilirea unor corelații între markerii plasmatici și boala aterosclerotică, precum și predictibilitatea evoluției bolii aterosclerotice. Este cunoscut faptul că boala vasculară afectează arterele la diferite niveluri și se caracterizează prin efecte dăunătoare la nivelul endoteliului vascular, generând disfuncție endotelială. Disfuncția endotelială este răspunsul la acțiunea factorilor de risc cardiovascular. Ea reprezintă etapa timpurie cheie în dezvoltarea aterosclerozei, dar apoi este implicată în toate etapele progresiei plăcii aterosclerotice și în apariția complicațiilor acesteia. Indiferent de factorii care o generează, formarea plăcii de aterom este un proces în care implicarea graduală a diferitelor tipuri de celule și a produșilor lor secretorii duce la o serie de secvențe de la formarea stratului lipidic la placa fibrolipidică, la ruptură si aterotromboză.

Ateroscleroza este un proces multifactorial indus și favorizat de factori de risc precum dislipidemia, stresul oxidativ și inflamator, diabetul zaharat (DZ), hipertensiunea, fumatul, îmbătrânirea și mutațiile genetice (Authors/Task Force et al., 2019) și poate fi localizat la mai multe niveluri, concomitent (coronarian, carotidian și la nivelul membrelor inferioare).

Dislipidemia se definește prin concentrații sanguine crescute de colesterol total (total cholesterol, TC) și de LDL-colesterol (LDL-C) și/sau trigliceride (TG) și scăderea colesterolului în HDL (Musunuru, 2010).

HDL sunt complexe macromoleculare alcătuite din lipide și proteine, produse în ficat și intestinul subţire, care transportă colesterol liber și esterificat, fosfolipide (phospholipids, PL), TG și apoproteine (apolipoproteine - apoAI, apoAII, apoCIII, apoE, enzime – paraoxonaza 1 (PON1), mieloperoxidaza (MPO)) în circulaţie (Camont et al., 2011, Larach et al., 2012). În plasma umană, HDL sunt reprezentate de două subfracţii majore: HDL_2 si HDL_3, cu dimensiune, densitate și compoziţie diferită (Eren et al., 2012). HDL au proprietăți anti-aterosclerotice datorită capacității lor de a prelua colesterolul în exces din țesuturile periferice transportându-l la ficat, așa-numitul revers cholesterol transport (RCT), dar și datorită potențialului lor anti-oxidant, anti-inflamator și anti-trombotic (Arora et al., 2016). Un efect atero-protector al HDL este conservarea funcției CE (). În ultimii ani, calitatea și funcția HDL au devenit un indicator consecvent al riscului de BCV (Carnuta et al., 2017, Parhofer, 2015). În cazul creșterii stresului oxidativ, HDL devine disfuncțional și prezintă un număr crescut de molecule de MPO care înlocuiesc

moleculele de PON1 (Variji et al., 2019). Astfel, HDL disfuncțional nu mai poate proteja LDL de oxidare, aceste modificări fiind factorii cheie de risc pentru inițierea și progresia plăcilor aterosclerotice. Activitatea PON1 în ser și în HDL la pacienții cu BAP este scăzută comparativ cu subiecții sănătoși, concluzia fiind că HDL se oxidează și devine disfuncțional (Tan et al., 2014, Shen et al., 2015, Luscher et al., 2014). Încercările pentru dezvoltarea de noi terapii pentru tratamentul pacienților cu BAC bazate pe stimularea ficatului și intestinului subțire de a produce HDL funcțional sunt de mare actualitate.

MicroARN-urile (miARN) sunt secvențe scurte, necodante de ARN, de 20-25 nucleotide, implicate în controlul expresiei genice. Aceste miARN orchestrează expresia genelor la nivel post-transcriptional, reglând sinteza proteinelor la nivelul ARN-ului mesager (ARNm) prin degradarea acestuia. Astfel, fiecare miARN poate deveni un factor de transcriere și un reglator al expresiei genice cu implicații în proliferarea și diferențierea celulară, apoptoză și procese inflamatorii (Vogiatzi et al., 2018). Aceste miARN sunt descrise ca reglatori în variate procese celulare întâlnite în fiziopatologia BCV (Vogiatzi et al., 2018), a cancerului (Rupaimoole and Slack, 2017), bolilor autoimune (Yan et al., 2019) și a altor afecțiuni. Mai mult, miARN se găsesc în diferite țesuturi și celule sanguine, nivelul lor plasmatic fiind propus ca un potențial biomarker în diagnosticul evenimentelor cardiovasculare, cum ar fi infarctul miocardic (Devaux et al., 2012). Există câteva date despre nivelul miARN în placa aterosclerotică (Parahuleva et al., 2018), dar nu au fost raportate studii cu privire la corelația nivelului expresiei miARN din placă și cel de la nivel plasmatic, precum și corespondentul expresiei pri-miARN în placă.

Evenimentul vascular major în stenoza arterei carotide (SAC) este reprezentat de accidentul vascular ischemic, iar dezvoltarea leziunilor la nivelul arterelor membrelor inferioare generează BAP, cu repercusiuni importante asupra calității vieții pacientului și reintegrarea lui în societate.

Ateroscleroza arterelor carotide extracraniene reprezintă o problemă majoră de sănătate, cu o mortalitate prin accident vascular ischemic situată între 10-30%. Semnele și simptomele în boala ocluzivă cerebrovasculară extracraniană sunt reprezentate de amauroza fugace, accidentul ischemic tranzitor, accidentul ischemic în evoluție și infarctul cerebral. Explorările imagistice care stabilesc diagnosticul și conduita terapeutică sunt ecografia Doppler, angio tomografia sau angio RMN, angiografia carotidiană.

Tratamentul bolii ocluzive cerebrovasculare extracraniene presupune mai multe abordări şi anume: schimbarea stilului de viaţă, tratamentul medicamentos şi, după caz, tratamentul chirurgical. Endarterectomia carotidiană (EAC) se adresează pacienților cu

SAC simptomatică, dar și unui grup de pacienți asimptomatici cu risc crescut de eveniment vascular cerebral (conform ghidurilor internaționale).

Ateroscleroza arterelor periferice a membrelor inferioare reprezintă un procent mic al mortalității globale de cauze cardiovasculare, cca 1-2%, dar reprezintă o cauză comună de morbiditate generată de reducerea mobilității, prin claudicație intermitentă, durere de repaus sau ischemie acută. BAP a membrelor inferioare poate fi simptomatică sau asimptomatică, localizată la diverse niveluri ale axului arterial periferic (artere femurale comune, profunde, superficiale, poplitee și trunchiuri gambiere) și poate determina manifestări clinice diverse, de la durere de tip claudicație intermitentă, cu reducerea progresivă a perimetrului de mers pană la durere de repaus (care nu lasă pacientul să se odihnească și care necesită de obicei folosirea unei cantități importante de opiacee) și apariția leziunilor trofice minime sau extensive de tipul gangrenei. Implicații importante în evoluția pacienților cu BAP o are și asocierea diabetului (Abou-Zamzam et al., 2007)

Diagnosticul BAP se face prin efectuarea unei anamneze minuțioase, examinarea clinică a pacientului cu aprecierea pulsurilor periferice, măsurarea indicelui gleznă-braț, efectuarea unei ecografii Doppler și a angiografiei de membre inferioare sau a unui angio CT/RMN.

Tratamentul BAP implică controlul factorilor de risc (tratamentul conservator) și tratamentul chirurgical, acesta din urmă putând fi de revascularizare (by-pass, angioplastie) sau de amputaţie.

II. Contribuții originale

Acest capitol cuprinde:

II.1. Identificarea unor parametrii biochimici și epigenetici cu potențial de markeri ai gravității stenozei arterei carotide (SAC).

II.2. Identificarea unor parametrii biochimici și epigenetici cu potențial de markeri ai gravității bolii arteriale periferice (BAP).

Identificarea unor parametrii biochimici și epigenetici cu potențial de markeri ai gravității stenozei arterei carotide (SAC) a avut ca scop evaluarea asocierii hsa-miR-223-3p (miR-223) cu vârsta la pacienții cu SAC după intervenția chirurgicală de EAC, adică estimarea rolului miR-223 ca potențial biomarker pentru agravarea SAC la pacienții cu vârsta peste 65 de ani și asocierea acestuia cu parametrii asociați HDL.

Studiul a cuprins 32 de pacienți cu SAC > 70% internați în spital pentru procedura de EAC și 28 de subiecți sănătoși control (N). Cei 32 de pacienți cu SAC, internați în spital pentru procedura de EAC, au fost împărțiți în 2 grupe, în funcție de vârstă: pacienți cu SAC cu vârsta sub 65 de ani (n = 13) și pacienți cu SAC cu vârsta peste 65 de ani (n = 19). Am selecționat pacienții în funcție de criteriile de includere și excludere pe care le-am stabilit înainte de începerea studiilor, iar intervențiile chirurgicale au respectat recomandările societăților de profil.

Au fost determinați parametrii plasmatici și au fost caracterizate proteinele plasmatice la pacienții cu (SAC (Figura 1) prin metode specifice și de asemenea s-a efectuat analiza Western blot a probelor de la pacienții cu SAC.

Am procesat specimenele de plăci aterosclerotice carotidiene pentru microscopie optică și am aplicat metode de biologie moleculară pentru analiza factorilor epigenetici (microARN) în probele de plasmă și placa aterosclerotică de la pacienții cu SAC, apoi am analizat statistic rezultatele miARN de la pacienții cu stenoza arterei carotide (SAC).

Din totalul pacienților cu SAC care au suferit intervenție chirurgicală pentru îndepărtarea plăcii carotidiene, un procent de 66,7% au prezentat o evoluție bună și 33,3% au avut o evoluție nefavorabilă. Pacienții cu SAC cu evoluție nefavorabilă a bolii au prezentat o creștere a concentrației plasmatice a TG, CRP, formei oxidate a ApoAI (MDA-ApoAI) și acidului sialic, față de cei cu evoluție favorabilă (Figura 1).

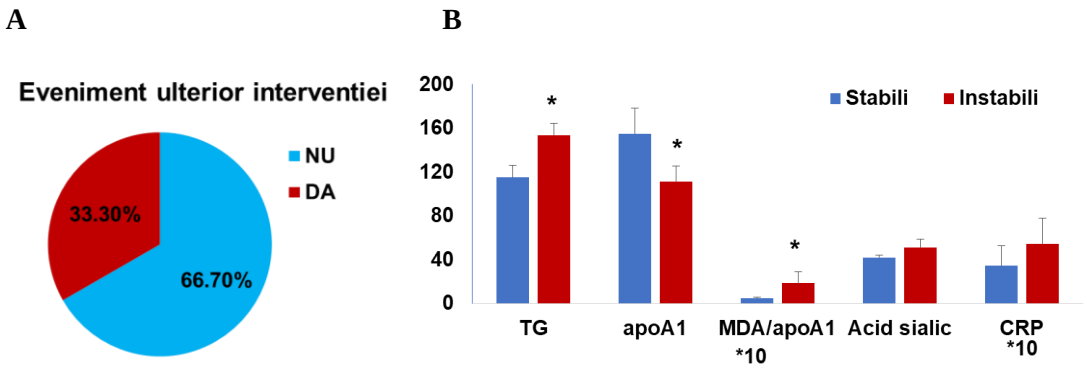

Figura 1. Corelații între evoluția pacienților cu stenoza arterelor carotide la 1 an de la intervenție (A) și parametrii plasmatici determinați inițial (B). Datele sunt exprimate ca medii ± eroare standard a mediei (SEM). *p < 0,05 SAC stabili vs. instabili.

Noutatea studiului nostru este că pacienții cu SAC cu vârsta peste 65 de ani comparativ cu pacienții cu SAC sub 65 de ani au prezentat o creștere semnificativă a nivelurilor miR-223-3p atât în plasmă, cât și în placa de aterom carotidiană (Figura 2).

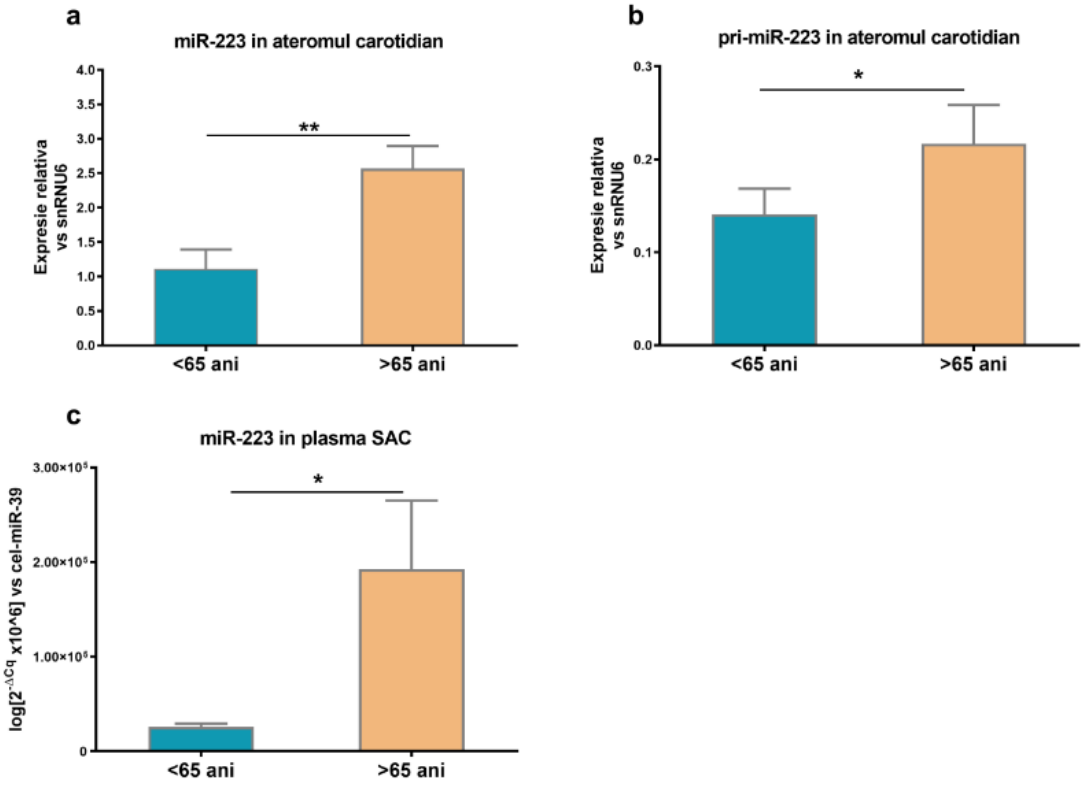

Figura 2. **Nivelurile miR-223-3p la pacienții cu SAC.** Niveluri de miR-223-3p (a) și pri-miR-223 (b) în ateromul carotidian și de miR-223-3p în plasmă (c) la pacienții cu SAC cu vârsta peste 65 de ani comparativ cu cei sub 65 de ani. Datele sunt ilustrate sub formă de histograme cu bare de eroare SEM. * $p < 0,05$, ** $p < 0,01$ comparativ cu grupul < 65 ani.

Din câte știm, acesta este primul studiu care raportează corelația nivelurilor miR-223-3p în plasmă și placa de aterom carotidiană cu vârsta pacienților cu SAC.

Am demonstrat în acest capitol o producție sporită de miR-223-3p, local și specific în celulele ateromului carotidian de la pacienții vârstnici cu SAC, asociată cu expresia crescută local a pri-miR-223, aceste date corelându-se cu observațiile grupului lui Li (Li et al., 2017) care susțin ipoteza că la pacienții vârstnici cu SAC, o producție sporită de miR-223 apare în plăcile aterosclerotice ca răspuns la diferiți factori oxidativi și inflamatori ce ar putea afecta activitatea promotorului miR-223.

Împreună, datele noastre și ale celorlalte grupuri sugerează că:

1. nivelurile crescute de miR-223-3p plasmatice observate la pacienții vârstnici cu SAC se corelează cu producția locală crescută de miRNA în ateromul carotidian,
2. nivelurile crescute de miR-223-3p se corelează cu procesele oxidative și inflamatorii care apar în timpul îmbătrânirii,
3. modularea expresiei miR-223-3p ar putea fi utilizată ca o posibilă abordare terapeutică pentru prevenirea restenozei după endarterectomie la pacienții cu SAC.

O limitare a prezentului studiu este numărul relativ mic de pacienți cu SAC analizați. În ciuda acestui fapt, analizele statistice utilizate, împreună cu distribuția miR-223 în plasmă și aterom carotidian, au dat rezultate statistic semnificative. O altă limitare al studiului nostru și al altora privind analiza miARN este lipsa metodelor standardizate de măsurare a nivelurilor absolute de miARN în plasmă, ceea ce face compararea cu alte date din literatură destul de dificilă.

Cel de al doilea studiu s-a ocupat de identificarea unor parametrii biochimici și epigenetici cu potențial de markeri ai gravității bolii arteriale periferice (BAP).

În studiul acesta, ne-am propus să identificăm modificări ale compoziției subfracțiilor HDL_2 și HDL_3 care se asociază cu severitatea BAP și determină alterarea funcției HDL măsurată ca efect anti-inflamator exercitat asupra CE umane activate cu TNFα. Un alt scop al studiului a fost de a determina care dintre modificările identificate la nivelul constituenților HDL sunt detectabile în plasmă și ar putea prezice severitatea bolii la pacienții cu BAP, pentru a fi transpuse în laboratoarele clinice.

Am analizat nivelurile unui set de 4 miARN-uri (hsa-miR-142-3p, hsa-miR-223-3p, hsa-miR-155-5p, hsa-miR-92a-3p) în plasma și în plăcile aterosclerotice femurale la pacienții cu BAP, care au dezvoltat evenimente cardiovasculare în decursul unui an de la intervenția chirurgicală primară. Am ales acest set de miARN pe baza studiilor anterioare din departamentul Lipidomică al IBPC-NS și al altor date publicate in literatură. Astfel, am analizat expresia din placă și de la nivel plasmatic al hsa-miR-142-3p, hsa-miR-223-3p, hsa-miR-155-5p, hsa-miR-92a-3p și am realizat corelații cu evoluția pacienților cu BAP. Am raportat că hsa-miR-142-3p poate fi considerat un biomarker predictiv pentru evenimentele cardiovasculare.

Studiul a cuprins 47 de pacienți diagnosticați cu BAP (4 femei și 43 de bărbați) BAP, cu vârste cuprinse între 32-83 de ani, cu by-pass la nivelul membrului inferior și 28 de subiecți sănătoși control (N). Am selecționat pacienții în funcție de criteriile de includere și excludere pe care le-am stabilit înainte de începerea studiilor, iar intervențiile chirurgicale au respectat recomandările societăților de profil.

Am determinat parametrii plasmatici, am izolat prin ultracentrifugare subfracțiile de HDL din plasma pacienților cu BAP, am măsurat parametrii biochimici în subfracțiile de HDL, am determinat aducții de proteine MDA și AGE în subfracțiile de HDL, am efectuat analiza Western blot și am analizat miARN în plasma și placa aterosclerotică de la pacienții cu BAP.

Pacienții cu BAP au fost împărțiți în două grupuri în funcție de prezența DZ ca patologie asociată cu BAP: (i) BAP fără DZ (BAP, n = 32) și (ii) BAP cunoscută a avea DZ (BAP-DZ, n = 21. HDL_2 și HDL_3 izolate prin ultracentrifugare din plasma subiecților sănătoși (N) și a pacienților BAP cu și fără DZ (BAP-DZ/BAP) au fost caracterizate prin:

1. conținutul de lipide și apolipoproteine: colesterol, fosfolipide (PL), apolipoproteina AI (ApoAI), ApoAII, ApoCIII, clusterin (CLU), and ApoE,
2. conținutul și activitatea PON1 și MPO: PON1 proteina și activitate, MPO proteina si activitate,
3. prezența aducților AGE-proteine: AGE-ApoAI, AGE-CLU, AGE-ApoE și AGE-PON1,
4. prezența markerilor de stres oxidativ: aducți malondialdehida-ApoAI (MDA-ApoAI), MDA-CLU, MDA-ApoE, MDA-PON1, ceruloplasmina (CP) și diene conjugate.

Rezultatele noi ale studiului nostru sunt că la pacienții cu BAP, DZ induce o alterare diferențiată a componentelor proteice ale HDL_2 și HDL_3, după cum urmează:

1. HDL_2 prezintă o reducere a proteinei PON1 și a activității, împreună cu scăderea apoAI și creșterea apoAII și apoCIII;
2. o creștere modestă a proteinei MPO în HDL_2 este însoțită de o creștere semnificativă a aducților de proteine-MDA și -AGE în ApoAI, CLU, ApoE și PON1;
3. în HDL_3 au crescut CLU și apoCIII și au scăzut nivelurile apoAII;
4. HDL_3 are o activitate PON1 redusă, în paralel cu nivelurile crescute de MPO și CP, și niveluri crescute de MDA- și AGE-PON1, -CLU și AGE-apoAI (Figurile 3-5)

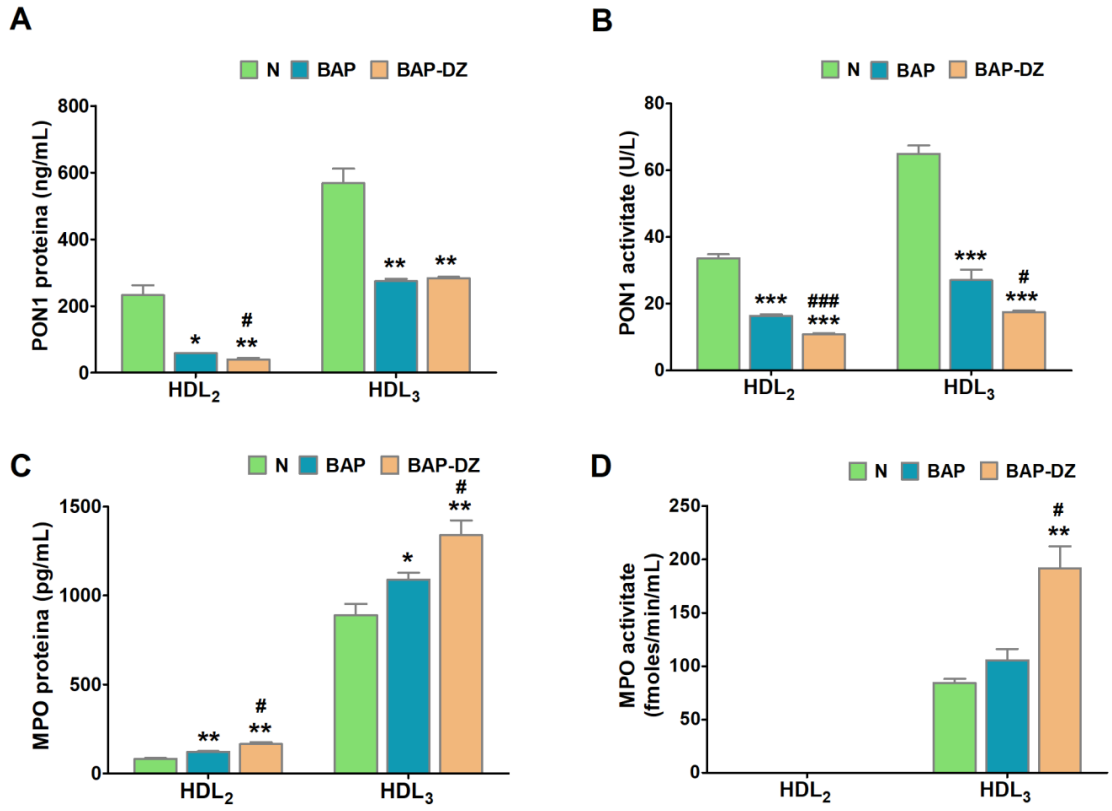

Figura 3. Nivelurile de proteină și activitate ale paraoxonazei 1 (PON1) si ale mieloperoxidazei (MPO) în subfracțiile de HDL. HDL_2 și HDL_3 izolate prin ultracentrifugare din plasma subiecților sănătoși (N) și a pacienților BAP cu și fără DZ (BAP-DZ/BAP) au fost caracterizate din punct de vedere al conținutului și activității PON1 și MPO: PON1 proteina (**A**) si activitate (**B**), MPO proteina (**C**) si activitate (**D**). Datele sunt exprimate ca medie ± SEM; *p < 0,05, **p < 0,01, ***p < 0,001 vs. N; $^{\#}$p < 0,05, $^{\#\#\#}$p < 0,001 vs. BAP.

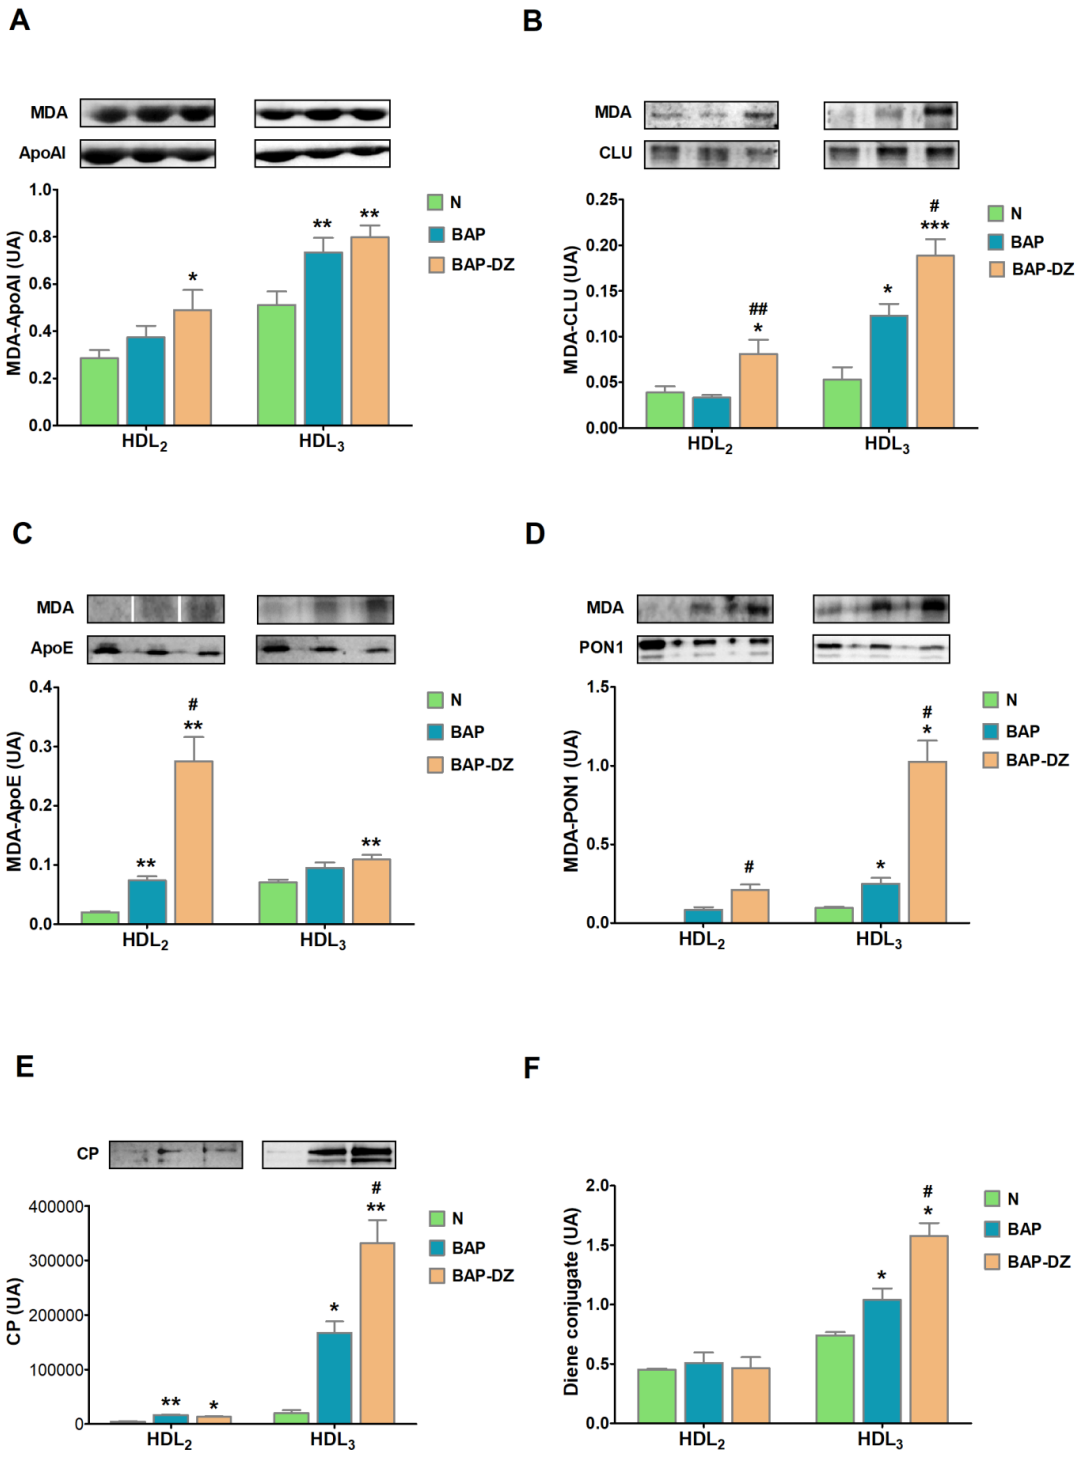

Figura 4. Parametrii de stres oxidativ în subfracțiile de HDL. HDL_2 si HDL_3 izolate prin ultracentrifugare din plasma subiecților sănătoși (N) și a pacienților BAP cu și fără DZ (BAP-DZ/BAP) au fost caracterizate din punct de vedere al prezenței markerilor de stres oxidativ: aducți malondialdehidă-apolipoprotein AI (MDA-ApoAI) (**A**), MDA-clusterina (MDA-CLU) (**B**), MDA-ApoE (**C**), MDA-paraoxonaza 1 (MDA-PON1) (**D**), ceruloplasmina (CP) (**E**) si diene conjugate (**F**). Datele sunt exprimate ca medie ± SEM; *p < 0,05, **p < 0,01, ***p < 0,001 vs. N; $^{\#}$p < 0,05, $^{\#\#}$p < 0,01 vs. BAP.

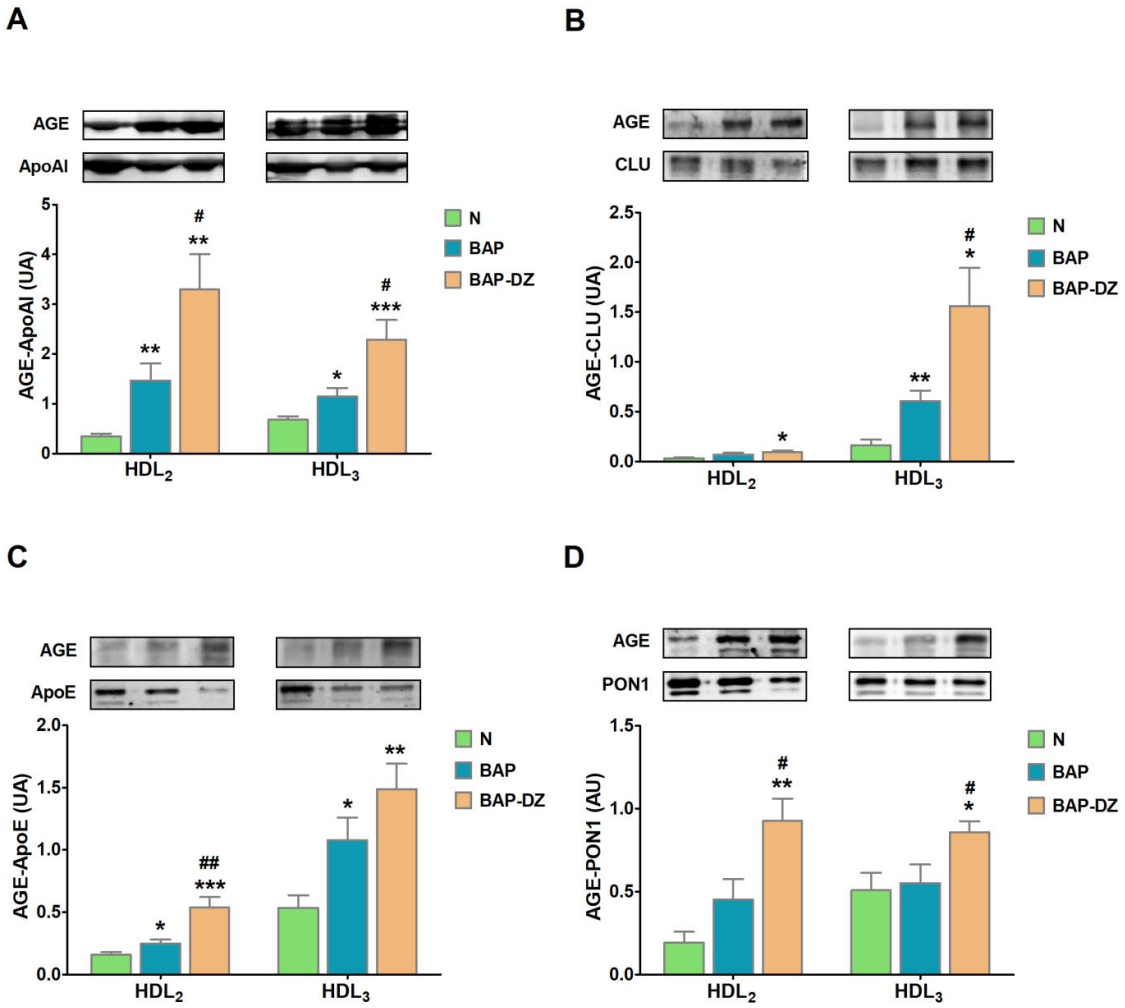

Figura 5. Produșii finali de glicare avansată (AGE) formează aducți cu proteinele din subfracțiile de HDL. HDL_2 și HDL_3 izolate prin ultracentrifugare din plasma subiecților sănătoși (N) și a pacienților BAP cu și fără DZ (BAP-DZ/BAP) au fost caracterizate din punct de vedere al prezenței aducților AGE-proteine: AGE-apolipoproteina AI (AGE-ApoAI) (**A**), AGE-clusterina (AGE-CLU) (**B**), AGE-ApoE (**C**) și AGE-paraoxonaza 1 (AGE-PON1) (**C**). Datele sunt exprimate ca medie ± SEM; *p < 0,05, **p < 0,01, ***p < 0,001 vs. N; $^{\#}$p < 0,05, $^{\#\#}$p < 0,01 vs. BAP.

În prezentul studiu, arătăm pentru prima dată că subfracțiile de HDL de la pacienții cu BAP și cu DZ au o compoziție distinctă în comparație cu cele de la pacienții cu BAP fără DZ. Astfel, HDL_2 are niveluri mai scăzute de TC și PL în BAP-DZ față de BAP.

O altă noutate a studiului nostru este redistribuirea CLU și apoAII între subfracțiile de HDL în BAP-DZ în comparație cu pacienții cu BAP. Astfel, nivelul CLU este redus în

HDL_2 și crescut în HDL_3, în timp ce nivelul apoAII este crescut în HDL_2 și diminuat în HDL_3 (Maskanakis et al., 2018, Rodriguez-Rivera et al., 2021). Rezultatele noastre arată că, în condiții patologice pronunțate, cum ar fi diabetul, producția de CLU este mai mare la pacienții cu BAP-DZ comparativ cu cei cu BAP, afinitatea sa pentru HDL_3 fiind crescută în comparație cu HDL_2, în acord cu datele publicate anterior (Davidson et al., 2009).

Raportăm aici pentru prima dată că la pacienții cu BAP-DZ versus cei cu BAP, proteina PON1 scade în HDL_2, în timp ce activitatea sa scade în ambele subfracții de HDL, probabil datorită creșterii semnificative a nivelurilor de MPO care dislocuie și oxidează PON1 (în special în HDL_3), contribuind astfel la disfuncția HDL. Anterior, raportul dintre proteinele MPO și PON1 sau dintre activitățile lor au fost propuse ca markeri pentru funcționalitatea HDL (Arora et al., 2016).

Datele noastre arată pentru prima dată că, în condiții diabetice, atașarea CLU la HDL_3 crește, în ciuda diminuării PON1. În plus, CP pro-oxidantă atașată la HDL_3 este crescută considerabil în condițiile diabetice, contribuind astfel la disfuncția HDL, în acord cu rezultatele noastre anterioare (Carnuta et al., 2017).

Astfel, o altă noutate a rezultatelor noastre este că CLU și CP sunt atașate la HDL_3 mai mult la pacienții cu BAP-DZ decât la cei cu BAP, sugerând că în condiții diabetice coexistența lor în HDL_3 este favorizată. Acest dezechilibru între enzimele antioxidante și pro-oxidante asociate cu HDL, în favoarea celor din urmă, generează o creștere semnificativă a modificărilor oxidative ale apolipoproteinelor. Toate aceste modificări sunt reflectate de nivelurile crescute de diene conjugate, MDA- și AGE-apolipoproteine și -PON1, dezvăluind o alterare excesivă a calității HDL la pacienții cu BAP-DZ comparativ cu cei cu BAP. Dintre modificările care apar în componentele HDL în condiții patologice, modificarea MDA-HDL are impactul negativ cel mai puternic asupra RCT (Bornfeldt et al., 2021).

Subliniem rezultatele noi și foarte interesante obținute în studiul nostru și anume că dintre toate componentele HDL_2 și HDL_3 analizate, doar nivelurile CLU, activitățile specifice PON1 și MPO prezintă diferențe semnificative în plasma pacienților cu BAP-DZ față de cei cu BAP și prezintă o puternică asociere predictivă cu diabetul. Numărul mic de pacienți cu BAP-DZ și BAP reprezintă o limitare a studiului nostru; totuși am ajuns la semnificație statistică pentru parametrii propuși ca markeri pentru severitatea BAP.

În **concluzie**, creșterea nivelurilor CLU și a activității specifice MPO și diminuarea activității specifice PON1 în plasmă reflectă alterarea funcționalității HDL. Acestea ar putea fi translatate în laboratoare clinice și ar putea prezice severitatea BAP în stările

hiperglicemice. În plus față de markerii stabiliți măsurați în laboratoarele clinice, acești trei parametri ar putea fi considerați biomarkeri candidați pentru severitatea BAP și utilizați în viitor pentru o predicție mai bună și mai timpurie a evoluției bolii.

Într-un studiu paralel am căutat să identificăm potențialii miARN predictivi pentru apariția evenimentelor cardiovasculare postoperatorii la pacienții cu BAP, măsurând nivelurile plasmatice ale miARN în plasmă și în placa aterosclerotică și am făcut corelații cu evenimentele cardiovasculare apărute pe parcursul unui an de la intervenția chirurgicală. Noile date (Figura 6) arată că spre deosebire de pacienții BAP fără EV, pacienții cu BAP cu EV prezintă:

1. o alterare a parametrilor asociați cu stresul oxidativ și inflamator, corelată cu o creștere semnificativă în plasmă a nivelurilor miR-142-3p și miR-223-3p;
2. creșteri semnificative ale expresiei miR-142-3p, miR-155-5p și miR-223-3p în placa aterosclerotică, care se corelează pozitiv cu nivelurile pri-miRNA asociate;
3. o scădere semnificativă a expresiei miR-92a în placă, în timp ce nivelul pri-miR-92a este crescut;
4. o asociere semnificativă între parametrii oxidativi și inflamatori, lipidele plasmatice și nivelul plasmatic al miARN ;
6. nivelul plasmatic al miR-142-3p s-a dovedit a fi un factor predictiv independent pentru evenimentele cardiovasculare la pacienții cu BAP.

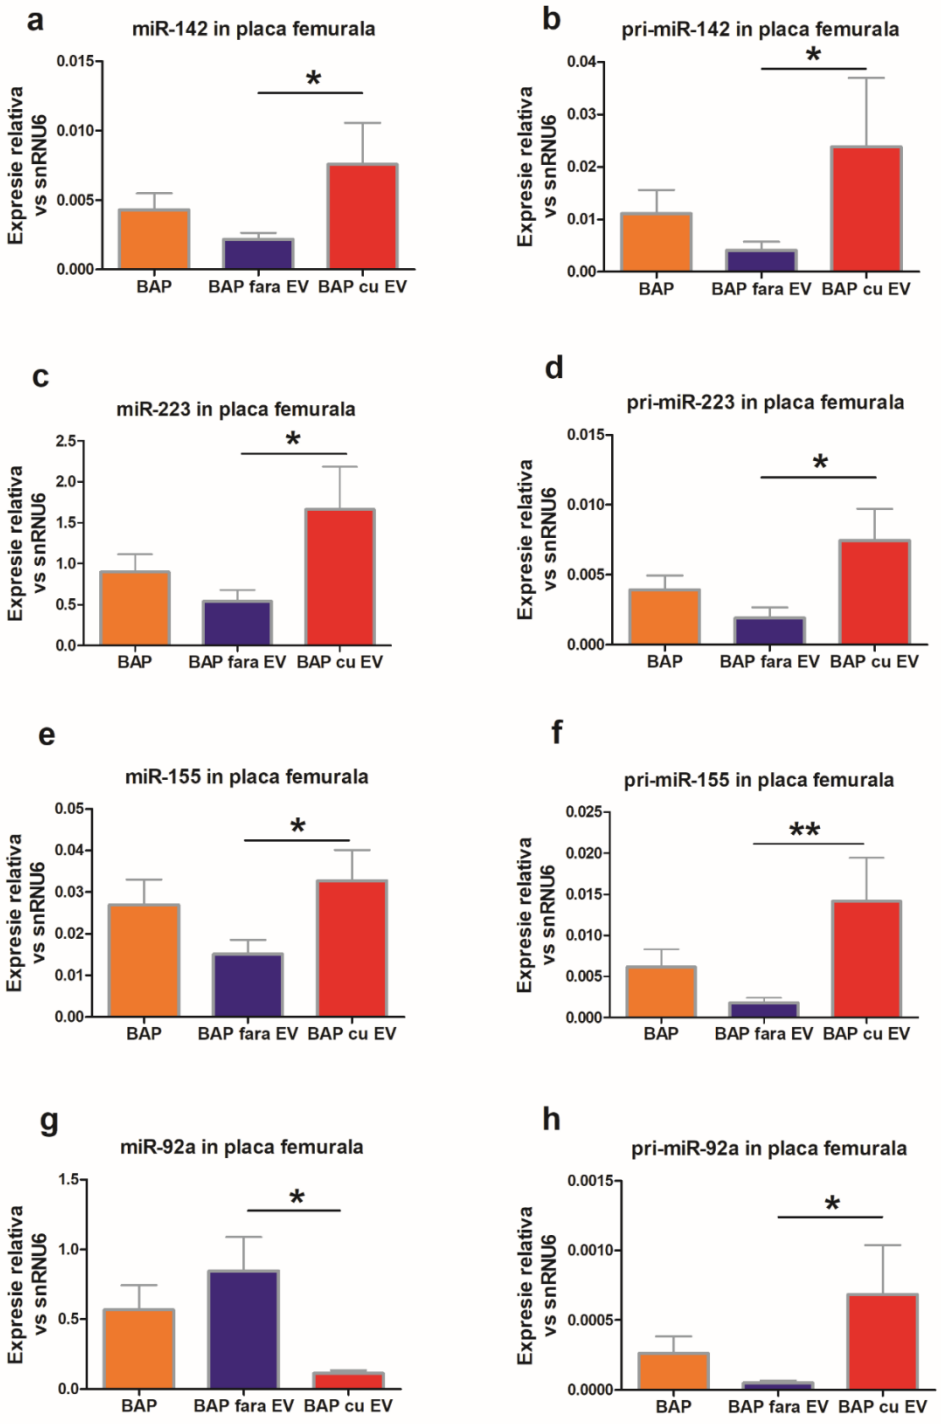

Figura 6. Nivelurile miARN și ale transcripților primari (pri-miARN) în plăcile aterosclerotice din arterele femurale de la pacienți cu boala arterelor periferice (BAP). Nivelurile miR-142 (**a**), miR-223 (**c**), miR-155 (**e**), miR-92a (**g**), pri-miR-142 (**b**), pri-miR-223 (**d**), pri-miR-155 (**f**), și pri-miR-92a (**h**) în plăci aterosclerotice femurale de la pacienți BAP cu evenimente cardiovasculare (BAP cu EV) post-operator comparativ cu cei fără EV (BAP fără EV). Datele sunt ilustrate ca histograme cu bară de eroare (SEM). Legenda: * valori $p < 0,05$, ** valori $p < 0,01$ comparativ cu BAP fără EV.

Din cunoștințele noastre, prezentul studiu este primul care abordează predicția evoluției bolii utilizând analiza comparativă a nivelului plasmatic și din placa de aterom a miARN la pacienții cu BAP. Am dovedit pentru prima dată legătura dintre nivelul miARN din placa aterosclerotică și expresia pri-miARN în placă.

Predicția precoce și rapidă a evoluției BAP poate optimiza decizia clinică pentru ajustarea intervențiilor individuale în cazul tratamentului acestor pacienți. Practicând o medicină personalizată, miR-142 poate contribui la stratificarea riscului pacienților cu BAP prezicând apariția evenimentelor cardiovasculare post-operator. Aceste noi date cresc posibilitatea utilizării terapiei având ca țintă miARN (inhibiția miR-142 in vivo) pentru a completa tratamentul cu statine în boala aterosclerotică, prin modularea mecanismului legat de miARN.

Cel mai important și nou rezultat al studiului este evidentierea potențialului miR-142 ca factor predictiv independent pentru apariția postoperator a evenimentelor cardiovasculare la pacienții cu BAP.

În concluzie, am demonstrat că miR-142-3p, miR-155-5p, miR-223-3p și miR-92a-3p sunt produși în placa aterosclerotică după cum se constată prin expresia specifică a pri-miARN și din corelațiile lor pozitive cu componentele cheie ale complexului de procesare miARN (enzimele Dicer și Drosha). De asemenea, am arătat că expresia miR-142-3p, miR-155-5p și miR-223-3p din placa aterosclerotică este asociată cu evenimentele cardiovasculare postoperatorii la pacienții cu BAP și corelate cu factorii de risc pro-aterogeni: metabolici, oxidativi și proinflamatorii. În final, bazat pe datele obținute din modelarea regresiei statistice, propunem miR-142-3p ca biomarker independent pentru prezicerea evenimentelor cardiovasculare la pacienții BAP.

Concluzii generale

1. Pacienții cu SAC prezintă alterarea parametrilor plasmatici asociați cu stresul oxidativ (scăderea PON1, creșterea MPO și CP) și inflamator (creșterea IL-1β și CRP) comparativ cu subiecții sănătoși.
2. Pacienții cu SAC având vârsta peste 65 de ani prezintă o creștere semnificativă a nivelurilor miR-223-3p atât în plasmă, cât și în placa de aterom carotidiană, comparativ cu pacienții cu SAC având vârsta sub 65 de ani.
3. Nivelul crescut de miR-223-3p în placa de aterom carotidiană la pacienții cu SAC cu vârsta peste 65 de ani este asociat cu o expresie crescută a pri-miR-223 din placa aterosclerotică.
4. Diabetul zaharat de tip II induce o alterare diferențiată a componentelor proteice ale subfractiilor HDL_2 și HDL_3 în plasma pacienților cu BAP, după cum urmează:

- HDL_2 prezintă o reducere atât a proteinei cât și a activității enzimatice a PON1, împreună cu scăderea apoAI și creșterea apoAII și apoCIII; nivelul proteinei MPO prezinta o creștere modestă.
- HDL_3 are o activitate enzimatica a PON1 redusă, în paralel cu nivelurile crescute de MPO și CP, asociate cu nivelurile crescute de MDA- și AGE-PON1, MDA- și AGE-CLU și AGE-apoAI.

5. Modificarea concentrațiilor plasmatice ale unor proteine alterate în HDL, precum CLU, PON1 și MPO, ar putea fi considerate indicatori ai severității bolii la pacienții cu BAP.
6. MiR-142 are potențialul de a fi considerat un factor predictiv independent pentru apariția postoperatorie a evenimentelor cardiovasculare la pacienții cu BAP.
7. Din punctul de vedere al chirurgului vascular, accesul la măsurarea nivelului miARN la pacienții cu SAC ar permite indicarea de măsuri timpurii de evaluarea a stării pacienților prin monitorizare ecografică la termen mai scurt pentru descoperirea restenozei la pacienții cu SAC operați și aplicarea tratamentului corespunzător.
8. Compoziția și funcția HDL sunt modificate la pacienții cu BAP și intr-un grad mai mare la pacienții BAP cu diabet zaharat de tip II. Nivelurile modificate ale CLU și ale activităților specifice ale PON1 și MPO sunt detectabile în plasma pacienților cu BAP. Întrucât izolarea și caracterizarea HDL este o procedură laborioasă, putem considera nivelurile plasmatice ale CLU, PON1 si MPO drept indicatori potențiali ai disfuncției HDL care pot fi utilizați pentru o mai bună stratificare a riscului la pacienții cu BAP.

REZUMATUL TEZEI DE DOCTORAT

cu titlul

Identificarea de noi biomarkeri epigenetici utilizabili pentru creşterea preciziei în predicţia evoluţiei bolii aterosclerotice

Conducator de doctorat
Acad. Maya Simionescu

Doctorand
Teodora Barbălată

2024

Cuprins

Cuvânt înainte....1

Listă abrevieri....3

Introducere şi obiectivele generale ale tezei....6

A. STADIUL ACTUAL AL CUNOAŞTERII....8

1. Sistemul cardiovascular în condiţii fiziologice şi patologice....8

Inima, artere coronare, artere periferice: structură şi funcţie....8

Structura peretelui arterial în condiţii fiziologice şi modificări în ateroscleroză....9

2. Metabolismul lipoproteinelor....16

Principalele clase de lipoproteine circulante şi proprietăţile lor....16

Lipoproteinele de înaltă densitate (HDL) – rol în condiţii fiziologice şi în ateroscleroză. 18

3. Epigenetica şi bolile cardiovasculare - moleculele de ARN necodant şi de ADN extracelular 24

Moleculele mici de ARN necodant – microARN....25

Moleculele mari de ARN necodant – long non-coding ARN....28

Moleculele de ADN circulante în plasmă – ADN extracelular (ADNcf) şi ADN mitocondrial (ADNmt) 31

4. Editarea genică prin tehnologia *CRISPR/dCas9* – o metodă de a corecta sinteza de HDL disfuncţional 33

Editarea genică – o nouă tehnologie de tratament a bolilor cardiovasculare....33

A. CONTRIBUŢII ORIGINALE....37

Studii preclinice *in vitro* şi *in vivo*....37

Obiectivul I. Hiperlipidemia: caracterizarea HDL disfuncţional şi distribuţia plasmatica a microARN; efectul unor tratamente hipolipemiante....37

Proiect I. 1. Hiperlipemia determină sinteza de HDL disfuncţional şi reducerea efluxului de colesterol la nivelul intestinului subţire la hamsterul hiperlipidemic; efectele benefice ale extractului de ghimbir în această patologie....37

Introducere şi obiective....37

Protocoale experimentale şi metode de analiză....39

Rezultate....45

Caracterizarea extractului de ghimbir....45

Extractul de ghimbir crește raportul HDL-C/colesterol total și diminuează stresul oxidativ în plasma hamsterilor hiperlipidemici....45

Extractul de ghimbir modulează expresia moleculelor componente ale HDL în intestinul subțire (apoA-I, PON1, MPO și ABCA1)....47

Extractul de ghimbir stimulează efluxul trans-intestinal de colesterol....49

Extractul de ghimbir restabilește expresia genică și proteică a factorilor de transcriere LXRα/β și PPARγ, precum și a modulatorilor acestora SIRT1 și TTC39B în intestinul subțire.....49

Extractul de ghimbir diminuează depozitele de lipide din valvele aortice.....51

Discuţii şi concluzii parţiale.....52

Proiect I. 2. Modularea microARN-urilor plasmatice în hamsterii hiperlipidemici prin administrarea probioticelor sau stoparea dietei grase.....56

Introducere şi obiective.....56

Protocoale experimentale şi metode de analiză.....57

Rezultate.....61

Nivelurile de lipide în serul și ficatul hamsterilor hiperlipidemici sunt reduse prin oprirea administrării dietei grase sau administrarea probioticelor simultan cu dieta grasă.....61

Nivelurile de microARN (miR-223-3p, miR-122-5p, miR-92a-3p și miR-486-5p) din serul și ficatul hamsterilor hiperlipidemici sunt scăzute atât de administrarea probioticelor simultan cu dieta grasă, cât și de oprirea administrării dietei grase.....63

Oprirea administrării dietei grase modulează expresia hepatică a unor gene implicate în reglarea metabolismului lipidic: HMGCS1, HMGCR, SR-BI și LDLR.....65

Discuţii şi concluzii parţiale.....67

Proiect I. 3. Reglarea nivelurilor microARN în hiperlipidemia indusă de dieta grasă la hamster 72

Introducere şi obiective.....72

Protocoale experimentale şi metode de analiză.....73

Rezultate.....76

Profilele de expresie ale miARN în plasma hamsterului hiperlipidemic.....76

Validarea miARN-urilor selectate în ficat și miocard prin qPCR.....78

Analiza funcțională – procesele biologice în care sunt implicate cele 3 miARN.....80

Discuţii şi concluzii parţiale.....82

Proiect I.4 Activarea transcripțională a apolipoproteinei A-I şi a paraoxonazei 1 din enterocite prin tehnologia CRISPR/dCas9; efectul benefic asupra celulelor endoteliale disfuncţionale86

Introducere şi obiective.....86

Protocoale experimentale şi metode de analiză.....88

Rezultate.....92

Activarea transcripțională a *ApoAI* endogenă prin tehnologia CRISPR/dCas9 în enterocite umane în cultură.....92

Activarea transcripțională a PON1 endogenă prin tehnologia CRISPR/dCas9 în enterocite umane în cultură.....93

Efectul supraexprimării *ApoA-I* și *PON1* endogene asupra expresiei proteice a receptorului SR-BI și a transportorilor ABCA1 și ABCG8 în enterocite umane în cultură.....94

Efectul supraexprimării *ApoA-I* și *PON1* endogene asupra expresiei proteice a factorilor de transcriere PPARγ, LXRs și SIRT1 implicați în reglarea metabolismului lipidic în enterocite umane în cultură.....95

Efectul mediului condiționat colectat de la enterocite Caco-2 care supraexprimă *ApoAI* și *PON1* endogene asupra celulelor endoteliale activate cu TNFα.....95

Discuţii şi concluzii parţiale.....97

Studii efectuate pe material uman obţinut de la pacienţi cu boli cardiovasculare.....103

Obiectivul II. Rolul clusterinei, al paraoxonazei 1 şi al mieloperoxodazei în disfuncţia HDL şi contribuţia la boala arterelor periferice; agravarea de către diabetul de tip 2.....103

Introducere şi obiective.....103

Protocoale experimentale şi metode de analiză.....104

Rezultate.....108

Caracteristicile clinice și parametrii biochimici ai pacienților PAD.....108

Parametri lipidici plasmatici.....109

Markeri ai stresului oxidativ în plasma pacienților PAD.....110

Corelații între nivelurile plasmatice de CLU, activitățile specifice ale PON1 și MPO, și hiperglicemie la pacienții PAD.....111

Caracterizarea fracțiilor HDL_2 și HDL_3 izolate de la pacienții PAD.....113

Potențialul anti-inflamator al subfracției HDL_3 la pacienții PAD-DM comparativ cu pacienții PAD 118

Discuţii şi concluzii parţiale.....120

Obiectivul III. Studii epigenetice (miR-142-3p, miR-223-3p; LIPCAR, MALAT1) la pacienţii cu boala arterelor periferice, stenoza arterelor carotide, infarct de miocard sau boala arterelor coronare 124

Proiect III. 1. Asocierea dintre nivelul crescut de miR-142 din plasma şi plăcile aterosclerotice ale pacienţilor cu boala arterelor periferice şi evoluţia post-operatorie a acestora.....124

Introducere şi obiective.....124

Protocoale experimentale şi metode de analiză.....126

Rezultate.....129

Principalii parametri plasmatici ai pacienților PAD.....129

Expresia miARN, pri-miARN și ARNm în plăcile de aterom colectate de la nivelul arterei femurale la pacienții PAD.....130

Nivelurile miARN în plasma pacienților PAD.....133

Asocierea între nivelurile plasmatice ale miARN și ECV post-operatorii ale pacienților PAD 136

Analiza funcțională – analiza Gene Ontology pentru identificarea proceselor biologice în care sunt implicate cele 4 miARN.....138

Discuţii şi concluzii parţiale.....141

Proiect III. 2. Determinarea nivelului miR-223-3p din plasma şi placa de aterom ale pacienţilor în vârstă cu stenoza arterelor carotide; asocierea cu proteine implicate în metabolismul HDL 145

Introducere şi obiective.....145

Protocoale experimentale şi metode de analiză.....146

Rezultate.....149

Principalii parametri plasmatici ai pacienților CAS.....149
Nivelurile pri-miR-223 în placi și nivelurile miR-223-3p în plăcile și plasma pacienților CAS 151
Expresia ARNm a moleculelor de interes în plăcile de aterom ale pacienților CAS....151
Corelațiile între parametri măsurați în plăcile de aterom și diverși parametri plasmatici ai pacienților CAS.....153
Asocierea nivelurilor plasmatice ale miR-223-3p cu vârsta pacienților CAS.....157
Discuţii şi concluzii parţiale.....158
Proiect III. 3. Evaluarea capacităţii ADN mitocondrial şi hsa-miR-142-3p de predicţie a evoluţiei pacienţilor după un infarct miocardic acut.....162
Introducere şi obiective.....162
Protocoale experimentale şi metode de analiză.....163
Rezultate.....167
Parametri plasmatici ai pacienților STEMI și variația lor la 6 luni post-infarct.....167
Nivelurile plasmatice ale ADNcf și ADNmt la pacienții STEMI și variația lor la 6 luni post-infarct 173
Corelații între nivelurile plasmatice ale miARN, ADNcf, ADNmt și principalii parametri plasmatici ai pacienților STEMI.....174
Asocierea parametrilor clinici cu MACE la 6 luni post-infarct.....175
Parametri plasmatici asociați cu MACE produse în timpul celor 6 luni de urmărire. .177
Asocierea nivelurilor ciculante ale microARN cu MACE produse în timpul celor 6 luni de monitorizare 180
Asocierea dintre nivelurile ADNcf și ADN mt și MACE produse în timpul celor 6 luni de monitorizare 181
Asocierile statistice între parametri plasmatici și cardiaci și ulterioarele MACE la pacienții STEMI 182
Nivelurile microARN selectate, ADNcf și ADNmt – ca predictori ai ulterioarelor MACE la pacienții STEMI.....186
Discuţii şi concluzii parţiale.....190
Proiect III.4. Analiza lncARN LIPCAR şi MALAT1 circulante şi corelarea cu evoluţia pacienţilor cu sindrom coronarian acut.....194
Introducere şi obiective.....194
Protocoale experimentale şi metode de analiză.....196
Rezultate.....199
Parametri biochimici ai pacienților SA, UA și STEMI.....199
Distribuția ARNnc în plasma pacienților SA, UA și STEMI.....201
Corelații între ARNlnc, miARN și principalii parametri biochimici în plasma pacienților BAC 203

Postere prezentate la manifestări ştiinţifice internaţionale – 6

Specializări şi cursuri efectuate – 4

Premii – 2

Participarea în proiecte de cercetare – 7

În **prima parte** a lucrării de doctorat am descris pe scurt aspecte teoretice legate de sistemul cardiovascular atât în condiţii fiziologice, cât şi patologice, în special legate de iniţierea formării şi progresia plăcii aterosclerotice. De asemenea, sunt menţionate aspecte cu privire la metabolismul lipoproteinelor circulante, cu precădere particulele de HDL, precum şi aspecte despre biologia moleculelor de ARN necodante. Bolile cardiovasculare (BCV) rămân principala cauză de morbiditate şi mortalitate la nivel mondial, în ciuda progresului tehnologic şi medical. La baza acestor boli stă ateroscleroza, o patologie multifactorială inflamatorie cronică care afectează arterele medii şi mari din diverse paturi vasculare (Schaftenaar et al. 2016). Ateroscleroza presupune proliferarea matricei extracelulare a celulelor rezidente din peretele arterial, acumularea de lipide şi calciu la acest nivel, adeziunea monocitelor şi plachetelor circulante la nivelul endoteliului, un proces care declanşează o cascadă de modificări moleculare şi structurale care, în cele din urmă, conduc la obstrucţia circulaţiei sangvine la nivelul vasului afectat (Libby et al. 2011).

În prezent, există o serie de parametri utilizaţi în practica medicală care furnizează informaţii cu privire la riscul pe care pacienţii îl prezintă în ceea ce priveşte dezvoltarea de boli cardiovasculare. Printre aceşti parametri se numără nivelurile crescute de colesterol total, de colesterol de la nivelul lipoproteinelor de joasă densitate (LDL-C) sau nivelurile scăzute de colesterol din lipoproteinele de înaltă densitate (HDL-C), însă acestea nu sunt în totalitate suficiente pentru a indica pacienţii aflaţi la risc. Din acest motiv există încă o nevoie urgentă de a identifica noi parametri sensibili, specifici şi precişi care să vină în completarea celor enumeraţi mai sus. În acest context, se face remarcată o serie de molecule de natură epigenetică, de tipul microARN-urilor (Vogiatzi et al. 2018) sau al ARN-urilor necodante lungi (Holdt et al. 2010), care sunt promiţătoare în ceea ce priveşte atât diagnosticul, cât şi prognosticul timpuriu al evoluţiei bolii la pacienţii cardiovasculari.

Epigenetica studiază totalitatea modificărilor care apar la nivelul materialului genetic, modificări care nu sunt moştenite, ci dobândite ca urmare a impactului pe care îl au factorii externi asupra materialului genetic. O direcţie de cercetare a epigeneticii vizează moleculele de ARN necodante (ARNnc), care, prin funcţiile pe care le îndeplinesc în celulă, au indirect efect asupra expresiei genice şi, deci asupra ADN.

Este cunoscut faptul că doar 2% din genomul uman codifică proteine, în timp ce restul a fost, până recent, considerat material genetic redundant, fără importanţă biologică, aşa numitul „*junk DNA*”. Ultimele două decenii de cercetări în domeniul genomicii şi transcriptomicii au contrazis această idee şi

au demonstrat faptul că regiunile ADN care nu codifică proteine, transcrise în transcripţi de ARN necodant, au un rol crucial în menţinerea homeostaziei celulare.

Prin termenul „ARN necodant" (ARNnc) înţelegem totalitatea tipurilor de molecule de ARN diferite de ARN codant, şi anume ARN mesager (ARNm).

ARNnc se împart, în funcţie de mărime, în două categorii principale:

- ARN necodante de dimensiune mică (<200 nucleotide) –microARN (miARN), ARN mic de interferenţă (ARNsi) sau ARN de interferenţă piwi (ARNpi);
- ARN necodante de dimensiune mare (>200 nucleotide) –ARN necodante lungi (ARNlnc), ARN circulare (ARNcirc) sau ARN de tip *enhancer* (ARNe) (Zhang et al. 2019).

Moleculele de **miARN** sunt molecule de ARN necodant înalt conservate, cu o dimensiune de aproximativ 20 de nucleotide, înscriindu-se astfel în categoria ARN necodante reglatoare de dimensiuni mici. Acestea sunt implicate în reglajul expresiei genice, prin faptul că se leagă şi blochează moleculele de ARNm.

Cu toate că această categorie de molecule a fost observată iniţial în studiul cancerului, ulterior a fost demonstrată implicarea lor şi în numeroase alte patologii, cum ar fi diabetul, bolile auto-imune sau afecţiunile cardiovasculare. Datorită posibilităţii de a fi măsurate cu uşurinţă în circulaţie sau in probe de ţesut, precum şi datorită stabilităţii lor ridicate, miARN au devenit rapid candidaţi pentru a servi drept biomarkeri pentru diversele patologii. În ceea ce priveşte BCV, există diverse miARN care au fost propuse ca markeri, cum ar fi miR-133 pentru insuficienţa cardiacă sau miR-21 pentru fibroza cardiacă şi ateroscleroză (Barwari et al. 2016). De asemenea, într-un studiu desfăşurat în laboratorul nostru, colegii au demonstrat că miR-486 şi miR-92a au potenţialul de a discrimina între pacienţii cu boala arterelor coronare (BAC) vulnerabilă faţă de cei stabili (Niculescu et al. 2015).

O a doua categorie de ARN necodant care pare să prezinte potenţial prognostic sau diagnostic pentru diverse patolgii, şi care în ultimii ani a primit o atenţie deosebită sunt ARN-urile necodante lungi (**lncARN**). Acestea au o lungime de peste 200 de nucleotide şi sunt implicate într-o multitudine de procese biologice, cum sunt ciclul celular, diferenţierea celulară, precum şi în diverse patologii (Bridges et al. 2021). Studiile arată că lncARN prezintă niveluri de expresie mai scăzute decât ARNm sau miARN, dar prezintă şi specificitate tisulară mai crescută, ceea ce le recomandă ca markeri ai diverselor patologii. O altă deosebire constă în gradul scăzut de conservare al lncARN între specii, deşi aceasta nu e o regulă generală (Johnsson et al. 2014).

Pentru a îndeplini obiectivele propuse în prezenta teză de doctorat am utilizat tehnici de biologie moleculară, biochimie şi culturi celulare, care au fost descrise în secţiunile „Protocoale experimentale şi metode de analiză" ale fiecărui studiu. În experimentele desfăşurate pe perioada programului doctoral, am pus la punct metodele de cuantificare a long non-coding ARN, precum şi a ADN circulant extracelular (ADNcf) din plasma pacienţilor prin Real-Time PCR.

Cea de-**a doua parte** a tezei de doctorat cuprinde contribuţiile originale aduse în domeniul de cercetare şi este structurată în două capitole principale, care cuprind în total 9 studii (vezi Cuprinsul).

Principalele rezultate ale primelor 4 **studii preclinice *in vitro* şi *in vivo*** (primul capitol) sunt următoarele:

(i) Hiperlipidemia determină producţia de HDL disfuncţional şi diminuează astfel efluxul de colesterol la nivelul intestinului subţire în hamsterul hiperlipidemic. Extractul de ghimbir are capacitatea de a reversa şi îmbunătăţi aceste procese, contribuind la homeostazia metabolismului lipidic. Rezultatele prezentate în acest studiu au fost publicate în articolul cu titlul: **Hyperlipidemia Determines Dysfunctional HDL Production and Impedes Cholesterol Efflux in the Small Intestine: Alleviation by Ginger Extract**, autori: **Teodora Barbălată**, Mariana Deleanu, Mihaela Georgiana Cărnuţă, Loredan Ştefan Niculescu, Mina Răileanu, Anca Volumnia Sima, Camelia Sorina Stancu. publicat în revista *Molecular Nutrition and Food Research* **2019**, 63(19) :e1900029. DOI: 10.1002/mnfr.201900029. **Factor de impact la momentul publicării (2019): 5,309 (Q1)**; factor de impact în 2022: 5,2 (Q1).

(ii) Administrarea probioticelor sau oprirea dietei grase la hamsterii hiperlipidemici au ca efect scăderea nivelurilor serice şi hepatice ale miR-223-3p, miR-122a-5p, miR-92a-3p şi miR-486-5p. Rezultatele obţinute în cadrul acestui studiu au fost publicate în articolul cu titlul: **Probiotics administration or the high-fat diet arrest modulates microRNAs levels in hyperlipidemic hamsters,** autori: Loredan S. Niculescu, Mădălina D. Dulceanu, Camelia S. Stancu, Mihaela G. Cărnuţă, **Teodora Barbălată**, Anca V. Sima, în revista *Journal of Functional Foods* **2019**, 56, 295-302, DOI 10.1016/j.jff.2019.03.036. **Factorul de impact al revistei în anul publicării (2019): 3,701 (Q1)**, iar în 2022: 5,6 (Q1).

(iii) Hiperlipidemia indusă prin administrarea unei diete grase are ca efect creşterea nivelurilor miR-146a-5p, miR-21-5p, miR-223-3p în miocardul, ficatul, şi intestinul subţire ale hamsterilor hiperlipidemici. Rezultatele obţinute în cadrul acestui studiu au fost publicate în

articolul cu titlul **Regulation of microRNAs in high-fat diet induced hyperlipidemic hamsters,** autori **Teodora Barbălată**, Lu Zhang, Mădălina D. Dulceanu, Camelia S. Stancu, Yvan Devaux, Anca V. Sima, Loredan S. Niculescu, în revista *Scientific Reports* **2020**, 10: 20549, DOI 10.1038/s41598-020-77539-4. **Factorul de impact al revistei în anul publicării (2020): 4,38 (Q1),** iar în anul 2022: 4,6 (Q2).

(iv) Activarea transcripţională a apolipoproteinei A-I şi a paraoxonazei 1 utilizand editarea genică prin tehnologia CRISPR/dCas9 în enterocite umane în cultură îmbunătăţeşte calitatea HDL disfuncţional. De asemenea, mediul condiţionat colectat de la enterocitele transfectate are un efectul benefic asupra celulelor endoteliale disfuncţionale. Rezultatele prezentate în acest studiu au fost publicate în articolul cu titlul **CRISPR/dCas9 Transcriptional Activation of Endogenous Apolipoprotein AI and Paraoxonase 1 in Enterocytes Alleviates Endothelial Cell Dysfunction**, autori: Laura Toma, Teodora Barbălată, Gabriela M. Sanda, Loredan S. Niculescu, Anca V. Sima, Camelia S. Stancu, publicat în revista *Biomolecules* **2021**, 11, 1769. DOI: 10.3390/biom11121769. **Factor de impact la momentul publicării (2021): 6,064 (Q2)**; factor de impact în 2022: 5,5 (Q1).

Principalele rezultate ale celor 5 studii cuprinse în cel de-al doilea capitol cuprinde **studii efectuate pe material uman obţinut de la pacienţi cu boli cardiovasculare**:

(i) Disfuncţia HDL este caracterizată de nivelurile crescute ale clusterinei şi ale mieloperoxidazei, precum şi de nivelurile scăzute ale paraoxonazei 1 la pacienţii cu boala arterelor periferice (PAD – peripheral artery disease), iar aceste modificări sunt agravate de prezenţa diabetului de tip 2. Datele obţinute în cadrul acestui studiu au fost publicate în articolul cu titlul **Clusterin, paraoxonase 1, and myeloperoxidase alterations induce high-density lipoproteins dysfunction and contribute to peripheral artery disease; aggravation by type 2 diabetes mellitus**, autori: Gabriela M. Sanda, Laura Toma, **Teodora Barbălată**, Oriana E. Moraru, Loredan S. Niculescu, Anca V. Sima, Camelia S. Stancu în revista *BioFactors* **2021**: 1-15, DOI 10.1002/biof.1800. **Factorul de impact al revistei în anul publicării (2021): 6,438 (Q1)**, iar în anul 2022: 6,0 (Q1).

(ii) Nivelurile plasmatice ale miR-142-3p sunt crescute la pacienţii PAD, precum şi în plăcile de aterom izolate de la aceştia, ceea ce recomandă acet miARN ca posibil biomarker pentru evoluţia post-operatorie nefavorabilă a pacienţilor. Rezultatele obţinute în acest capitol au fost publicate în articolul cu titlul **Increased miR-142 Levels in Plasma and**

Atherosclerotic Plaques from Peripheral Artery Disease Patients with Post-Surgery Cardiovascular Events, autori: **Teodora Barbălată,** Oriana E. Moraru, Camelia S. Stancu, Yvan Devaux, Maya Simionescu, Anca V. Sima, Loredan S. Niculescu, în revista *International Journal of Molecular Sciences* **2020**, 21: 9600, DOI: 10.3390/ijms21249600. **Factorul de impact al revistei în anul publicării (2020): 5,92 (Q1),**.

(iii) Nivelurile crescute ale miR-223-3p din plasmă şi plăcile de aterom de la pacienţii cu stenoza arterelor carotide (CAS) sunt corelate cu vârtsa înaintată a pacienţilor şi cu proteine implicate în metabolismul HDL. Rezultatele obţinute în acest capitol au fost publicate în articolul cu titlul **MiR-223-3p levels in the plasma and atherosclerotic plaques are increased in aged patients with carotid artery stenosis; association with HDL-related proteins,** autori: **Teodora Barbălată**, Oriana E. Moraru, Camelia S. Stancu, Anca V. Sima, Loredan S. Niculescu, în revista *Molecular Biology Reports* **2021**, DOI: 10.1007/s11033-021-06636-y. **Factorul de impact al revistei în anul publicării (2021): 2,742 (Q4)**

(iv) Nivelurile plasmatice crescute ale ADN mitocondrial şi miR-142-3p sunt un indicator al evoluţiei nefavoraile a pacienţilor după un infarct miocardic cu supradenivelare de segment ST (STEMI). Rezultatele obţinute în acest capitol au fost publicate în 2 articole: primul articol are titlul **Mitochondrial DNA Together with miR-142-3p in Plasma Can Predict Unfavorable Outcomes in Patients after Acute Myocardial Infarction,** autori: **Teodora Barbălată**, Alina I. Scărlătescu, Gabriela M. Sanda, Laura Toma, Camelia S. Stancu, Maria Dorobanţu, Miruna M. Micheu, Anca V. Sima, Loredan S. Niculescu, în revista *International Journal of Molecular Sciences* **2022***, 23: 9947*, DOI: 10.3390/ijms23179947. **Factorul de impact al revistei în anul publicării (2022): 5,6 (Q1)**; cel de-al doilea articol cuprinde parţial rezultate din acest capitol al tezei şi are titlul **miR-146a-5p, miR-223-3p and miR-142-3p as Potential Predictors of Major Adverse Cardiac Events in Young Patients with Acute ST Elevation Myocardial Infarction—Added Value over Left Ventricular Myocardial Work Indices**, autori: Alina Ioana Scărlătescu, **Teodora Barbălată**, Anca Volumnia Sima, Camelia Stancu, Loredan Ştefan Niculescu, Miruna Mihaela Micheu, în revista *Diagnostics (Basel)*, **2022** 12(8):1946, DOI: 10.3390/diagnostics12081946. **Factorul de impact al revistei în anul publicării (2022): 3,6 (Q2).**

(v) Evoluția nefavorabilă a pacienților cu sindrom coronarian acut se corelează cu nivelurile circulante crescute ale ARNlnc LIPCAR şi MALAT1, ceea ce recomandă aceste două ARNlnc ca posibili biomarkeri pentru evoluția pacienților. Rezultatele obținute în acest capitol au fost publicate într-un articol cu titlul **Elevated Levels of Circulating lncRNAs LIPCAR and MALAT1 Predict an Unfavorable Outcome in Acute Coronary Syndrome Patients**, autori: **Teodora Barbălată**, Loredan S. Niculescu, Camelia S. Stancu, Florence Pinet, Anca V. Sima, în revista *International Journal of Molecular Sciences* 2023, 24(15):12076, DOI: 10.3390/ijms241512076. **Factorul de impact al revistei în 2022: 5,6 (Q1).**

Printre cele mai relevante rezultate obținute în urma studiilor realizate pentru prezenta teză se numără următoarele:

Studiul care a analizat asocierea dintre nivelul crescut de miR-142 din plasma şi plăcile aterosclerotice ale pacienților cu boala arterelor periferice (PAD) şi evoluția post-operatorie a acestora a relevat că în comparație cu pacienții PAD fără eventimente cardiovasculare ulterioare (fără ECV), pacienții PAD cu ECV au prezentat niveluri crescute ale miR-142-3p, miR-223-3p şi miR-155-5p în plăcile aterosclerotice, rezultate care s-au corelat pozitiv cu nivelurile transcripților primari ai miARN (pri-miARN) (Figura 1). De asemenea, prezența pri-miARN la nivelul plăcilor de aterom PAD, corelată cu prezența ARNm pentru Drosha şi Dicer la acest nivel, indică posibila sinteză locală a miARN de interes în plăci. Analiza statistică (Tabelul 1) a rezulatelor obținute în acest studiu, sugerează că miR-142-3p circulant prezintă potențialul de a fi predictor independent pentru producerea de ECV post-operatorii la pacienții PAD.

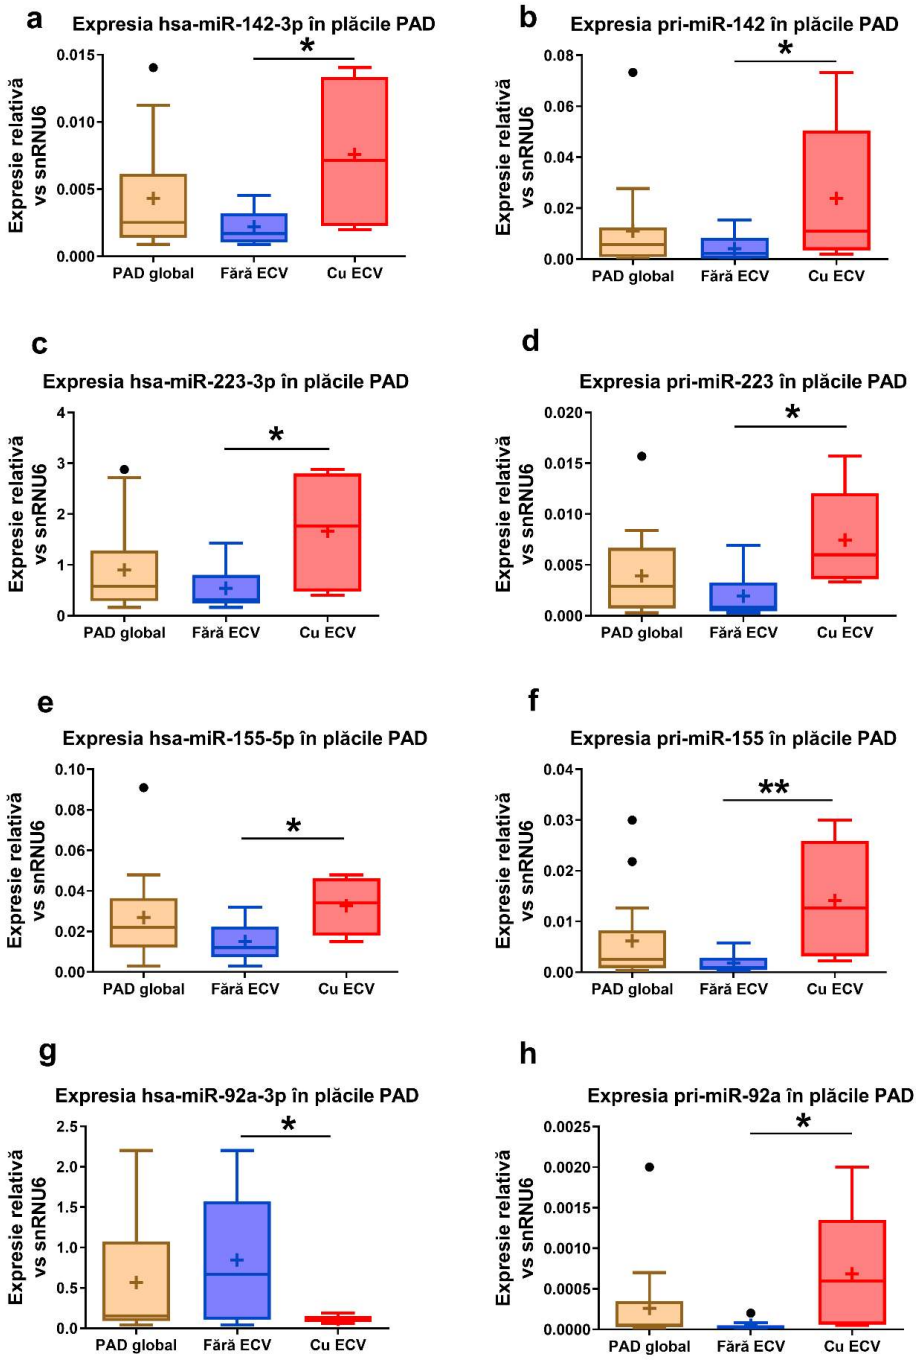

Figura 1. Nivelurile miARN şi ale transcripţilor lor primari (pri-miARN) în plăcile aterosclerotice recoltate de la pacienţii PAD. Nivelurile miR-142 (a), miR-223 (c), miR-155 (e), miR-92a (g), pri-miR-142 (b), pri-miR-223 (d), pri-miR-155 (f) şi pri-miR-92a (h) în plăcile aterosclerotice ale pacienţilor PAD cu ECV comparativ cu cei fără ECV. Datele sunt ilustrate ca boxplot-uri cu Tukey whiskers, linia reprezintă mediana, iar semnul plus (+) reprezintă media. *p<0,05, **p<0,01 vs ”fără ECV”

Principalele rezultate ale studiul în care am analizat potenţialul de predicţie al evenimentelor cardiovasculare majore (MACE) la pacienţii STEMI al unor noi markeri, cum sunt ARNnc extracelulare (miARN) sau ADN extracelular (ADNcf) şi ADN mitocondrial (ADNmt) circulante sunt: pacienţii STEMI prezintă următoarele modificări în momentul externării din spital (T_1) comparativ cu momentul internării (T_0): (i) niveluri crescute ale tuturor celor 6 miARN analizate (hsa-miR-223-3p, hsa-miR-142-3p, hsa-miR-155-5p, hsa-miR-486-5p, hsa-miR-125a-5p şi hsa-miR-146a-5p); (ii) niveluri plasmatice crescute ale ADNcf şi ADNmt. Totodată, comparativ cu pacienţii STEMI fără MACE, cei cu MACE au prezentat: (i) niveluri crescute ale tuturor celor 6 miARN analizate (hsa-miR-223-3p, hsa-miR-142-3p, hsa-miR-155-5p, hsa-miR-486-5p, hsa-miR-125a-5p şi hsa-miR-146a-5p) (Figura 2); (ii) niveluri crescute ale ADNcf şi ADNmt (Figura 3). În urma analizei statistice BLR şi ROC, am raportat pentru prima dată că nivelurile plasmatice ale ADNmt împreună cu cele ale miR-142-3p pot prezice cu acurateţe evoluţia nefavorabilă a pacienţilor STEMI (Tabel 2).

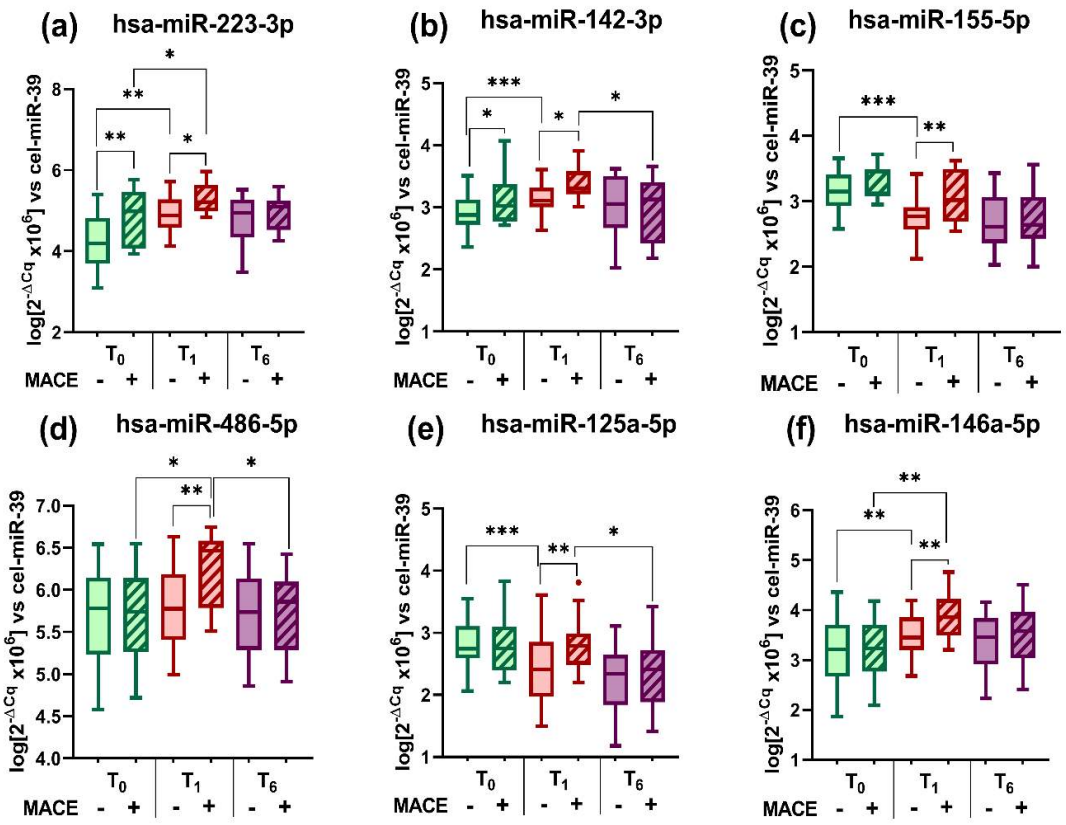

Figura 2. Variaţia miARN (a-f) în plasma pacienţilor STEMI la momentele T_0, T_1 şi T_6 grupaţi în funcţie de incidenţa MACE în timpul celor 6 luni de monitorizare. Datele sunt ilustrate ca boxplot-uri cu Tukey whiskers, linia orizontală reprezintă mediana. *p<0,05; **p<0,01; ***p<0,001.

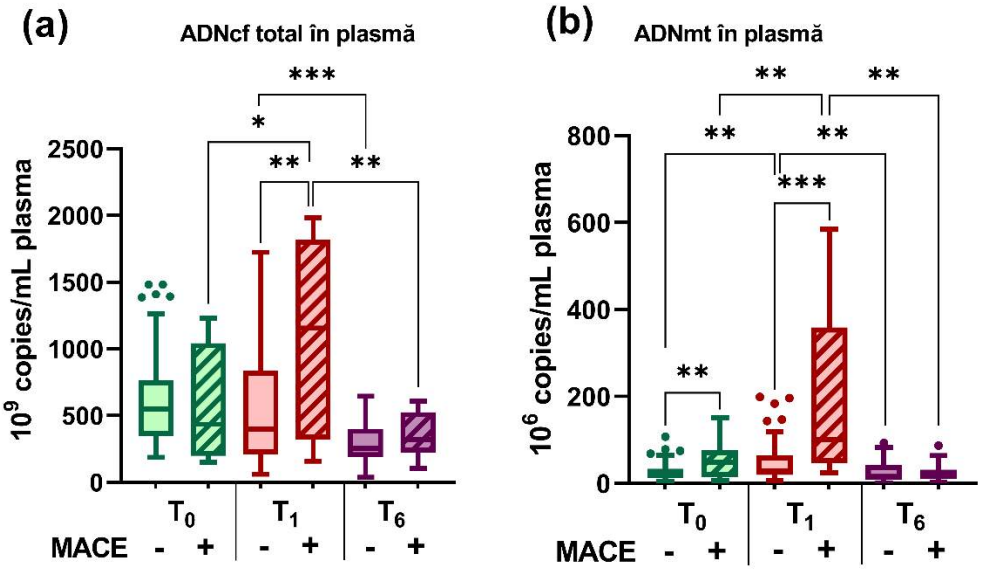

Figura 3. Variaţia ADNcf total (a) şi a ADNmt (b) în plasma pacienţilor STEMI la momentele T_0, T_1 şi T_6 grupaţi în funcţie de incidenţa MACE în timpul celor 6 luni de monitorizare. Datele sunt ilustrate ca boxplot-uri cu Tukey whiskers, linia orizontală reprezintă mediana. *p<0,05; **p<0,01; ***p<0,001.

Tabelul 3. Analiza ROC pentru determinarea potenţialului predictiv al modelelor uni sau multivariate pentru MACE la pacienţii STEMI, utilizând valorile plasmatice ale miARN, ale ADNcf şi ale ADNmt determinate în momentul externării din spital (T_1).

În urma studiului care a vizat investigarea potenţialului de discriminare al pacienţilor cu sindrom coronarian acut (ACS) la risc pentru ARNlnc LIPCAR şi MALAT1, precum şi a două miARN relevante, am concluzionat următoarele că la pacienţii cu angină stabilă (SA) şi angină instabilă (UA): (i) nivelurile LIPCAR, MALAT1, hsa-miR-155-5p şi hsa-miR-142-3p sunt semnificativ crescute în plasma pacienţilor cu BAC vulnerabili (UA) comparativ cu cei stabili (SA); (ii) nivelurile LIPCAR, MALAT1 şi miR-142-3p sunt semnificativ crescute la pacienţii UA hiperglicemici (UA-HG) comparativ cu cei normoglicemic (NG), în timp ce miR-142-3p a prezentat valori crescute şi la pacienţii SA-HG vs SA-NG (Figura 4); (iii) modelul minimal ROC multivariat care poate discrimina pacienţii cu boala arterelor coronare vulnerabili este alcătuit din LIPCAR şi MALAT, cu o uşoară îmbunătăţire în urma adăugării miR-155-5p (Tabelul 3).

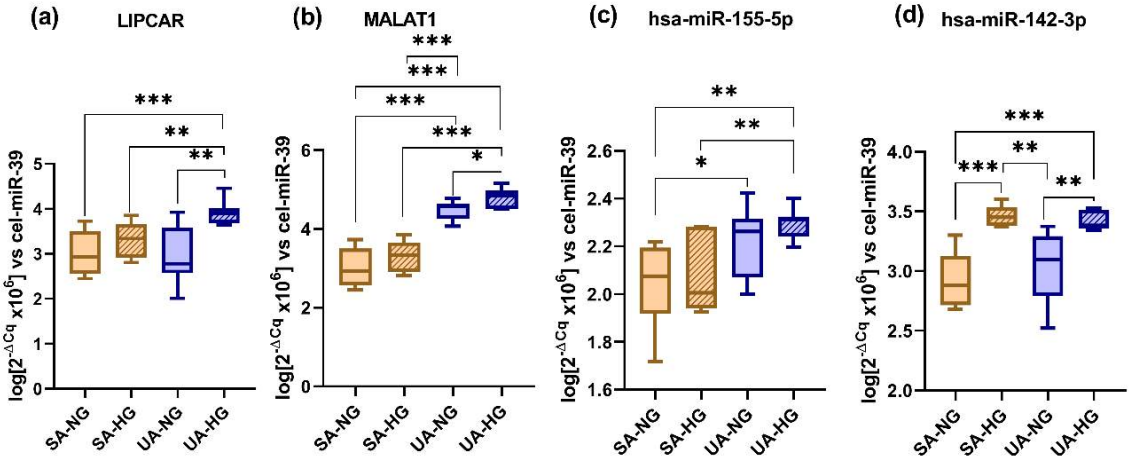

Figura 4. Nivelurile ARNnc în plasma pacienţilor SA şi UA hiperglicemici (HG) comparativ cu cei normoglicemici (NG): LIPCAR (a), MALAT1 (b), miR-155-5p (c) şi miR-142-3p (d). Datele sunt ilustrate ca boxplot-uri cu Tukey whiskers, linia orizontală reprezintă mediana. *p<0,05; **p<0,01; ***p<0,001.

Tabelul 3. Analiza ROC pentru determinarea potenţialului de discriminare al modelelor uni- şi multivariate pentru diagnosticul ACS – UA versus SA, utilizând ARNlnc LIPCAR şi MALAT1 şi miARN hsa-miR-155-5p şi hsa-miR-142-3p

Modelul multivariat 2 (LIPCAR, MALAT1 şi miR-155-5p)	0.938	0.047	4.08×10^{-4}	0.846	1.000
Modelul multivariat 3 (LIPCAR, MALAT1 şi miR-142-3p)	0.836	0.081	5.92×10^{-3}	0.677	0.994
* Ajustate pentru vârstă şi sex (masculin ca risc). A. În condiţii nonparametrice. B. Ipoteza de nul: true area = 0.5.					

În concluzie, studiile pe care le-am desfăşurat pe perioada programului doctoral şi care au avut ca scop comun identificarea de noi biomarkeri epigenetici care să contribuie la creşterea acurateţei prognosticului bolii cardiovasculare au condus la identificarea unor molecule de tipul microARN şi lncARN care sunt utile în acest sens. Astfel, s-au remarcat miR-142-3p, LIPCAR şi MALAT1.

Rezultatatele obţinute în aceste studii încurajează investigarea mecanismelor moleculare în care sunt implicate şi pe care le modulează aceste molecule de ARN necodante, precum şi validarea lor ca biomarkeri ai diverselor boli cardiovasculare pe cohorte mai mari de pacienţii. Aceste perspective deschise de rezulatele cercetării pot veni în sprijinul introducerii lor în practica medicală curentă şi a atingerii principalului scop al medicinii moderne, şi anume medicina personalizată.

Premii câştigate

1. **Premiul "Best Poster Award"** pentru lucrarea: **Barbalata T**, Oriana E. Moraru, Loredan S. Niculescu, Camelia S. Stancu, Maya Simionescu, Anca V. Sima. A panel of circulating miRNAs could predict age-related post-endarterectomy cardiovascular events in carotid artery stenosis patients. Prezentare în cadrul celei de-a 4-a Întâlniri "MC and WG Meeting of COST Action

CA17129 “Catalysing transcriptomics research in cardiovascular disease”. 12-14 Februarie 2020, Maastricht, Olanda.

2. **Premiul pentru cel mai bun poster** pentru lucrarea: **Barbalata T**., Niculescu L.S., Stancu C.S., Pinet F., Sima A.V. LIPCAR and MALAT1, two long non-coding RNAs, are increased in the plasma acute coronary syndrome patients and predict major adverse cardiovascular events. Conferința Societății Române de Biologie Celulară (SRBC), 16-17 Noiembrie 2023, București, România.

Comunicări orale susținute la manifestări științifice internaționale: 5 comunicări

1. **Barbălată Teodora**. Prezentare orală în cadrul Simpozionului Internațional Acad. N. Cajal. Hyperlipidemia induces the production of dysfunctional HDL in the small intestine and liver of hamsters, and increases hepatic lipid-related miRNAs. 17-19 Octombrie **2019**, București, România.
2. **Barbălată Teodora**. Prezentare orală în cadrul Conferinței online CardioRNA Live! a acțiunii COST CA17129 “Catalysing transcriptomics research in cardiovascular disease”. A panel of miRNAs and inflammatory markers are associated with hyperglycemia in peripheral artery diseases patients. 7-10 Septembrie **2020**.
3. **Barbălată Teodora**. Prezentare orală în cadrul Conferinței Societății Române de Biologie Celulară (SRBC). MicroRNAs profiling in the heart and liver of high-fat diet induced hyperlipidemic hamster. 4-6 Noimebrie **2021,** București, România
4. **Barbălată Teodora**. Prezentare orală în cadrul “8th MC and WG Meeting of COST Action CA17129 “Catalysing transcriptomics research in cardiovascular disease”. Analysis of long non-coding RNAs (LIPCAR) distribution in human blood compartments. 25-27 Mai **2022**, Pavia. Italia
5. **Barbălată Teodora.** Prezentare orală în cadrul Simpozionului Științific Anual „Institute of Cellular Biology and Pathology Nicolae Simionescu. Increased plasma levels of miR-142-3p and mitochondrial DNA predict unfavorable outcomes in patients after acute myocardial infarction. 8-9 Decembrie **2022**, București, România.

Brevete înregistrate

Aplicație de patent nr. a 2022 00502, cu data de depozit la Oficiul de Stat pentru Invenții și Mărci (OSIM) 18/08/2022 și titlul “Fitozomi cu compuși biologic activi din rizomi de ghimbir și fructe de măceș cu biodisponibilitate crescută și procedeu de obținere”, autori: Deleanu M., Toma L., Sanda G.M., Niculescu L.S., **Barbalata T.**, Suciu A., Alexandru G., Crisan I., Popescu M., Stancu C.S.

COLABORĂRI ÎN PROIECTE DE CERCETARE

CUPRINS

LISTA ABREVIERILOR 1

INTRODUCERE ȘI OBIECTIVELE GENERALE ALE TEZEI 3

PARTEA I- STADIUL ACTUAL AL CUNOȘTINȚELOR 6

I.1. CELULELE STROMALE MEZENCHIMALE DERIVATE DIN MADUVĂ OSOASĂ ȘI ȚESUT ADIPOS, ȘI IMPLICAREA ACESTORA ÎN REGENERAREA CUTANATĂ 6

I.1.1. Caracteristicile celulelor stromale mezenchimale derivate din maduvă osoasă și țesut adipos 6

I.1.2. Potentialul terapeutic al celulelor stromale mezenchimale derivate din maduvă osoasă și țesut adipos 8

I.2. PROCESUL DE VINDECARE AL RĂNILOR CUTANATE 14

I.2.1. Structura pielii 14

I.2.2. Etapele vindecarii rănilor cutanate 25

I.3. APLICAŢIILE NANOPARTICULELOR ŞI BIOMATERIALELOR ÎN REGENERAREA TISULARĂ 31

I.3.1. Nanoparticule pe bază de fier 31

I.3.2. Nanoparticule pe bază de argint 35

I.3.3. Substituenți cutanați pe bază de biomateriale 40

I.4. CONTRIBUȚIA SECRETOMULUI CELULELOR STROMALE MEZENCHIMALE ADULTE ÎN REGENERAREA CUTANATĂ 47

I.5. EXOSOMII SECRETAȚI DE CELULELE STROMALE MEZENCHIMALE DERIVATE DIN MADUVĂ OSOASĂ ȘI ȚESUT ADIPOS PENTRU REGENERAREA CUTANATĂ 51

I.5.1. Biogeneza și compoziția exosomilor 53

I.5.2. Metode de izolare a exosomilor 57

I.5.3. Tehnici de cuantificare și caracterizare a exosomilor 61

I.5.4. Efectele exosomilor secretați de celule stromale mezenchimale asupra procesului de vindecare a rănilor cutanate 64

PARTEA A II-A: CONTRIBUȚII ORIGINALE 75

II.1. POTENŢIALUL TERAPEUTIC AL NANOPARTICULELOR PE BAZĂ DE FIER CA VECTORI PENTRU ELIBERAREA CONTROLATĂ DE PRINCIPII ACTIVE 75

II.1.1. Introducere şi obiective 75

II.1.2. Materiale şi metode 76

II.1.2.1. Sinteza şi caracterizarea fizico-chimică a nanoparticulelor hibride Fe-PEI 76
II.1.2.2. Linii celulare 78
II.1.2.3. Coloraţia Albastru de Prusia pentru evidențierea fierului 78
II.1.2.4. Interacțiunea NP Fe-PEI marcate fluorescent cu MSC 79
II.1.2.5. Imagistică de bioluminiscență pe celule în cultură 79
II.1.2.6. Microscopia electronică de trasmisie (TEM) 80
II.1.2.7. Măsurarea potențialului membranar mitocondrial (ΔΨm) 80
II.1.2.8. Determinarea dimensiunii agregatelor de nanoporticule 80
II.1.2.9. Evaluarea biocompatibilității NP Fe PEI cu aparatul xCellIgence 81
II.1.2.10. Testul de hemoliză 81
II.1.2.11. Evaluarea *in vivo* pe un model de xenografă heterotopică de glioblastom pe șoareci imunodeficienți 81
II.1.3. Rezultate 82
II.1.3.1. Selecția și caracterizarea fizico-chimică a NP Fe-PEI 82
II.1.3.2. Agregarea NP Fe-PEI în mediul de cultură 86
II.1.3.3. NP Fe-PEI cu DiI încorporat în timpul agregării sunt capabile să elibereze fluorocromul prin contact direct cu celulele 88
II.1.3.4. NP Fe-PEI cu substante încorporate în timpul agregarii sunt capabile sa le elibereze prin contact direct cu celulele 90
II.1.3.5. Încorporarea de cisplatină în NP Fe-PEI în timpul sintezei hidrotermale este asociată cu o eficienţă crescută a medicamentului 91
II.1.4. Discutii şi concluzii parţiale 96
II.2. POTENŢIALUL SECRETOMULUI DERIVAT DIN CELULE STROMALE MEZENCHIMALE UMANE ÎN VEDEREA DEZVOLTĂRII DE TERAPII PENTRU VINDECAREA RĂNILOR CUTANATE 99
II.2.1. Introducere şi obiective 99
II.2.2. Materiale şi metode 99
II.2.2.1. Sinteza şi caracterizarea matricei de colagen tridimensionale 99
II.2.2.2. Tehnici de culturi celulare 100
II.2.2.3. Caracterizarea MSC prin citometrie de flux 101
II.3.2.4. Caracterizarea fibroblastelor dermale umane prin imunocitochimie 101
II.2.2.5. Evaluarea capacităţii matricelor de colagen de a fi colonizate cu keratinocite şi fibroblaste umane 101

II.2.2.6. Evaluarea calitativă a viabilităţii keratinocitelor şi fibroblastelor umane cultivate pe matrici de colagen 102

II.2.2.7. Evaluarea efectului secretomului asupra aderării şi proliferarii keratinocitelor şi fibroblastelor umane cultivate în sistem 2D şi pe matricile 3D de colagen 102

II.2.2.8. Evaluarea capacităţii de migrare prin metoda "scratch test" 103

II.2.2.9. Evaluarea expresiei genice folosind tehnica PCR cantitativ în timp real (qPCR) 103

II.2.2.10 Testarea efectului chemo-atractant al secretomului 104

II.2.2.11. Evaluarea profilului citokinelor de la nivelul secretomului 104

II.2.2.11. Analiza statistică 104

II.2.3. Rezultate 105

II.2.3.1. Caracterizarea MSC derivate din maduvă osoasă şi a fibroblastelor izolate din derm 105

II.2.3.2. Matricea de colagen poroasă permite colonizarea cu keratinocite și fibroblaste 106

II.2.3.3. Secretomul influențează proprietățile keratinocitelor și fibroblastelor în sistemul clasic 2D de cultură 110

II.2.3.4. Secretomul promovează colonizarea matricelor de colagen cu keratinocite și fibroblaste 114

II.2.3.5. Secretomul prezintă proprietăți pro-angiogene și conține factori mito- și motogeni, precum și modulatori ai angiogenezei 118

II.2.4. Discutii şi concluzii parţiale 120

II.3. POTENȚIALUL TERAPEUTIC AL NANOPARTICULELOR PE BAZĂ DE ARGINT (NP AG) PENTRU TRATAMENTUL RĂNILOR CUTANATE 123

II.3.1. Introducere și obiective 123

II.3.2. Materiale și metode 123

II.3.2.1. Sinteza și caracterizarea fizico-chimică a nanoparticulelor hibride pe bază de argint 123

II.3.2.2. Linii celulare 124

II.3.2.3. Evaluarea viabilităţii celulare 124

II.3.2.4. Evaluarea capacităţii de migrare prin metoda "scratch test" 125

II.3.2.5. Evaluarea efectului apoptotic indus de NP Ag 125

II.3.2.6. Marcare fluorescentă a actinei filamentoase 125

II.3.2.7. Formarea de tubi pe GELTREX 125

II.3.2.8. Testarea microbiologică- metoda microdiluţiilor binare în bulion 126

II.3.3. Rezultate 126

II.3.3.1. Caracterizarea fizico-chimică a NP Ag 126

II.3.3.2. Evaluarea citotoxicității NP Ag pe keratinocite, fibroblaste şi celule endoteliale 128

II.3.3.3. Evaluarea efectelor NP Ag asupra migrării keratinocitelor, fibroblastelor şi celulelor endoteliale 133

II.3.3.4. Evaluarea efectelor NP Ag asupra citoscheletului actinic de la nivelul keratinocitelor, fibroblastelor şi celulelor endoteliale 136

II.3.3.5. Evaluarea efectelor NP Ag asupra procesului de angiogeneză 139

II.3.3.6. Evaluarea efectelor antibacteriene ale NP Ag 141

II.3.4. Discuții și concluzii parțiale 141

II.4. EVALUAREA EFECTELOR EXOSOMILOR ELIBERAŢI DE CELULE STROMALE MEZENCHIMALE ASUPRA CELULELOR PIELII, ÎN VEDEREA DEZVOLTĂRII UNUI TRATAMENT PENTRU VINDECAREA RĂNILOR CUTANATE 145

II.4.1. Introducere şi obiective 145

II.4.2. Materiale și metode 146

Introducere și obiectivele generale ale tezei

Medicină regenerativă, reprezintă una din ramurile medicinei dezvoltate în vederea îmbunătățirii calității vieții pacienților. Conform unei definiții din 2006, acest domeniu interdisciplinar utilizează diverse abordări tehnologice cum ar fi: administrarea de molecule solubile, terapia genică, transplantul de celule stem, reprogramarea celulară și mai ales, ingineria tisulară [Greenwood et al. 2006]. Johnson et al au efectuat o analiză a categoriile de activități privind cele mai bune abordări din domeniu, concluzionând că este necesară înțelegerea și controlul angiogenezei, alături de răspunsul imun al organismului, a comportamentului celulelor stem și standardizarea utilizării acestora, precum și capacitatea de producerea în masă a construcților de inginerie tisulară rezultați [Johnson et al. 2007]. Astfel, sinergia unor discipline de bază cum ar fi: biologia celulară și știință materialelor au generat sisteme complexe tri-dimensionale (3D) celule-biomaterial, implantatabile cu scopul de a regenera țesutul, dar și sisteme exclusiv celulare, cum ar fi transplantul de celulele stem, sau bazate exclusiv pe biomateriale, care în urmă implantării se integrează la nivelul organismului [Muzzio et al. 2021].

Unul din principalii piloni care au susținut dezvoltarea domeniului medicinei regenerative, inclusiv a ingineriei tisulare, a fost stabilit acum mai bine de 50 de ani, când Friedenstein et al. au raportat izolarea unei populații clonogene, multipotente, fibroblastoide, derivate din măduvă osoasă [Friedenstein et al. 1968]. Ulterior, aceste celule stromale mezenchimale (MSC), considerate celule multipotente ușor accesibile, au fost izolate din diverse țesuturi umane adulte cum ar fi țesut adipos, sau prenatale: cordon umbilical, fluid amniotic. MSC au fost evaluate în studii clinice sub formă de terapie celulară pentru diferite patologii: precum infarctul miocardic acut, scleroza multiplă sau forma acută a bolii grefă versus gazdă rezistentă la steroizi [NCT00877903, NCT02239393, NCT02923375]. În ciuda potențialului de diferențiere observat *in vitro*, efectele benefice obținute în urma administrării de MSC nu au fost asociate cu grefarea acestor celule sau modificarea fenotipului către unul specific țesutului țintit. Mai mult, deși studiile preclinice au evidențiat rezultate promițătoare, efectele terapeutice nu au fost reproduse și în cadrul studiilor clinice; de altfel, în Europa prima autorizație de punere pe piață pentru un produs pe bază de MSC, s-a obținut abia în 2018 [Galipeau și Sensebe, 2018]. În același timp, secretomul MSC, constituit din totalitatea factorilor solubili (chemokine, citokine, factori de creștere) și veziculele extracelulare (microvesicule, exosomi) eliberate în mediul extracelular, s-a evidentiat ca efector paracrin pentru acțiunea benefică observată în cazul administrării acestor celule, conturându-se astfel o nouă abordare terapeutică „cell-free" [Praveen Kumar et al. 2019].

Pe de altă parte, domeniul științei materialelor s-a axat pe dezvoltarea unor compuși care să fie complementari acțiunii MSC. Mai exact, pornind de la matricea extracelulară ca model pentru fabricarea biomaterialelor, s-au propus diverși suporți tridimensionali („scaffolds") care să sprijine proliferarea și diferențierea celulelor cu scopul de a promova regenerarea tisulară. În general, pentru țesuturile moi s-au utilizat polimeri precum colagenul, alginatul, proteoglicanii,

chitosanul, datorită biocompatibilității și acțiunii bioactive ce permite aderarea și creșterea celulelor la nivelul lor. Totodată, domeniul nanomaterialelor a contribuit la dezvoltarea domeniului medicinei regenerative, mai exact prin varietatea nanoparticulelor (NP) ce pot fi utilizate fie ca vectori pentru eliberarea de principii active, fie ca agenți antibacterieni care să asigure siguranța utilizării biomaterialelor, prevenind infecțiile locale [Hasan et al. 2018].

În lucrarea de față au fost propuse următoarele obiective:

1. evaluarea unor nanoparticule superparamagnetice pe bază de fier și polietilenimina (NP Fe-PEI) obținute printr-o metodă de sinteză blândă, care să permită simultan încorporarea de agenți terapeutici cu prezervarea acțiunii lor, în scopul de a valida utilizarea acestor nanoparticule ca vectori pentru eliberarea de principii active;
2. investigarea capacității secretomului celulelor stromale mezenchimale umane, de a îmbunătăți performanțele *in vitro* ale unei matrice de colagen poroase utilizate în vindecarea rănilor cutanate;
3. selecția unor nanoparticule cu efecte antibacteriene pe bază de argint și polimeri, în funcție de acțiunea lor biologică asupra principalelor tipuri celulare implicate în vindecarea leziunilor pielii: keratinocite, fibroblaste dermale și celule endoteliale;
4. selecția exosomilor secretați de MSC izolate din două surse: măduva osoasă și țesut adipos, în vederea validării acestora *in vitro* ca agenți terapeutici activi capabili să stimuleze regenerarea cutanată prin acțiunea lor asupra principalelor etape din vindecarea rănilor cutanate.

Structura tezei de doctorat

Lucrarea este structurată în doua părți: **prima parte-** Stadiul actual al cunoștințelor- divizat în cinci capitole ce prezintă principalele caracteristici ale celulelor stromale mezenchimale și potențialul lor terapeutic, structura pielii şi etapele vindecării leziunilor cutanate, urmate de aspecte legate de aplicațiile nanoparticulelor, biomaterialelor precum și a secretomului pentru regenerarea cutanată. Ultimul capitol este dedicat exosomilor, conținând aspecte generale privind originea, izolarea și caracterizarea acestora, concentrându-se apoi pe cei secretați de MSC ca agenți terapeutici pentru vindecarea rănilor pielii**. Partea a doua** a lucrării include contribuțiile originale, organizate în patru capitole, corespunzătoare studiilor desfășurate pentru atingerea obiectivelor tezei.

Primul studiu- *Potenţialul terapeutic al nanoparticulelor pe bază de fier ca vectori pentru eliberarea controlată de principii active*, a presupus investigarea biocompatibilitatii unor nanoparticule superparamagnetice hibride pe baza de fier si polietilenimina (NP Fe-PEI) atât pe celule umane normale cât și tumorale, a capacității acestor nanoparticule de a încorpora principii active în urmă agregării în mediu de cultură și ulterior de a elibera substanță prin contact cu

celulele, precum și a efectului anti-tumoral al nanoparticulelor Fe-PEI cu cisplatina încorporată în timpul sintezei hidrotermale, pe modele *in vitro* și *in vivo.*

Principalele rezultate originale (Fig. 1):

1. nanoparticulele hibride cu un raport masic Fe:PEI de 1:2 obținute prin sinteză hidrotermală la 100 atm și 40°C și resuspendate într-o soluție de NaCl în prezența de PAA (acid poliacrilic) pentru stabilizare, au fost asociate cu o lipsă de toxicitate pe celulele stromale mezenchimale (MSC) murine la aceleași concentrații însă manifestând un efect citotoxic pe celulele tumorale de glioblastom (linia U87);

2. nanoparticulele hibride Fe:PEI au agregat spontan în mediu de cultură, iar agregatele astfel formate au încorporat substanțe active (DiI, valinomicina) prezente în soluție, pe care apoi le-au eliberat prin contact direct cu celula, activitatea biologică a substanțelor fiind prezervată;

3. nanoparticulele hibride Fe-PEI cu cisplatină încorporată în timpul sintezei au prezentat o acțiune anti-tumorală mai puternică comparativ cu medicamentul administrat ca atare la aceeași concentrație sau cu nanoparticulele cu cisplatina adăugată după sinteză atât *in vitro* pe linia U87 cât și *in vivo* pe modelul murin de xenografă heterotopică de glioblastom.

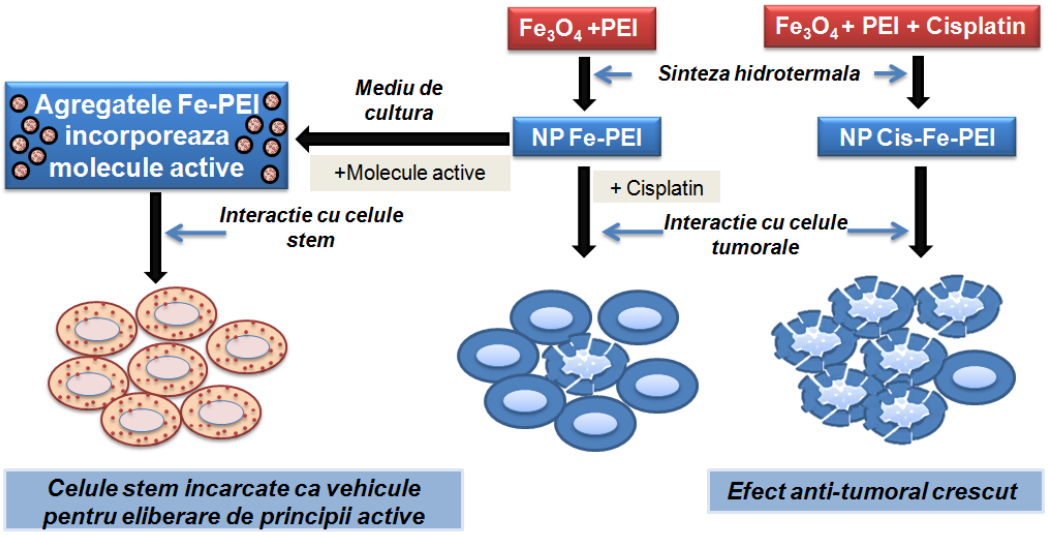

Figura 1. Reprezentare schematică sumarizând rezultatele prezentate în primul studiu privind potențialul terapeutic al nanoparticulelor hibride Fe-PEI. Rezultatele prezentate în acest capitol indică faptul că NP Fe-PEI au încorporat molecule active prin incubarea în mediu de cultură, şi au eliberat ulterior aceste substanţe prin contact direct cu celulele stem mezenchimale. De asemenea, nanoparticulele cu cisplatină încorporată în timpul sintezei, au prezentat un efect

anti-tumoral mult mai puternic comparativ cu nanoparticulele la care s-a adăugat cisplatină în aceeaşi concentraţie după sinteză.

În cadrul celui de-**al doilea studiu**- *Potenţialul secretomului derivat din celule stromale mezenchimale umane în vederea dezvoltării de terapii pentru vindecarea rănilor cutanate*, s-a evaluat îmbunătățirea adusă unei matrici poroase de colagen bovin de tip I prin adiția unui agent trofic potent- secretomul derivat de la celule stromale mezenchimale (MSC) umane sub formă de mediu condiționat, în ceea ce privește colonizarea cu keratinocite și fibroblaste dermale umane, precum și efectul secretomului asupra proliferării, migrării celulare și angiogenezei *in vitro*.

Principalele rezultate originale (Fig. 2):

1. secretomul MSC a promovat colonizarea matricei de colagen cu keratinocite și fibroblaste, prin stimularea aderării și proliferării acestora;

2. secretomul MSC a modificat expresia genică a moleculelor implicate în sinteză și degradarea matricei extracelulare (colagen de tip I si III, αSMA, TIMP-1, TIMP-2, MMP-9);

3. secretomul MSC a prezentat proprietăți pro-angiogene, fiind motogen și chemo-atractant pentru celulele endoteliale.

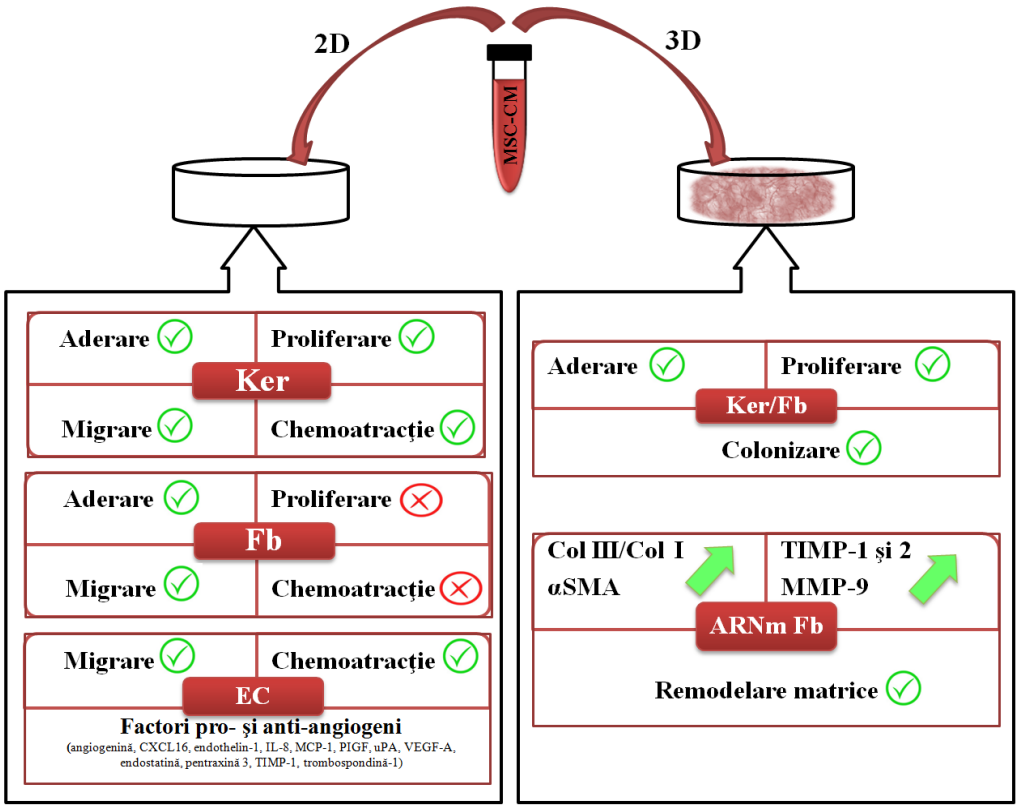

Figura 2. Reprezentare schematică sumarizând rezultatele prezentate cel de-al doilea studiu privind potențialului terapeutic al secretomului derivat de la celulele stromale mezenchimale izolate din măduvă osoasă combinat cu o matrice poroasă de colagen pentru tratamentul leziunilor cutanate.

Cel de-al treilea studiu inclus în teza de doctorat, se referă la selecția unor nanoparticule de argint (NP Ag), în vederea utilizării acestora ca agenți antibacterieni pentru încorporarea într-un compus pe bază de gel de fibrină pentru tratamentul rănilor cutanate. Alegerea NP Ag adecvate a fost fundamentată de o serie de experimente, care pe lângă efectul citotoxic asupra viabilității keratinocitelor, fibroblastelor dermale și celulelor endoteliale, a urmărit și migrarea celulară și dispunerea citoscheletului actinic, alături de acțiunea antibacteriană.

Principalele rezultate originale (Fig. 3) :

1. concentrația maximă de nanoparticule pentru care viabilitatea celulară a keratinocitelor nu a scăzut față de control a fost de 40 µg/ml pentru NP Ag EG și EG/PVP, 25 µg/ml pentru NP Ag PEG și respectiv, 30 µg/ml pentru NP Ag PEG PVP;

2. concentrația maximă de nanoparticule pentru care viabilitatea celulară a fibroblastelor și celulelor endoteliale nu a scăzut față de control a fost de 30 µg/ml pentru NP Ag EG și EG/PVP, 20 µg/ml pentru NP Ag PEG și respectiv, 25 µg/ml pentru NP Ag PEG PVP;

3. concentrația maximă de NP Ag care nu a afectat migrarea celulară a fost de 25 µg/ml pentru NP Ag EG și EG/PVP, și de 10 µg/ml în cazul NP Ag PEG si PEG/PVP, iar prezența NP Ag a indus o creștere a densității fibrelor de stres de actină.

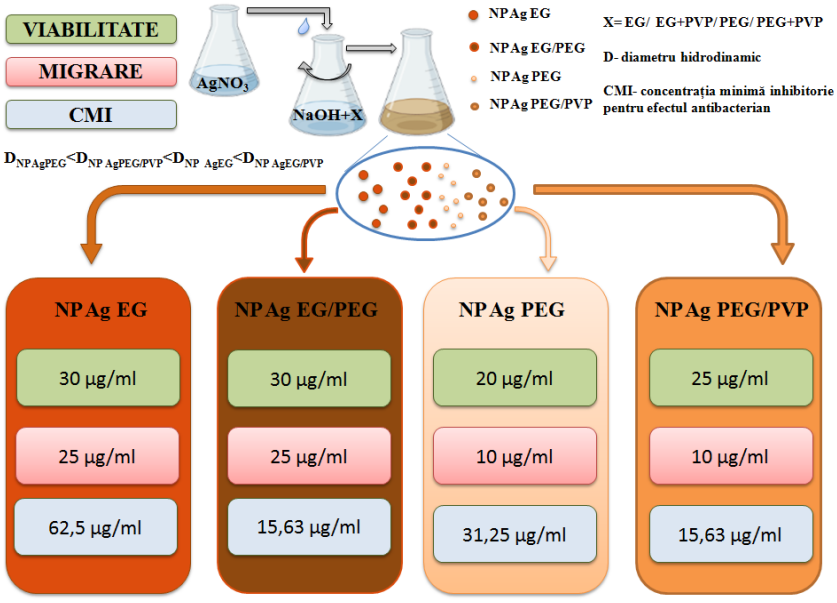

Figura 3. Reprezentare schematică a principalelor rezultate prezentate în cel de-al treilea studiu privind activitatea biologică a nanoparticulelor pe bază de argint sintetizate prin metoda

chimică, ce presupune reducerea alcalină a azotatului de argint, și funcționalizate cu etilen glicol (EG), polietilenglicol (PEG), cu sau fără polivinilpirolidonă (PVP). Dintre cele patru tipuri de nanoparticule studiate din punct de vedere al viabilitatii,capacitatii de a interfera cu migrarea celulară si a valorilor concentrației minime inhibitorii pentru acțiunea bacteriostatică, rezultatele au susținut utilizarea NP Ag EG/PVP până la concentrații de 25 µg/ml, fără a compromite viabilitatea și motilitatea keratinocitelor, fibroblastelor dermale și a celulelor endoteliale, fiind în același timp eficiente împotriva bacteriilor frecvent întâlnite în infecțile cutanate.

Cel de-al patrulea studiu din partea de contributii originale, s-a concentrat pe exosomii secretati de MSC, inițial alegându-se sursa cea mai adecvată: MSC izolate din țesut adipos (ADSC) sau măduva osoasă (BM-MSC). Exosomii astfel selectați au fost evaluați din punct de vedere al acțiunii stimulante asupra proliferării și migrării celulare, angiogenezei, a modificării expresiei genice și proteice în cadrul diferențierii fibroblastelor către miofibroblaste, și a capacității de a promova re-epitelizarea unei răni complete efectuate pe un model de cultură organotipica cutanata umană.

Modelul de cultura organotipica umana dezvoltat in cadrul programului de pregatire doctorala, reprezinta o alternativa la studiile pe animale, care, in cazul ranilor pielii, isi pierd din relevanta pentru translatia spre faza clinica, din cauza diferentelor majore anatomice si fiziologice fata de om [Parnell et al 2019]. De altfel, un model similar este deja utilizat pentru testele standard de iritație ale pielii conform ISO 10993-23:2021-Partea 23.

Principalele rezultate originale (Fig. 4):

1. exosomii izolați prin centrifugare diferențială din mediul condiționat secretat de MSC derivate din maduvă osoasă, au stimulat proliferarea și migrarea keratinocitelor și fibroblastelor umane;

2. exosomii în interacție cu fibroblastele dermale, chiar și în cazul unui mediu bogat în TGFβ1, nu au indus un fenotip pro-fibrotic, ci unul pro-vindecare, caracterizat de o creștere a expresiei proteice pentru colagen de tip I, fibronectină, decorină, precum și de o îmbunătățire a capacității contractile, însoțită de o mărire a expresiei enzimei lizil oxidaza, și nu a proteinei αSMA;

3. exosomii au conținut factori cu acțiune atât pro- cât și anti-angiogenă: Ang-2, ET-1, EG-VEGF/PK1, persefină, uPA și, respectiv, TSP-1, TIMP-1, PEDF, PAI-1, iar aceste nanovezicule au stimulat migrarea și formarea de tubi a celulelor endoteliale;

4. exosomii au susținut procesul de re-epitelizare pe un model de cultură organotipică cutanată umană lezat pe toată grosimea, similar cu mediu control pozitiv suplimentat cu factori de creștere.

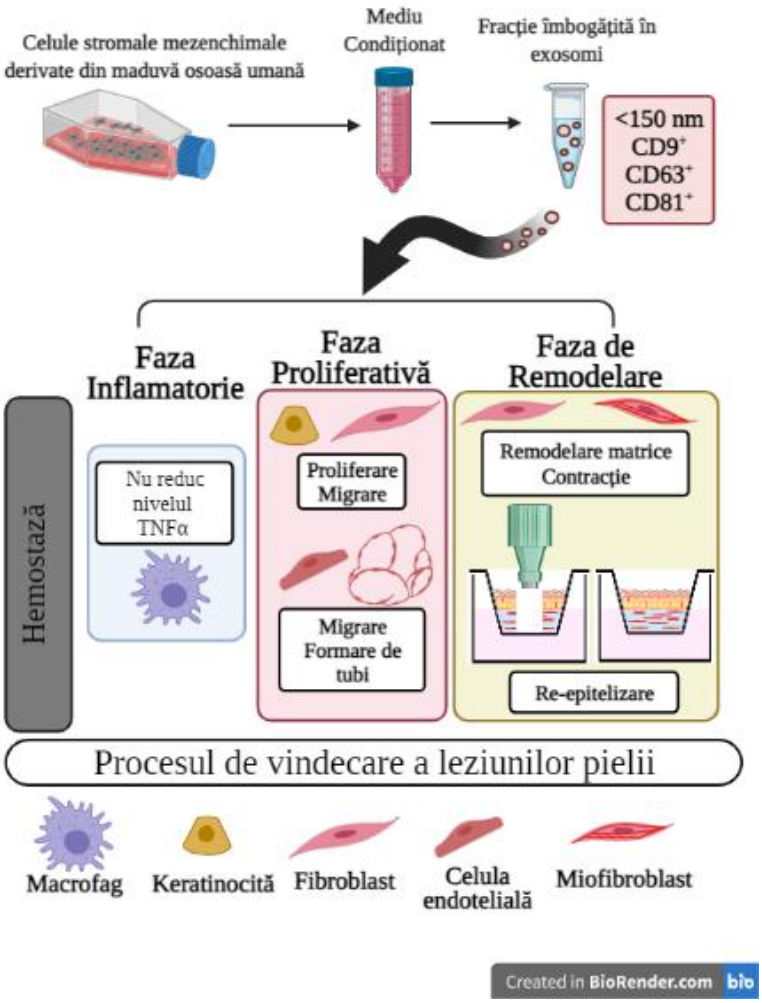

Figura 4. Reprezentare schematică sumarizând principalele rezultate din cel de-al patrulea studiu privind acțiunea exosomilor secretați de BM-MSC asupra principalelor tipuri celulare implicate în vindecarea rănilor cutanate [creat cu BioRender.com].

Astfel, în urma studiilor efectuate în cadrul programului de pregătire doctorală, s-au obținut următoarele rezultate originale:

1. Nanoparticulele superparamagnetice hibride pe bază de fier și poli(etilenimină), sintetizate prin metoda hidrotermală în condiții ce suportă în același timp încorporarea de principii active fără a compromite activitatea lor terapeutică, au fost biocompatibile atât pe celule normale cât și tumorale. Acest tip de nanoparticule au agregat spontan în mediu de cultură și permit astfel încorporarea de substanțe active în structurile micrometrice rezultate, pe care apoi le-au eliberat prin contact direct cu celulele. În cazul încorporării în timpul sintezei a unui compus anti-tumoral, precum cisplatina, la o concentrație fără efecte secundare, nanoparticulele au

prezentat un efect citotoxic asupra celulelor de glioblastom și o tendință de scădere a dimensiunii tumorii *in vivo*, susținând utilizarea lor ca vectori pentru eliberarea controlată.

2. Secretomul, sub formă de mediu condiționat, provenit de la celulele stromale mezenchimale (MSC) umane izolate din măduva osoasă, a avut efecte chemo-atractante și mitogene asupra keratinocitelor și celulelor endoteliale, cultivate în sistemul clasic bidimensional. Mai mult, acest secretom a promovat colonizarea matricelor tridimensionale poroase de colagen bovin de tip I cu keratinocite și fibroblaste dermale; de asemenea, prezența mediului condiționat a modulat expresia genică a moleculelor implicate în sinteză și degradarea matricei extracelulare (colagen de tip I și III, αSMA, TIMP1, TIMP2, MMP14). Astfel, datele obținute au susținut fezabilitatea combinării matricei de colagen cu secretomul derivat de la MSC în vederea utilizării sub forma unui produs acelular disponibil „direct de pe raft" pentru vindecarea rănilor cutanate.

3. Nanoparticulele de argint (NP Ag) funcționalizate cu etilen glicol, etilen glicol și poli(vinilpirolidonă), poli(etilenglicol), sau poli(etilenglicol) și poli(vinilpirolidonă) sintetizate prin metoda reducerii nitratului de argint, au prezentat nivele de citotoxicitate diferite pentru keratinocite, fibroblaste dermale și celule endoteliale; cea mai mare concentrație care nu a afectat viabiliatatea și capacitatea migratorie fiind înregistrată pentru NP Ag cu etilen glicol și poli(vinilpirolidonă)- 25 µg/ml, care, corelată cu concentrația minimă inhibitorie pentru efectul antibacterian- 15,63 µg/ml, a susținut utilizarea acestor nanoparticule pentru potențiale aplicații în cazul tratamentului leziunilor pielii.

4. Exosomii secretați de MSC izolate din măduva osoasă umană au avut un efect stimulator mai puternic asupra migrării keratinocitelor, comparativ cu cei secretati de MSC izolate din țesut adipos; acești exosomi selectați au promovat proliferarea keratinocitelor și fibroblastelor dermale, inducând un fenotip pro-vindecare la nivelul fibroblastelor diferențiate către miofibroblaste, caracterizat de o creștere a contractilitatii fără modificarea expresiei de αSMA. De asemenea, aceste nanovezicule au susținut migrarea celulelor endoteliale și formarea de tubi, sugerând o acțiune pro-angiogenă, datorată cel mai probabil citokinelor și factorilor de creștere identificați la nivelul acestora. Mai mult, tratarea cu exosomi a leziunilor efectuate pe culturilor organotipice cutanate umane, care mimează structura pielii, a fost asociată cu o re-epitelizare completă, sprijinind astfel aplicarea acestui tip de vezicule extracelulare pentru terapia rănilor tegumentului.

INTRODUCTION AND OBJECTIVES

Cardiovascular diseases remain the leading cause of mortality worldwide, with over 17.9 million deaths annually (32% of total deaths), especially in underdeveloped countries[1]. Statistics from Romania show that 3.5 million Romanians suffer from some form of cardiovascular disease, with a mortality rate of 57% of total deaths (approximately 4 out of 10 deaths among men and 6 out of 10 deaths among women[2]). The term refers to all conditions/diseases that affect the heart and blood vessels, with a significant portion being attributed to atherosclerosis.

The vascular endothelium is the inner layer that lines the blood vessel, representing a selective barrier with a number of key functions in ensuring adequate hemostatic stability and vascular tone by maintaining the balance between vasodilation and vasoconstriction. The functional integrity of the endothelium is an essential element for the health of the cardiovascular system, and mechanical/chemical injury or exposure to risk factors leads to endothelial dysfunction, which plays a major role in the onset and progression of cardiovascular diseases, particularly atherosclerosis and hypertension (Pearson, 2000).

Atherosclerosis is a chronic inflammatory fibroproliferative disease, with an autoimmune component, affecting large and medium-sized arteries. It is a progressive, multistage, multifactorial, and polygenic vascular disease involving successive events: in the initial stage, endothelial cells are damaged, leading to endothelial dysfunction, followed by endothelial activation, the formation of lipid streaks, the development of the fibrous cap, and, in advanced stages, plaque rupture and thrombosis. Risk factors underlying the atherogenic process, especially dyslipidemia and hypertension, together with sustained inflammation and increased oxidative stress, lead to endothelial dysfunction, which contributes to plaque formation and the progression of atherosclerosis, ultimately resulting in cardiovascular diseases (Lusis, 2000; Singh et al., 2002; Manduteanu and Simionescu, 2012).

In the pathogenesis of atherosclerosis, perivascular adipose tissue (PVAT), located around the atherosclerotic lesion, plays a very important role. It secretes pro-inflammatory cytokines known as adipocytokines. These cytokines have access to the adjacent vascular wall

[1]https://ec.europa.eu/eurostat/

[2] https://insp.gov.ro/2023/12/04/decembrie-2023-campania-inimi-in-dar/

structure via diffusion through the vasa vasorum and are involved in regulating vascular tone (Tanaka and Sata, 2018).

Vascular calcification (a clinical marker associated with atherosclerosis) is defined as the deposition of minerals in the form of calcium phosphate deposits in the vascular wall. It is a complication of the atherosclerotic process in the advanced stages of the disease (Shi et al., 2020). Calcification represents a systemic disease that leads to plaque instability due to the ability of smooth muscle cells (SMCs) to adopt multiple secretory phenotypes (osteogenic, chondrogenic, osteoclastic, adipogenic) under the influence of an active process resembling bone formation and calcification factors/proteins (Durham et al., 2018; Mackey et al., 2007).

Cardiopulmonary disease encompasses a wide range of serious conditions that affect both the structure and function of the heart (cardiac) and the lungs (pulmonary). These two organs are closely linked, so any problem affecting one organ may compromise the integrity of the other. The most common cardiopulmonary diseases include pulmonary arterial hypertension, atherosclerosis, and coronary artery disease.

In 2021, it was estimated that there were 192,000 prevalent cases of pulmonary arterial hypertension globally. Of these, 119,000 cases were recorded in women (62%) and 73,100 cases in men (38%). The age-adjusted prevalence was 2.28 cases per 100,000 population. The prevalence increased with age, with the highest rates among people aged 75-79 years. In 2021, 22,000 deaths were attributed to pulmonary arterial hypertension worldwide, with an age-adjusted mortality rate of 0.27 deaths per 100,000 population[3].

Pulmonary arterial hypertension is a multifactorial disease characterized by progressive remodeling of the pulmonary artery, which involves complete obliteration of the vessel, leading to increased vascular resistance and ultimately resulting in right ventricular hypertrophy and even heart failure, with an average arterial pressure greater than 25 mmHg at rest[4]. Both pulmonary hypertension and the vascular calcification process associated with atherosclerosis lead to the development of perivascular fibrosis and vascular wall stiffening. Both are associated with structural, functional, and mechanical changes in the vascular wall, characterized by a series of events: increased arterial stiffness, reduced elasticity, impaired

[3] GBD 2021 Pulmonary Arterial Hypertension Collaborators. **Global, regional, and national burden of pulmonary arterial hypertension, 1990–2021: a systematic analysis for the Global Burden of Disease Study 2021.** *The Lancet Respiratory Medicine.* 18 October 2024. doi: 10.1016/ S2213-2600(24)00295-9.

[4] https://www.nhlbi.nih.gov/health/pulmonary-hypertension

distensibility, established endothelial dysfunction, and increased vascular tone (Hu et al., 2020).

Fibrosis is a dynamic process, present in both large and small arteries, which in the early stages represents a reversible adaptive response involved in vascular repair. However, the fibrogenic process is progressive, leading to the worsening of vascular wall stiffness with gradual expansion into the interstitial space. In large vessels, fibrosis causes changes in blood flow hemodynamics, with subsequent damage to peripheral tissues (Harvey et al., 2016).

Arterial stiffening is primarily caused by excessive fibrosis and reduced elasticity, in association with increased synthesis of collagen deposits, pronounced degradation and fragmentation of elastin fibers, necrosis in the media layer, calcification, and cross-linking of collagen molecules through final glycation processes (Jia et al., 2015). Vascular fibrosis, together with arterial stiffening, are events that result from the onset of pulmonary/arterial hypertension and a combination of pro-hypertensive factors acting on the extracellular matrix composed of collagen, elastin, fibronectin, and proteoglycans. These pro-hypertensive factors include pro-inflammatory cytokines and interleukins, activation of the renin-angiotensin-aldosterone system, oxidative stress, vasoactive substances (such as Ang II – angiotensin II, ET-1 – endothelin 1), reduced bioavailability of NO (nitric oxide), which in turn stimulate intracellular profibrotic signaling cascades. Following these events, MMP-2 and MMP-9 (Matrix Metalloproteinases 2 and 9) are activated, TIMP (Tissue Inhibitor of Metalloproteinases) activity decreases, the expression of PAI-1 (Plasminogen Activator Inhibitor) increases, which is associated with the pathogenesis of pulmonary fibrosis. Other molecules involved include CTGF (Connective Tissue Growth Factor) – playing a role in cellular adhesion; Galectin-3 – exhibiting a profibrotic role in various organs such as the liver, kidneys, lungs, and myocardium, also playing a key role in cell proliferation, adhesion, differentiation, angiogenesis, and apoptosis (Mozos et al., 2017; Harvey et al., 2016; Palombo and Kozakova, 2016).

Although they affect different parts of the cardiovascular system, atherosclerosis and pulmonary arterial hypertension are two pathologies that share numerous pathological aspects, such as endothelial dysfunction, chronic inflammation, vascular remodeling, smooth muscle cell (SMC) proliferation, immune dysfunction, and cardiovascular complications, involving similar mechanisms in the disease progression. Conventional treatments, such as

antihypertensive drugs and statins, control only some of the risk factors but do not always prevent the complete progression of the diseases or reduce the changes already produced. Additionally, many patients do not respond sufficiently well to standard treatments, and adverse effects limit treatment options. Genetic and molecular variability among patients underscores the need for developing personalized therapeutic strategies that can address the specificities of each patient.

Extracellular vesicles (EVs) released by endothelial cells under pathological conditions, such as in atherosclerosis, are biomarkers of endothelial dysfunction and can aggravate disease progression by transferring inflammatory signals between cells. The term "extracellular vesicles" (EVs) refers to a distinct class of small particles in the nanometer range (exosomes (40-100 nm)) and microparticles or microvesicles (MVs (100-1500 nm)), which are released by cells physiologically, with this release being amplified under pathological conditions. These vesicles are rich in lipids, proteins, and microRNA (miRNA), which have the ability to post-transcriptionally regulate gene expression in target cells (Ozkocak et al., 2022). Therapies based on small interfering RNA (siRNA), miRNA, and EVs may allow for precise targeting of underlying pathological mechanisms, such as inflammation, endothelial dysfunction, or vascular remodeling, by gene silencing of key molecules. These new therapies are crucial for reducing the mortality and morbidity associated with cardiovascular and cardiopulmonary diseases (Zhang et al., 2017).

Smad2 and Smad3 molecules are essential effectors in the TGF-β1 signaling pathway, which regulates the development and progression of atherosclerosis by influencing processes such as fibrosis, extracellular matrix (ECM) remodeling, and the phenotypic change of vascular smooth muscle cells. Targeted therapy based on siRNA to block Smad2/3 function could protect against these pathogenic effects and, therefore, might be a promising approach for the prevention and treatment of atherosclerosis. Activator protein 1 (AP-1) is a crucial transcription factor that regulates key cellular processes, such as proliferation, differentiation, and apoptosis, responding to extracellular stimuli and stress signals. The use of targeted siRNA to block the AP-1 transcription complex could provide an innovative approach to restore structural and functional changes in pulmonary arterial hypertension (PAH) induced by atherosclerosis and reduce the associated fibrotic and inflammatory processes.

Structure of the Doctoral Thesis

This doctoral thesis is organized into two main parts, divided into six chapters and two original studies.

In the first part of the thesis – ***State of the Art*** – the theoretical aspects are discussed in detail across six chapters. **Chapter 1** and **Chapter 2** describe in detail the anatomy and physiology of the cardiovascular system, the stages of atherogenesis, the molecular mechanisms, and the genetic factors underlying atherosclerotic cardiovascular disease. **Chapter 3** describes the anatomy and physiology of the respiratory system, with a focus on the intrapulmonary airways, while **Chapter 4** details concepts related to pulmonary arterial hypertension (classification, molecular mechanisms, treatment, and the role of miRNAs in the disease pathology). **Chapter 5** presents extracellular vesicles (exosomes and microvesicles) along with their therapeutic applications in numerous pathologies. **Chapter 6** discusses concepts related to gene technologies based on siRNA in cardiovascular diseases.

The second part of the thesis – ***Original Contributions*** – presents the original results obtained in two studies. Both studies focus on endothelial dysfunction as a key phenomenon in the two pathologies studied. Currently, fundamental research is focused on the development of innovative therapies that allow for early diagnosis and personalized treatment of cardiovascular and cardiopulmonary diseases, to intervene before irreversible damage occurs. New approaches, such as the use of biomarkers and nanotechnology, can help identify and address molecular and cellular dysfunctions early. Both studies presented in this doctoral thesis aimed to use therapeutic strategies based on extracellular vesicles and siRNA to regress vascular endothelial dysfunction in the context of two pathologies: atherosclerotic cardiovascular disease and cardiopulmonary disease (pulmonary arterial hypertension). The two diseases were investigated in vivo through two murine experimental models that aimed to reproduce as faithfully as possible the manifestations encountered in patients: the simultaneous hyperlipidemic-hypertensive hamster model and the MCT-induced pulmonary arterial hypertension hamster model.

STUDY (I) Vascular Wall Damage in Atherosclerotic Cardiovascular Disease; The Beneficial Effect of Extracellular Vesicle-Based Therapy on Endothelial Dysfunction and Involved Molecular Markers

The purpose of this study was to investigate the effects of nanotherapy based on extracellular vesicles (EVs) derived from adipose tissue-derived mesenchymal stem cells (ADSCs) or bone marrow mesenchymal stem cells (BM-MSCs), either transfected or not with Smad2/3siRNA, on endothelial dysfunction and key molecules involved in atherosclerosis. To this end, an animal model of atherosclerosis, the hyperlipidemic-hypertensive Golden Syrian hamster, was transplanted with EVs (ADSCs) or EVs (BM-MSCs), transfected or not with Smad2/3siRNA, or with Smad2/3siRNA alone. Thus, the effects of EVs (ADSCs) or EVs (BM-MSCs) transfected or not with Smad2/3siRNA on the consequences of an atherogenic diet on vascular health were compared. In general, EVs or siRNA technology are widely used in the development of experimental therapies for many pathologies.

The general objective of this study was to characterize the structural and functional aspects of the 'in vivo' experimental model of atherosclerotic cardiovascular disease and to validate EVs (ADSCs) or EVs (BM-MSCs) as potential therapeutic strategies in restoring vascular function.

The following **specific objectives** were set:

(1) Generation of the animal model of atherosclerotic cardiovascular disease transplanted or not with EVs (ADSCs) or EVs (BM-MSCs) from healthy hamsters, transfected or not with Smad2/3siRNA;

(2) Investigation of endothelial dysfunction, vascular calcification, and specific inflammatory markers in the experimental model of atherosclerotic cardiovascular disease;

(3) Exploration of mechanisms involved in vascular dysfunction by investigating the Ang II; TGF-β1/Smad2,3 signaling pathway, which activates transcription factors such as ATF2, NF-kB, AP-1, leading to the subsequent alteration in the expression of miRNA-21, miRNA-192, miRNA-200b, miRNA-29a, miRNA-210, and miRNA-146a;

(4) Evaluation of the potential beneficial effect of EVs 'in vivo'.

Results Obtained in Study I

The results of Study I demonstrate that: Compared to the HH group, treatment with EVs (ADSCs) or EVs (BM-MSCs), alone or combined with Smad2/3siRNA, or treatment with Smad2/3siRNA alone, significantly reduces plasma lipid levels and improves the structure and function of affected blood vessels (aortic artery and carotid artery) by decreasing the expression of molecular and cellular targets involved in the progression of atherosclerotic disease, such as:

- Decreased expression of structural and inflammatory markers, including COL1A1, α-SMA, Cx43, VCAM-1, MMP-2.
- A slight infiltration of total macrophages/M1 and T-cells.
- Reduced ROS production in the cytosol.
- Significant reduction in plasma concentrations of TGF-β1 and Ang II proteins.
- Significant structural and functional improvements: thinning of the arterial wall, increased inner diameter, improved distensibility, reduced Vel and VTI, and increased contractile and relaxation responses to NA and ACh.
- A reduced protein expression profile of Smad2/3, ATF-2, NF-kBp50/p65.
- Significant reduction in the expression levels of miRNA-21, miRNA-29a, miRNA-192, miRNA-200b, miRNA-210, and miRNA-146a.

Conclusions of Study I:

- EV-based therapies derived from stem cells, particularly EVs (ADSCs), led to regression of structural and functional changes in the vascular wall and the expression of key orchestrators involved in endothelial dysfunction induced by atherosclerosis.
- Smad2/3 siRNA transfection of EVs enhanced the ability of EVs (ADSCs) or EVs (BM-MSCs) to regress the atherosclerotic process mediated by inflammation.

The results of this study were published in the journal *Frontiers in Cell and Developmental Biology*, 2022, 10:817180, DOI: 10.3389/fcell.2022.817180, with an impact factor of 6.68, Q1 (Comarița et al., 2022).

STUDY (II) Effects of siRNA AP-1 Mediated Therapy on Pulmonary Arterial and Right Ventricular Dysfunction Associated with Cardiac and Pulmonary Fibrosis in Cardiopulmonary Diseases

The purpose of this study was to explore vascular dysfunction and associated perivascular fibrosis in an experimental animal model of pulmonary arterial hypertension; investigating the potential beneficial effect of AP-1 siRNA.

For generating the experimental animal model with pulmonary hypertension, monocrotaline (MCT), a toxic pyrrolizidine alkaloid, is used, which induces pulmonary arterial hypertension within 1-2 weeks after administration. For the desired effect, MCT must undergo conversion into its active form (MCTP) in the liver via oxidative processes mediated by cytochrome P450 (Nogueira-Ferreira et al., 2015; Stenmark et al., 2009). After MCTP becomes metabolically active, it exerts pneumotoxic effects that cause endothelial cell damage in the pulmonary artery, contributing to endothelial dysfunction. Other pathophysiological and histopathological features of MCT administration include vascular remodeling, right ventricular hypertrophy, acute vascular inflammation (infiltration of monocytes/macrophages, T lymphocytes, dendritic cells), hyperplasia and thickening of the vascular wall, particularly in the intima and media, the installation of fibrosis, muscularization of initially non-muscularized arteries and arterioles through increased α-SMA expression, formation of plexiform lesions (a hallmark of advanced stages) leading to lumen obstruction, thickening of the adventitia, and vessel stiffening (Bueno-Beti et al., 2018). Recent studies have shown that in animal models of pulmonary hypertension, reduced expression of miRNAs regulating anti-apoptotic molecules like Bcl-2 and Bcl-X, von Willebrand factor (vWF), and VEGFR2 receptor, is associated with the presence of proliferative perivascular lesions in the outer tunica (Ruiter et al., 2013).

The general objective of this study was to obtain and characterize the experimental 'in vivo' model with cardiopulmonary disease and to follow the effect of AP-1 siRNA as a potential therapeutic strategy in the recovery of vascular dysfunction and associated perivascular fibrosis.

The following **specific objectives** were set:

(1) Generation of the animal model with cardiopulmonary disease (pulmonary hypertension and associated perivascular fibrosis);
(2) Evaluation of endothelial dysfunction, perivascular fibrosis, and specific inflammatory markers in the experimental cardiopulmonary disease model;
(3) Evaluation of pulmonary fibrosis and specific inflammatory markers in the experimental cardiopulmonary disease model;
(4) Exploration of mechanisms involved in vascular dysfunction and perivascular fibrosis by investigating the PKC - FAK/ILK – TAK- JNK/ERK signaling pathway;
(5) Investigation of the potential beneficial effect of siRNA AP-1 'in vivo'.

Results Obtained in Study II

The results of Study II demonstrate that: Compared to the MCT group, treatment with siRNA AP-1 had significant beneficial effects on the investigated tissues (pulmonary artery, right ventricle, and lungs) contributing to:

- Reduction of plasma concentrations of TGF-β1/ET-1/IL-1β/TNF-α.
- Reduced cytosolic ROS production in the pulmonary artery, right ventricle, and lungs, along with significant improvements in the ultrastructure of these tissues.
- Decreased expression of inflammatory and fibrotic markers in the pulmonary artery (COL1A, Fibronectin, Vimentin, α-SMA, CTGF, Calponin, MMP-9), right ventricle, and lungs (COL1A, CTGF, Fibronectin, α-SMA, F-actin, OB-cadherin), and an increase in endothelial markers (CD31, VE-cadherin) in the pulmonary artery.
- Structural and functional improvements in the pulmonary artery (reduced Vel, restored vascular reactivity (NA contraction and ACh relaxation)) and right ventricle (increased internal cavity diameter in diastole, increased TAPSE, and PRVOF), associated with a reduction in systolic and diastolic blood pressure and heart rate.
- Reduced expression profile of AP-1S3/pFAK/FAK/pERK/ERK proteins.
- Significant reduction in the expression levels of miRNA-145, miRNA-210, miRNA-21, and miRNA-214, along with an increase in miRNA-124 and miRNA-204 in the pulmonary artery.

- Significant increase in the expression levels of miRNA-145 and miRNA-204, along with a decrease in miRNA-210, miRNA-21, and miRNA-214 in the right ventricle.

Conclusions of Study II:

- siRNA AP-1-based therapy improved pulmonary arterial and right ventricular function, associated with the regression of perivascular and interstitial fibrosis in the pulmonary artery, right ventricle, and lungs, and a reduction in key inflammatory and fibrotic markers in hamsters with cardiopulmonary disease (pulmonary arterial hypertension).

The results of this study were published in the *Journal of Translational Medicine*, 2024, DOI: 10.1186/s12967-024-04933-1, with an impact factor of 8.44, Q1 (Comarița et al., 2022).

DISSEMINATION AND EXPLOITATION OF RESULTS

The results obtained during the doctoral program (2020-2025) within the Institute of Cellular Biology and Pathology "Nicolae Simionescu" of the Romanian Academy were employed as follows:

- Publications in ISI-indexed journals (5): 2 as first author and 3 as co-author
- Abstracts published in ISI-indexed journals (6): 4 as main author and 2 as co-author
- Participation in international conferences (12) in the form of 1 oral presentation and 11 posters
- Awards granted by UEFISCDI (3) and 1 award granted by the Romanian Society for Cell Biology (RSCB)
- Data included in a patent application at OSIM
- Doctoral scholarship: Romanian Academy (SCOSAAR)
- H-index: 5
- Citations: 108 (Google Scholar profile) [5]

INTRODUCERE ŞI OBIECTIVE

Ateroscleroza este una dintre principalele cauze de mortalitate în ţările dezvoltate. Datele din literatură susţin că ateroscleroza este o boală multifactorială in care inflamația și dislipidemia se intersectează și că indiferent de inițiator, ambele participă din stadiile incipiente până la soarta finală a plăcii ateromatoase. Unul dintre factorii de risc majori în ateroscleroză este modificarea homeostaziei plasmatice, cum ar fi hipercolesterolemia. Aceasta afectează inițial celulele endoteliale, pe care le activează şi ca urmare, acestea incep să exprime noi molecule de adeziune și factori chemotactici ce conduc la initierea unui proces inflamator. Inflamația implică recrutarea de celule imune circulante care agravează și accelerează dezvoltarea ateromului [1]. Răspunsul inflamator inițial poate fi considerat ca un mecanism de apărare, dar amplificarea sa ulterioară accelerează ateroscleroza [2, 3]. De asemenea, componentele lipoproteinelor plasmatice, diverse structuri microbiene sau proteinele de șoc termic induc un proces inflamator care, de la sine, poate genera formarea plăcii aterosclerotice. Aproximativ jumatate dintre pacienți dezvoltă ateroscleroză în absența hipercolesterolemiei sistemice [4].

Deși întregul sistem vascular este expus factorilor de risc, ateroscleroza se dezvoltă preferențial in anumite zone precum punctele de ramificație, peretele exterior al bifurcațiilor, peretele interior al curburilor sau valvele cardiace, zone caracterizate prin variații ale stresului de curgere sau tulburări ale fluxului [5, 6]. Dezvoltarea ateromului este un proces continuu. Implicarea progresivă a celulelor rezidente și nerezidente vasculare și a produselor lor de secreție defineste o secvență de etape consecutive care duc de la formarea de striuri lipidice, la placa fibro-lipidică și în cele din urmă, la ruptura plăcii și aterotromboză [2].

Lipoproteinele sunt structuri alcătuite în principal din lipide şi proteine. Ele îndeplinesc funcţia de transport a colesterolului, trigliceridelor şi fosfolipidelor în plasmă. Lipoproteinele prezintă două componente: un înveliş extern hidrofil care conţine apolipoproteine, fosfolipide şi colesterol neesterificat şi nucleul central hidrofob, alcătuit din colesterol esterificat şi trigliceride. Apolipoproteinele asigură solubilitatea lipoproteinelor, dar sunt şi cofactori enzimatici sau liganzi pentru receptori celulari specifici. Se cunosc patru clase majore de apolipoproteine: A, B, C şi E. Apolipoproteina E (apoE) este o componentă a lipoproteinelor plasmatice, care participă la îndepărtarea lipoproteinelor aterogene din circulaţie. Studiile *in vitro* şi *in vivo* au arătat că mutaţii ale apoE sunt asociate cu nivel crescut de colesterol şi ateroscleroză prematură, atât în animale experimentale, cât şi la oameni [7]. Nivelul fiziologic de apoE în plasmă este asociat cu scăderea riscului bolilor cardiovasculare, prin reducerea nivelului de lipoproteine aterogene circulante, prin efluxul de colesterol, dar şi prin inhibarea expresiei moleculelor de adeziune la suprafaţa endotelială [8].

Progresele recente în terapiile cardiovasculare au dus la dezvoltarea de noi agenți care vizează apolipoproteine specifice pentru a reduce riscul de ateroscleroză [9, 10].

Știința nanoparticulelor schimbă rapid perspectiva diferitelor domenii științifice și definește noi platforme tehnologice. Acest lucru este și mai evident în domeniul nanomedicinei în care au fost utilizate nanoparticulele ca instrument pentru tratamentul și diagnosticul multor boli [11]. Cu toate acestea, în ciuda imensului beneficiu conferit, există și restricţionari ale acestei tehnologii care vizează efectele pe termen scurt și lung asupra organismului uman.

Scopul acestei teze de doctorat a fost determinarea unor mecanisme de reglare genică ce duc la diminuarea expresiei unor apolipoproteine și producerea de nanoparticule pe bază de fulerenol cuplate cu apoE (Full-apoE) care mimeaza particulele de lipoprotein, care ar putea fi utilizate pentru a compensa expresia scazuta a apoE.

Ipoteza noastră afirmă că nanoparticulele pe bază de fulerenol, având legate pe suprafaţă molecule de apoE (Full-apoE), imită lipoproteinele bogate în apoE, oferind beneficii anti-aterosclerotice semnificative, fără efecte secundare.

STRUCTURA TEZEI DE DOCTORAT

În prima parte a tezei sunt prezentate datele din literatură care vizează funcțiile specializate ale lipoproteinelor şi apolipoproteinelor asociate, împreună cu rolurile acestora în circulaţia lipidelor în plasmă și în dezvoltarea aterosclerozei (**Capitolul 1**), precum şi exemple de noi terapii promițătoare care vizează apolipoproteine specifice și care ar putea reduce în cele din urmă riscul de ateroscleroză.

În **Capitolul 2** sunt sintetizate nanotehnologiile personalizate pentru ţintirea celulelor implicate în dezvoltarea placilor aterosclerotice şi principalele clase de nanoparticule utilizate în diagnosticul sau tratamentul aterosclerozei. De asemenea, au fost evidentiate metodele de sinteză, stabilitatea și principalele caracteristici antioxidante ale moleculei de fulerenol.

În partea a doua a tezei sunt prezentate rezultatele originale obţinute asupra reglarii genice a unor apolipoproteine importante în procesul de aterogeneză şi sinteza unor nanoparticule cu potenţial anti-aterosclerotic. În **capitolul 3** sunt prezentate rezultatele obţinute *in vivo* şi *in vitro* asupra reglarii unor apolipoproteine implicate în dezvoltarea placilor aterosclerotice de către unele polihidrocarburi aromatice prezente în mediu: Bisfenol A (BPA) şi Benzo(a)piren (BaP). Atât BPA cât şi BaP activează factori de transcriere care se leagă la situsurile specifice de la nivelul promotorilor apolipoproteinelor apoA-I şi/sau apoC-I şi contribuie la dezvoltarea leziunilor aterosclerotice, prin mecanisme care implică activarea NF-κB sau AHR.

Metodele folosite şi prezentate în **capitolul 4** au avut ca scop obţinerea prin biotehnologie a proteinei apoE-ε3 marcată şi secretată de celule mamaliene, pentru a construi nanosisteme cu izoforma apoE-ε3.

În **capitol 5** sunt prezentate metodele pentru obţinerea de nanoparticule pe bază de fulerenol, complexate cu apoE şi testarea efectului anti-aterosclerotic *in vivo* pe linia de şoareci apoE deficienţi. Nanoparticulele obţinute pe bază de fulerenol şi apoE combină proprietățile anti-hiperlipidemice și anti-oxidative ale fulerenolului cu proprietățile anti-aterosclerotice și anti-inflamatorii ale apoE și pot reprezenta o strategie promițătoare pentru combaterea aterosclerozei.

CONCLUZII GENERALE

Deși rezultatele clinice în bolile coronariene s-au îmbunătățit considerabil în ultimele câteva decenii, incidența infarctului miocardic și a accidentului vascular cerebral continuă să rămână ridicată. Nanotehnologia oferă o abordare unică prin dezvoltarea nanoparticulelor multifuncționale, specifice celulei. Aceasta va conduce spre noi frontiere în diagnosticare și terapie prin țintirea moleculelor implicate în procesele care conduc la ateroscleroză, păstrând astfel potențialul de îmbunătățire continuă a rezultatelor cardiovasculare.

În această lucrare, am analizat reglarea a unor apolipoproteine importante în procesul de aterogeneză de către substanţele prezente în mediu: bisfenol A (BPA) şi benzo[a]piren (BaP). Pornind de la ipoteza că efectele pro-aterogenice ale BPA sunt mediate, cel puțin parțial, de reglarea negativă a genei APOA-I, conducând astfel la o cantitate scăzută de HDL anti-aterosclerotic, am investigat dacă BPA modulează expresia genei APOA-I și mecanismele moleculare implicate în această reglare. Rezultatele obţinute pe șoarecii $LDLR^{-/-}$ tratați cu BPA au arătat că (i) BPA a crescut aria leziunilor aterosclerotice în aortele șoarecilor $LDLR^{-/-}$; (ii) a scăzut nivelurile HDL și apoA-I și a crescut concentrațiile plasmatice de colesterol și trigliceride; (iii) mecanismul acestui proces implică activarea căilor NF-kB și în consecință, reducerea expresiei apoA-I în ficat. Datele noastre au demonstrat că promotorul APOA-I conține situsuri funcționale de legare a NF-kB care sunt responsabile pentru reglarea expresiei genice APOA-I indusă de BPA.

De asemenea, am investigat potențialul modulator al BaP asupra expresiei unor apolipoproteine cheie în metabolismul lipidic: apoA-I, apoC-I şi apoE, și am urmarit un posibil mecanism prin care BaP modulează expresia acestor apolipoproteine, prin studii *in vitro,* în hepatocite. Rezultatele acestui studiu arată că BaP induce reglarea apoA-I şi apoC-I în hepatocite printr-un mecanism dependent de Aryl hidrocarbon receptor (AHR). AHR se leagă la situsurile active din promotorii apoA-I şi apoC-I şi conduce la scăderea expresiei apoA-I, respectiv creşterea expresiei apoC-I, în hepatocite, ceea ce determină un potenţial risc pentru dezvoltarea şi mentinerea placilor aterosclerotice. Un posibil mecanism de reglare a acestor apolipoproteine pe baza rezultatelor obţinute şi a ceea ce se cunoaşte din literatura ar putea fi atât direct prin AHR, cât şi indirect prin dimerizarea altor factori de transcriere.

În finalul lucrării am abordat strategii nanotehnologice care ţintesc regresia placilor aterosclerotice. Pentru aceasta am aprofundat tehnicile de inginerie genetică pentru obţinerea de

plasmide care să exprime apoE recombinantă. Cu aceste plasmide, am transfectat stabil celule mamaliene care au sintetizat si secretat apoE în mediul de cultură, de unde am putut izola proteina de interes, prin cromatografie de afinitate. Am utilizat această proteină în scopul obţinerii unor nanoparticule cu potenţial terapeutic în ateroscleroză.

Nanoparticulele cu apoE, au fost utilizate pentru tratarea şoarecilor apoE deficienţi şi am observat câteva beneficii anti-aterosclerotice semnificative. Rezultatele obţinute în urma administrării nanoparticulelor Full-apoE (NP Full-apoE) derivatizate la șoarecii apoE$^{-/-}$ aterosclerotici au arătat că NP Full-apoE: (i) au fost incluse în fracțiile HDL și VLDL; (ii) au fost distribuite în principal în ficat, dar și în alte țesuturi (cum ar fi creier, plămân și rinichi); (iii) au determinat o expresie hepatică crescută a moleculelor importante implicate în metabolismul lipidic (cum ar fi apoA-I, ABCA1, SR-B1 și sortilina); (iv) au determinat o scădere a nivelului de colesterol plasmatic și (v) au inhibat evoluția plăcilor aterosclerotice. Nanoparticulele pe bază de fulerenol care poartă complexat cu apoE-ε3 combină proprietățile anti-hiperlipidemice și anti-oxidative ale fulerenolului cu proprietățile anti-aterosclerotice și antiinflamatorii ale apoE-ε3 și pot reprezenta o strategie promițătoare pentru ateroscleroză.

Principalele **contribuţii originale ale acestei lucrări sunt:**

(i) mecanismul de reglare genică pentru APOA-I ca raspuns la activitatea BPA, prin activarea NF-kB şi identificarea situsurilor responsabile de legare a factorilor de transcriere de pe promotorul genei APOA1, avand în consecinţă scaderea expresiei genice APOA-I.

(ii) reglarea genică a APOA-I şi APOC-I ca răspuns la BaP prin activarea AHR şi translocarea în nucleu, unde se leagă la promotorii acestor gene inducând o scadere a APOA-I şi o creştere a APOC-I, ceea ce indică un mecanism pro-aterosclerotic.

(iii) obţinerea de vectori plasmidiali care să codifice apoE recombinantă şi transfecţia stabilă a celulelor endoteliale (bEnd.3) şi macrofage (RAW 293.7) care să exprime proteina apoE glicozilată în mediul de creştere al celulelor.

(iv) Conceperea și caracterizarea nanoparticulelor pe bază de fulerene cuplate cu apoE şi validarea *in vivo* a efectelor anti-aterosclerotice ale Full-apoE.

VALORIFICAREA REZULTATELOR

Rezultatele obținute în perioada desfasurarii programului doctoral din cadrul Institutului de Biologie și Patologie Celulară „Nicolae Simionescu" al Academiei Române au fost:

● publicate în 4 lucrări în reviste indexate ISI: 1 ca prim-autor, 1 în calitate de co-autor şi 2 recenzii;

● prezentate în cadrul conferințelor naţionale şi internaționale sub forma a 2 prezentări orale și 6 postere.

ACTIVITĂŢI DESFĂŞURATE ÎN CADRUL STAGIULUI DE DOCTORAT

Lucrări publicate în reviste internaţionale cotate ISI:

1. *Apolipoprotein E - A Multifunctional Protein with Implications in Various Pathologies as a Result of Its Structural Features*. (Review) ***Tudorache IF**, *Trusca VG, Gafencu AV.Comput Struct Biotechnol J. 2017 Jun 6;15:359-365. doi: 10.1016/j.csbj.2017.05.003. eCollection 2017. PMID: 28660014

A. Introduction and Objectives

Cardiovascular diseases (CVDs) are the leading cause of mortality in Romania, responsible for over 55% of annual deaths (National Institute of Public Health, 2024). In this context, atherosclerosis (AS), a chronic inflammatory condition of the vascular wall, plays a central role in the development of acute cardiovascular complications such as myocardial infarction or stroke. Although conventional therapies such as statins and antithrombotic agents reduce the incidence of cardiovascular events, they fail to effectively address persistent vascular inflammation, an essential component of atherosclerotic plaque progression (d'Aiello et al., 2024).

In particular, it has been shown that the failure of inflammation resolution, an active and coordinated physiological process, contributes significantly to plaque instability and disease progression (Fredman, 2019). In this context, specialized pro-resolving mediators (SPMs), such as resolvins or lipoxins, represent an emerging class of molecules capable of restoring vascular homeostasis by actively inducing inflammation resolution. However, the therapeutic use of SPMs is limited by their low stability in circulation and poor bioavailability at the site of the atherosclerotic lesion (Fredman & Serhan, 2024).

In parallel, natural compounds such as protocatechuic acid (PCA), with anti-inflammatory and antioxidant roles, have been proposed as adjuvants in combating endothelial and macrophage inflammation. Nevertheless, their therapeutic efficacy is limited by low bioavailability and nonspecific targeting (Cory et al., 2018). Nanotechnology offers an innovative solution to these challenges, facilitating targeted delivery and protection of compounds of interest in stable pharmaceutical forms (Ahmad et al., 2022).

Based on these premises, **the main objective of this doctoral thesis** was the development and characterization of **innovative nanotherapeutic platforms** for combating vascular inflammation in AS, with the following complementary mechanisms: (1) active induction of inflammation resolution by delivering SPMs or (2) inhibition of pro-atherogenic inflammatory pathways by delivering PCA.

The following specific **objectives** were proposed and achieved:

1. Characterization and testing of dextran-coated magnetic nanoparticles loaded with protocatechuic acid (MNP-Dex/PCA), aimed at inhibiting vascular inflammation by

reducing the expression of pro-inflammatory cytokines and monocyte adhesion to activated endothelial cells (ECs), in *in vitro* cellular models.

2. Development and characterization of biomimetic nanoparticles loaded with SPMs (Bio-LN/SPM) and testing their in vitro effects on the inflammatory phenotype of ECs, macrophages (Mφ), and smooth muscle cells (SMCs) involved in AS pathogenesis.

3. Evaluation of the biodistribution and acute effects of Bio-LN/SPM nanoparticles in a murine model of AS (hyperlipidemic ApoE$^{-/-}$ mice), by analyzing accumulation in the aorta, changes in the composition of circulating immune cells, and the inflammatory cytokine profile at 24 hours after administration.

4. Validation of the preclinical efficacy of the pro-resolving nanotherapeutic strategy in AS, in the ApoE$^{-/-}$ murine model, by demonstrating the therapeutic effect of Bio-LN/SPM nanoparticles on atherosclerotic lesions at two plaque progression stages, with emphasis on reducing vascular inflammation and lipid accumulation in the aorta and aortic root.

B. Structure of the thesis

The doctoral thesis is structured into two major parts:

Part I – Current state of the art includes an analysis of the literature regarding the role of inflammation in atherosclerosis (AS), the molecular mechanisms involved in its resolution, and emerging nanotherapeutic strategies that can positively influence disease progression. This part comprises six chapters that provide a solid theoretical basis for developing the two experimental directions.

Chapter 1 presents the structural and functional organization of the cardiovascular system, with emphasis on the architecture of the arterial wall and the critical role of ECs in maintaining vascular homeostasis. Imbalances that can disrupt endothelial function and contribute to the onset of vascular pathologies, such as AS, are discussed.

Chapter 2, "Inflammation in Atherosclerosis," systematically details the stages of atherosclerotic lesion progression, from endothelial activation and LDL accumulation in the

subendothelial space to foam cell formation, necrotic core development, and plaque rupture. It highlights the inflammatory processes that increase plaque vulnerability and the involved cellular elements.

Chapter 3 is dedicated to the concept of "Resolution of inflammation" as an active process with complex regulatory mechanisms, distinct from classical inflammation inhibition. A complete conceptual framework of specialized pro-resolving mediators (SPMs) such as lipoxins, resolvins, maresins, and protectins is presented, emphasizing their role in restoring tissue homeostasis. An extensive synthesis of the classes, functions, mechanisms of action, and receptors of these mediators is detailed in this chapter, forming the theoretical foundation for the pro-resolving pharmacological strategies proposed later in the experimental part of the thesis.

Chapter 4 highlights the limitations of current conventional therapies, which mainly target lipid lowering or suppression of the inflammatory response. These strategies fail to prevent the progression of atherosclerotic lesions and do not address the cause of persistent inflammation. Thus, the need for innovative therapeutic interventions capable not only of inhibiting inflammation but also activating physiological resolution mechanisms is justified, promoting restoration of vascular homeostasis.

Chapter 5 introduces the field of nanomedicine, focusing on nanotherapy applied to CVDs. The types of nanoparticles used in this context are detailed, emphasizing targeted delivery advantages and functionalization strategies designed to increase therapeutic efficacy. The concept of biomimetic nanoparticles is also presented, highlighting their potential to mimic natural cellular components to facilitate specific recognition of inflamed tissues and improve targeted distribution of therapeutic agents.

Chapter 6 explores direct applications of SPMs and their synthetic analogues in chronic inflammation and AS. It describes preclinical studies and potential research directions in which SPMs are considered promising therapies with mechanisms complementary to traditional anti-inflammatory drugs.

Part II – Original contributions is dedicated to the experimental studies performed, divided into two distinct nanotherapeutic directions:

Chapter 1 describes the development, characterization, and *in vitro* evaluation of dextran-coated magnetic nanoparticles loaded with protocatechuic acid (MNP-Dex/PCA). The study demonstrates the effectiveness of these nanoparticles in reducing pro-inflammatory cytokine expression in ECs and M1-type macrophages. Additionally, MNP-Dex/PCA inhibit NF-κB and MAPK signaling pathways and reduce monocyte adhesion to activated endothelium, supporting their potential in vascular inflammation therapy.

Chapter 2 is dedicated to a comprehensive study comprising experimental sections that promote active resolution of inflammation using biomimetic nanoparticles loaded with specialized pro-resolving mediators (Bio-LN/SPM).

- Section 1 presents the biomimetic nanoparticle synthesis process and physicochemical characterization, including composition, size, and zeta potential evaluation.
- Section 2 analyzes the *in vitro* effects of these nanoparticles on AS-relevant cell lines (ECs, Mφ, and SMCs). A significant reduction in inflammatory marker expression and promotion of an anti-inflammatory phenotype were observed.
- Section 3 focuses on the *in vivo* testing of Bio-LN/SPM in the $ApoE^{-/-}$ murine model, 24 hours post-injection. Nanoparticle distribution and acute effects on the immune profile were evaluated.
- Section 4 investigates the therapeutic impact of Bio-LN/SPM on atherosclerotic lesions in $ApoE^{-/-}$ mice at two different progression stages (4 weeks and 8 weeks of high-fat diet), highlighting reductions in systemic and local inflammation and lipid accumulation, as well as induction of a pro-resolving phenotype in plaque-associated Mφ.

Thus, the structure of the thesis reflects an integrated and progressive approach, from a detailed understanding of AS pathology and molecular processes involved in inflammation and resolution, to the experimental development and validation of innovative therapeutic solutions. Each chapter logically and scientifically contributes to strengthening the research hypothesis and demonstrating the applicability of nanomedicine in personalized treatment of vascular inflammation associated with AS.

C. Main results and conclusions:

1. Development of MNP-Dex/PCA magnetic nanoparticles as theranostic vehicles combining diagnosis and therapy in a single platform

- Stable colloidal nanoparticles were obtained, in which PCA was efficiently adsorbed onto the nanoparticle surface and maintained in active form.
- MNP-Dex/PCA were efficiently taken up by endothelial cells and pro-inflammatory M1 macrophages, without cytotoxic effects at concentrations < 100 μg/mL.
- Treatment with MNP-Dex/PCA led to:
    - Inhibition of inflammatory signaling pathways NF-κB and MAPK with reduced expression of IL-1β, TNF-α, IL-6, MCP-1, p38, and ERK1/2.
    - Decreased monocyte adhesion to activated endothelium.

These data confirm the potential of these nanoparticles to inhibit the vascular inflammatory response, opening the possibility of their use in preventing the progression of atherosclerotic plaque.

2. Development and preclinical validation of biomimetic nanoparticles loaded with specialized pro-resolving mediators in a murine model of atherosclerosis

- Nanoemulsions coated with cellular membranes were obtained to mimic the structure of circulating monocytes, with SPMs as active cargo (Bio-LN/SPM).
- *In vitro*, Bio-LN/SPM:
    - Reduced inflammatory marker expression (VCAM-1, MCP-1, NLRP3, IL-1β),
    - Promoted a pro-resolving M2 phenotype in macrophages (decreased iNOS and increased phagocytic capacity),
    - Decreased monocyte adhesion and transmigration through activated endothelium.
- *In vivo* (ApoE$^{-/-}$ mice fed a high-fat diet):
    - Intravenous administration of Bio-LN/SPM led, after 24 hours, to:
        - Reduction of circulating monocytes and neutrophils,
        - Decreased plasma levels of cytokines (IFN-γ, CXCL10, IL-16, TIMP-1, and TNF-α) and chemokines (MCP-1 and C5a),
        - Selective accumulation in the aorta

- Repeated administration at two different stages of plaque progression demonstrated:
  - Reduced systemic inflammation and modulation of circulating immune populations,
  - Decreased local inflammation and induction of a pro-resolving M2 phenotype in aortic macrophages, shown by increased expression of CD206 and MerTK markers, along with decreased iNOS levels,
  - Reduced lipid accumulation in lesions

These results confirm that Bio-LN/SPM not only inhibit inflammation but also promote its resolution, reprogramming the immune phenotype and the aortic microenvironment.

D. Original contributions of the thesis

1. Development of two nanotherapeutic platforms with complementary mechanisms, validated in vitro or in vivo, for combating vascular inflammation:

a) MNP-Dex/PCA – anti-inflammatory effect via inhibition of NF-κB and MAPK (Figure 1).

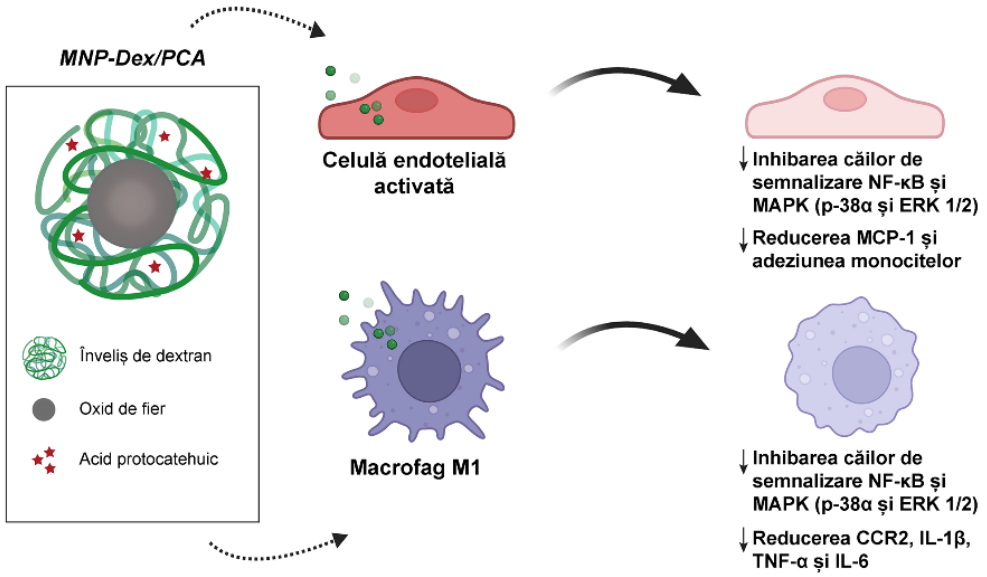

Figure 1. Nanotherapeutic strategy developed in the first study for combating vascular inflammation associated with AS. The scheme illustrates the mechanism of action of dextran-coated magnetic nanoparticles loaded with protocatechuic acid (MNP-Dex/PCA), which are internalized by ECs and M1-type MΦ, leading to inhibition of inflammatory signaling pathways (NF-κB and MAPK p38α and ERK1/2) and reduced monocyte adhesion.

b) Bio-LN/SPM – pro-resolving effect, via induction of an M2 phenotype in macrophages, decreased inflammatory markers, and reduced lipid deposits in the atherosclerotic plaque (Figure 2).

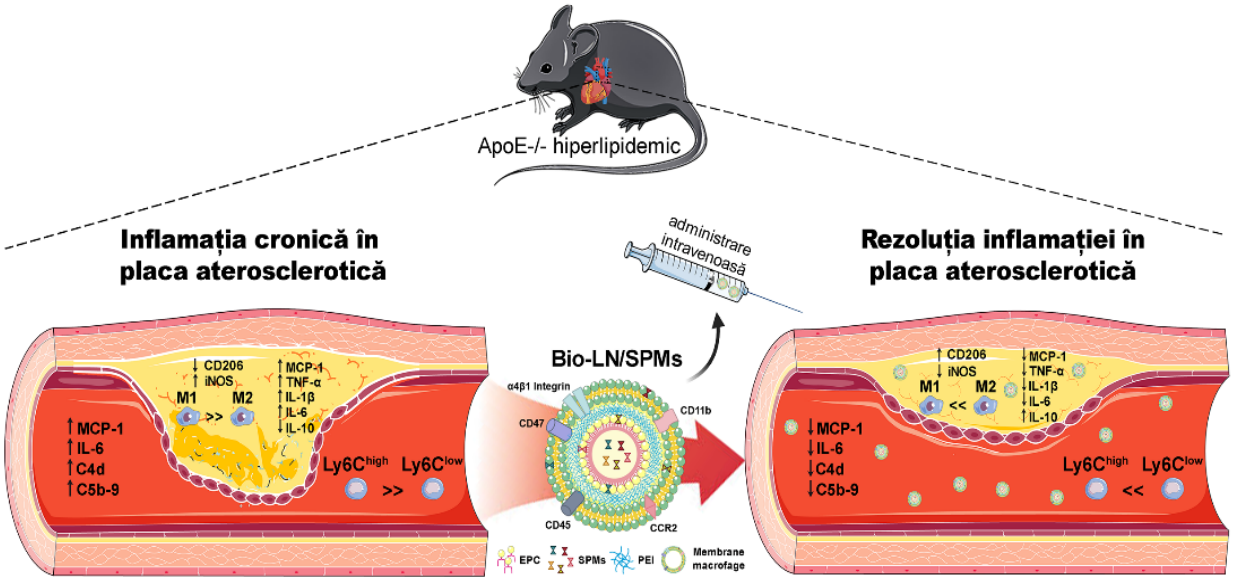

Figure 2. Schematic representation of the nanotherapeutic strategy developed in the second study to promote the resolution of vascular inflammation associated with AS. The effect of biomimetic nanoparticles loaded with specialized pro-resolving mediators (Bio-LN/SPM) on ECs, vascular SMCs, and MΦ in the hyperlipidemic ApoE−/− murine model is illustrated. Treatment with Bio-LN/SPM results in reduced expression of circulating and local inflammatory markers, induction of a reparative phenotype in MΦ, and decreased lipid accumulation in atherosclerotic lesions.

2. Confirmation of the role of inflammation resolution in AS control and validation of SPMs as viable therapeutic agents in cardiovascular nanomedicine.

E. General conclusions

This thesis makes a significant contribution to understanding and treating chronic vascular inflammation in the context of AS, proposing two complementary nanotherapeutic approaches. While MNP-Dex/PCA inhibit pro-atherogenic inflammatory pathways, Bio-LN/SPM actively promote inflammation resolution—a key process largely overlooked in current treatments. Through these strategies, the work demonstrates the applicability of nanomedicine in personalized cardiovascular therapy, opening new avenues for early and targeted intervention in AS.

II. Introduction and Objectives

Non-coding ribonucleic acids (ncRNAs) represent essential components of genomic regulatory architecture, participating in the control of gene expression at epigenetic, transcriptional, and post-transcriptional levels (Esteller, 2011; Statello et al., 2021). MicroRNAs (miRs) constitute a subclass of small ncRNAs (≈21–23 nucleotides) that regulate gene expression post-transcriptionally through interaction with the 3′UTR region of target messenger RNAs, leading to translational repression and/or transcript degradation (Bartel, 2009; He and Hannon, 2004). Through partial complementarity, a single miR can simultaneously modulate the expression of multiple transcripts, contributing to fine-tuning of gene expression programs.

Hypoxia represents a stress condition of major pathophysiological relevance, present in acute and chronic inflammation, tissue ischemia, and cardiovascular pathology (Eltzschig and

Carmeliet, 2011; Colgan et al., 2020). Cellular response to reduced oxygen availability is coordinated by hypoxia-inducible factors (HIF), which modulate the expression of genes involved in energy metabolism, angiogenesis, and cell survival (Semenza, 2012; Bakleh and Al Haj Zen, 2025). HIF stabilization (Epstein et al., 2001; Bruick and McKnight, 2001) triggers an adaptive transcriptional program characterized by metabolic reprogramming and adjustment of mitochondrial function.

In this context, miR-210 has been identified as a central regulator of cellular response to hypoxia, being directly controlled by HIF through binding to evolutionarily conserved hypoxia-responsive elements (HRE) (Chan et al., 2012; Semenza, 2012). Functionally, miR-210 modulates the expression of genes involved in mitochondrial metabolism, angiogenesis, DNA repair, and cell cycle regulation, contributing to the integration of metabolic adaptation with cell survival mechanisms under hypoxic conditions (Chan et al., 2009; Devlin et al., 2011; He et al., 2012). The genomic organization of the miR-210 locus, located within an intron of the MIR210HG gene, suggests a possible functional interdependence between miR-210 and its genomic context.

Most available studies have utilized models of transient overexpression or inhibition, without systematically evaluating the consequences of complete genomic deletion of the miR-210 locus. This limitation is relevant in the context of three-dimensional genome organization and the existence of topologically associated domains (TAD), where perturbation of a genomic locus can generate widespread transcriptomic effects beyond the targeted sequence (Dixon et al., 2012; Nora et al., 2012; Engreitz et al., 2016).

Based on these considerations, in this thesis we aimed to investigate the link between hypoxia-induced signaling and inflammation, specifically evaluating the role of the miR-210 genomic locus in relevant inflammatory contexts. The doctoral thesis is based on the hypothesis that genomic deletion of the miR-210 locus determines perturbations in transcriptomic networks involved in cellular adaptation to hypoxia, through mechanisms that could reflect both the absence of mature miR-210 and disruption of the local genomic context associated with the MIR210HG locus. In this context, the main goal of the thesis was, on one hand, to investigate the functional and transcriptomic consequences of miR-210 deletion at the cellular level, and on the other hand, to investigate the consequences of miR-210 locus manipulation on genomic stability. To achieve this goal, the following specific objectives were established: (i)

characterization of transgenic mice (mice with constitutive miR-210 deletion and mice with inducible miR-210 overexpression); (ii) generation and validation of cellular models with miR-210 locus deletion; (iii) comparative evaluation of transcriptomic response in WT and miR-210 KO cells; (iv) identification of genes and biological pathways modified following miR-210 deletion or MIR210HG locus disruption; (v) analysis of the impact of deletion on functional effects of miR-210 locus loss.

The novelty of this thesis consists in the systematic analysis of the effects of complete genomic deletion of the miR-210 locus under normoxic and hypoxic conditions, in an experimental framework that allows distinguishing between the consequences of loss of the mature miR and possible effects associated with perturbation of the local genomic context (MIR210HG). The thesis demonstrates that the miR-210 locus functions in interaction with adjacent genetic elements and underscores the importance of considering genomic localization and structural characteristics of each non-coding RNA locus in loss-of-function experiments performed through genome editing technologies.

Furthermore, evaluation of these effects in physiologically relevant primary cells (fibroblasts, macrophages, HEK cells) strengthens the biological relevance of the observations and provides a robust interpretative framework for the identified transcriptomic changes. By integrating transgenic mouse models, primary cells, and genetically modified cell lines, the thesis proposes a unified perspective on the role of miR-210 at the interface between hypoxia and inflammation.

III. Thesis Structure

The doctoral thesis is structured in two major parts:

Part I – State of the Art comprises an analysis of the specialized literature regarding the role of hypoxia in regulating cellular response, the functional interaction between hypoxia and inflammation, as well as post-transcriptional regulation mechanisms mediated by non-coding RNAs, with emphasis on microRNAs and, particularly, on miR-210. This part is structured in three main chapters, which provide the theoretical framework necessary for developing the experimental directions of the thesis. In **Chapter 1**, the molecular mechanisms through which hypoxia modulates inflammatory response are presented, with emphasis on the role of

hypoxia-inducible factors and their interaction with inflammatory signaling pathways. Multiple cell types involved in inflammation are analyzed, including macrophages, fibroblasts, and mesenchymal stromal cells, as well as how these respond to hypoxic stress (Davidson et al., 2021; Bernardo and Fibbe, 2013). The chapter highlights that hypoxia and inflammation represent interdependent biological processes, which mutually influence each other through common molecular and cellular mechanisms. **Chapter 2** presents the general mechanisms of post-transcriptional regulation mediated by ncRNAs, with emphasis on their classification and the role of microRNAs in controlling gene expression. The processes of microRNA biogenesis are described (Bartel, 2004), their mechanisms of action and impact on transcriptomic networks, underscoring their role in fine-tuning of biological processes, including in contexts of cellular stress such as hypoxia and inflammation. **Chapter 3** is dedicated to the analysis of miR-210, considered a central regulator of response to hypoxia. The mechanisms of miR-210 expression regulation by HIF are presented, the genomic organization of the MIR210HG locus and its functions in controlling cellular processes, including mitochondrial metabolism, angiogenesis, genomic stability, and immune response regulation. The chapter highlights the role of miR-210 as an integrator element of hypoxic and inflammatory signaling. Through integration of these chapters, a conceptual framework is outlined in which miR-210 is positioned at the interface between hypoxia and inflammation, constituting a potential key regulator of cellular adaptation to stress.

Part II – Original Contributions is dedicated to experimental studies conducted to investigate the role of miR-210 and its genomic locus in regulating cellular response to hypoxia and inflammation, utilizing transgenic mouse models and multiple physiologically relevant cell types. **Chapter 1** is dedicated to the characterization of transgenic mouse models used in the studies. The mice were obtained from our collaborators, the miR-210 OE model from Prof. Dr. Fabio Martelli (Policlinico San Donato, Italy), and the miR-210 KO model from Prof. Dr. Mircea Ivan (Indiana University, USA). The strategies for generating the animal models (constitutive deletion, respectively inducible overexpression of miR-210) and methods for characterization and molecular validation of the two lines are presented. This chapter establishes the experimental framework necessary for investigating the consequences of miR-210 loss or overexpression in vivo and ex vivo. **Chapter 2** analyzes the role of miR-210 in fibroblasts, with emphasis on transcriptomic and functional changes associated with its

deletion. Cellular responses are investigated under normoxic and hypoxic conditions, highlighting the impact on proliferation and metabolic adaptation processes. **Chapter 3** analyzes the behavior of mesenchymal stromal cells under conditions of inflammation and hypoxia, with emphasis on survival, proliferation, and activation of immunomodulatory programs. The effects of pro-inflammatory stimuli on cell viability, expression of genes involved in immunomodulatory function, and nitric oxide production are evaluated. Furthermore, the impact of the association between inflammation and hypoxia on MSC survival is investigated, highlighting that this microenvironment negatively affects the homeostasis and function of these cells. **Chapter 4** investigates the role of miR-210 in macrophages, with emphasis on their polarization and regulation of inflammatory response. miR-210 KO macrophages are analyzed, highlighting the disruption of anti-inflammatory polarization and favoring of a pro-inflammatory phenotype in the absence of miR-210. **Chapter 5** is dedicated to the study of the role of the miR-210 genomic locus in human cell lines (HEK293T) modified by genome editing. The consequences of deletion on gene expression and cellular processes are analyzed, including proliferation, mitotic spindle organization, and genomic stability. The results suggest that the observed effects are not limited to the absence of mature miR-210, but also reflect perturbation of the genomic context of the MIR210HG locus.

Thus, the structure of this part reflects a progressive approach, from validation of experimental models to functional and transcriptomic analysis in different cell types. Integration of the obtained results highlights that miR-210 acts as a regulator of cellular adaptation to hypoxia and of inflammatory response, and the effects of its deletion cannot be attributed exclusively to the loss of the mature miR, but also include consequences associated with perturbation of the genomic context of the MIR210HG locus.

IV. Principal Results

Chapter 1. Characterization of Transgenic Mouse Models for miR-210 Study

An important first result of the thesis was represented by validation and characterization of the two transgenic mouse models used for studying miR-210 function: the constitutive miR-210

deletion model (miR-210 KO) and the inducible miR-210 overexpression model (miR-210 OE). In the case of the miR-210 KO model, genotyping allowed clear differentiation of WT, heterozygous, and homozygous animals, based on the PCR products obtained; and the absence of miR-210 expression was confirmed by RT-qPCR in both the left ventricle and macrophages derived from bone marrow.

In parallel, the miR-210 OE model allowed controlled induction of miR-210 expression through the Tet-On system, with integration of the transgene at the ROSA26 locus. Doxycycline administration resulted in significant increase in miR-210 expression in heart and skeletal muscle, in a dose-dependent manner, confirming the functionality of the model in vivo. However, studies conducted on cells isolated from these animals revealed the transient nature of overexpression and the inability to efficiently reactivate the Tet-On system in culture, suggesting the existence of specific constraints of the in vivo environment. Overall, this chapter provided the experimental models and methodology necessary for evaluating the role of miR-210 in different cell types and biological contexts.

Chapter 2. Transcriptomic and Functional Changes in Fibroblasts with miR-210 Deletion

In this chapter, the impact of miR-210 deletion on metabolism and function of fibroblasts was studied, using mouse dermal fibroblasts isolated from transgenic mice. Validation of deletion demonstrated complete absence of miR-210 expression in KO fibroblasts, both in normoxia and in hypoxia, while WT fibroblasts showed pronounced induction of miR-210 under hypoxic conditions. Comparative transcriptomic analysis of miR-210 KO fibroblasts highlighted significant changes in biological pathways associated with oxidative phosphorylation, glycolysis, fatty acid metabolism, mTORC1 signaling, and response to hypoxia, supporting the role of miR-210 in integrating metabolic adaptation to hypoxic stress.

A notable result was the identification of expression changes at the level of genes located in genomic proximity to the miR-210 locus, including Rassf7, Rnh1, Taldo1, and Cd151, suggesting that deletion of this locus can affect not only the function of the mature microRNA, but also local transcriptional regulation within the genomic domain containing it.

From a functional perspective, miR-210 KO fibroblasts showed significant reduction in maximal respiratory capacity and mitochondrial respiratory reserve (Figure 1a), as well as

increased mitochondrial ROS in hypoxia. Furthermore, cell cycle analysis revealed redistribution of cells between cell cycle phases, characterized by accumulation in S phase and reduction of the proportion of cells in G0/G1 phase, suggesting dysregulation of the G1/S transition and disruption of correct cell cycle progression, associated with diminished cell proliferation rate (Figure 1b). These data demonstrate that miR-210 contributes to maintenance of mitochondrial homeostasis, redox balance, and correct cell cycle progression in fibroblasts, especially under hypoxic stress conditions.

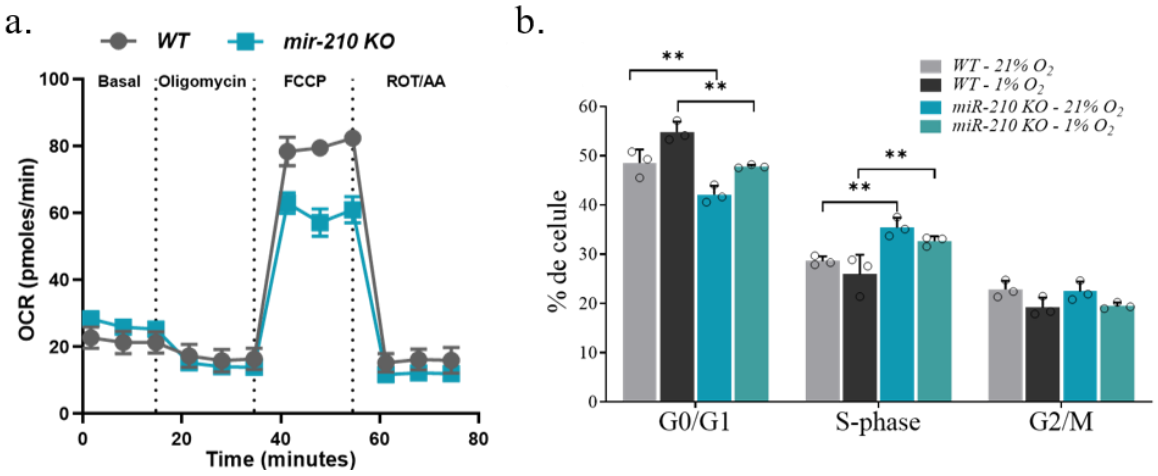

***Figure 1**. OCR profile in WT and miR-210 KO fibroblasts and cell cycle analysis in WT and miR-210 KO fibroblasts under normoxia (21% O_2) and hypoxia (1% O_2). (a) Temporal representation of OCR dynamics measured by Seahorse Mito Stress test under basal conditions and after addition of inhibitors. (b) Quantitative representation of the percentage of cells in G0/G1, S, and G2/M phases. Data are expressed as mean ± SD. Statistical analysis: two-way ANOVA; **p < 0.01. (Figure adapted from Preda et al., 2025)*

Chapter 3. Behavior of Mesenchymal Stromal Cells in Inflammation and Hypoxia

This chapter aimed to investigate how the inflammatory and hypoxic microenvironment influences the phenotype and survival of mesenchymal stromal cells (MSC), considering their central role in regulating inflammation and tissue regeneration. The results showed that inflammatory stimulation activates the immunomodulatory programs of MSC, evidenced by increased expression of IDO1, NOS2, and COX2 genes. At the same time, TNF-α inhibited

proliferation in a dose-dependent manner, and the association of TNF-α and IFN-γ amplified this effect, inducing morphological changes compatible with cellular stress and cell death.

An important result was the demonstration that inflammatory activation of MSC is accompanied by a significant increase in nitric oxide production, and inhibition of NOS2 partially ameliorated cell viability, suggesting the involvement of excess NO in the observed cytotoxicity. Under moderate hypoxic conditions, MSC initially maintained viability; however, the association of hypoxia with inflammatory stimuli resulted in pronounced reduction of cell survival. Overall, the obtained data show that the interaction between inflammation and hypoxia compromises MSC function and viability, through excessive activation of NOS2-dependent pathways and through disruption of redox homeostasis. These results underscore the importance of optimizing preconditioning and culture conditions for therapeutic use of MSC in inflammatory and hypoxic contexts.

Chapter 4. Role of miR-210 in Modulating Macrophage Function in Inflammation

In this chapter, the role of miR-210 in regulating the function of bone marrow-derived macrophages was analyzed, with emphasis on functional polarization, metabolic profile, and inflammatory response. Monocytes isolated from bone marrow were differentiated into M0 macrophages and subsequently polarized toward the M2 phenotype. The analyses performed showed that macrophages from miR-210 KO mice present an accentuated inflammatory profile in the basal state and a deficient transition toward the M2 phenotype. Transcriptomic analysis indicated significant changes in gene expression in both M0 and M2 macrophages, and bioinformatic analyses highlighted activation of pathways involved in response to oxidative stress, hypoxia, and inflammation, concomitantly with reduced expression of genes associated with interferon-dependent response and IL-6/STAT3 signaling (Figure 2a,b).

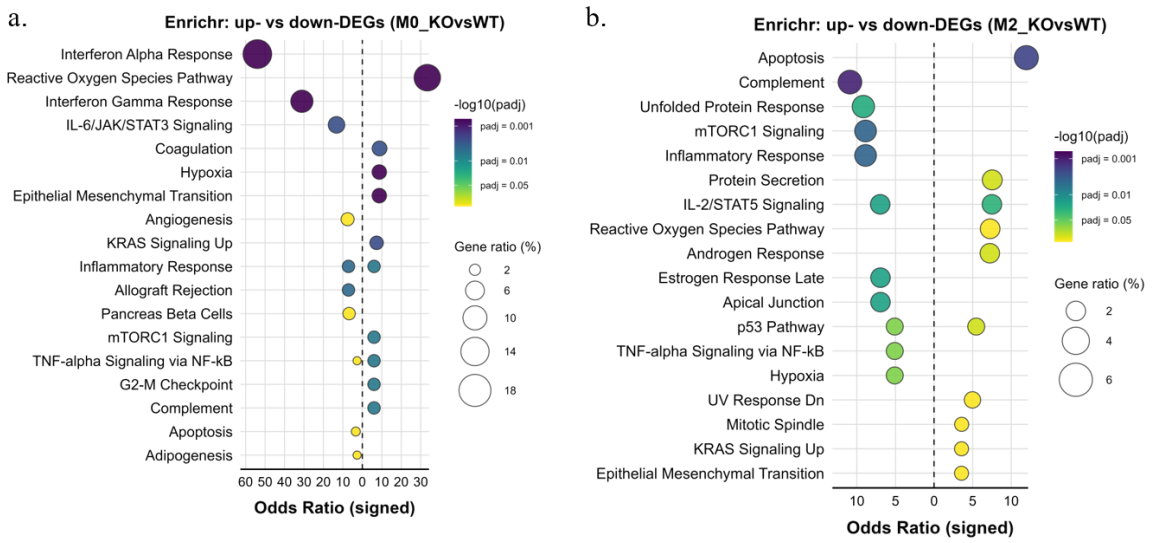

Figure 2. *Effects of miR-210 deletion in M0 and M2 macrophages. Dot-plot representations obtained with the Enrichr platform, highlighting biological pathways significantly enriched among differentially expressed genes (DEG) between macrophages from miR-210 KO and WT mice: (a) in M0-type macrophages and (b) in M2-type macrophages (adapted from Neculachi et al., 2025).*

These results were functionally confirmed by increased secretion of IL-6, TNF-α, and IL-1β in miR-210 KO M0 macrophages and by accumulation of pro-IL-1β precursor, indicating intrinsic inflammatory activation in the absence of this microRNA. Under M2 polarization conditions, KO macrophages showed incomplete reprogramming, with reduction of M2 markers, activation of pro-apoptotic pathways, and increased susceptibility to apoptosis following TNF-α stimulation. Furthermore, increased levels of p53, TGF-β, and MMP-9 proteins were demonstrated, suggesting activation of programs associated with cellular stress and tissue remodeling. Metabolic analysis showed that M0 KO macrophages have reduced basal glycolytic activity, and functional tests demonstrated increased phagocytic and efferocytic activity (Figure 3a,b). Overall, the results demonstrate that miR-210 acts as an integrative regulator of metabolism and inflammation in macrophages, contributing to maintenance of balance between inflammatory activation, survival, and alternative polarization

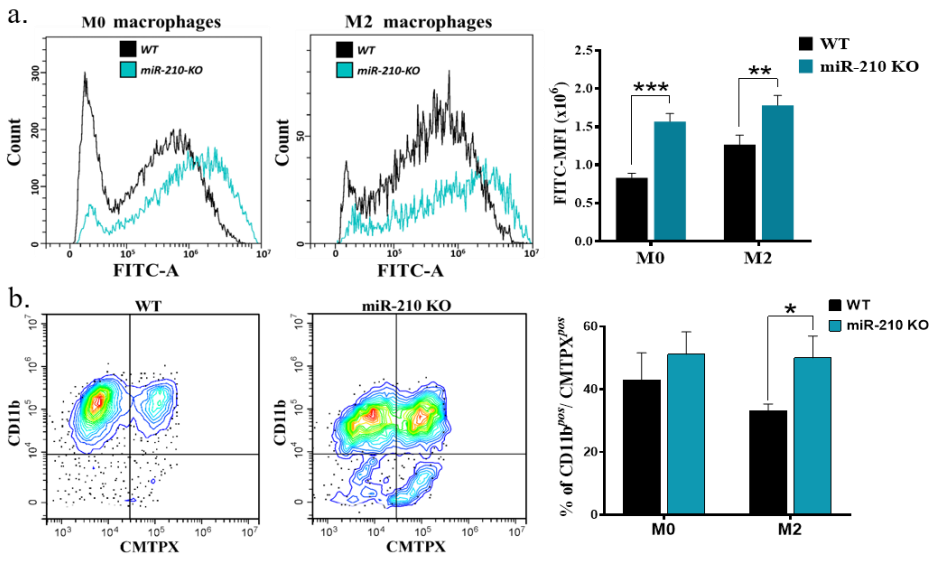

Figure 3. *Functional characterization of miR-210 KO macrophages. (a) Phagocytic capacity of M0 and M2 macrophages (flow cytometry), quantified as FITC-MFI (n = 6/condition). (b) Efferocytic capacity of WT and miR-210 KO macrophages, quantified as percentage of CD11b⁺CMTPX⁺ cells under M0 and M2 conditions (n=3/condition). Data are expressed as mean ± SEM. Statistical analysis: two-way ANOVA, **p < 0.01, ***p < 0.001 (adapted from Neculachi et al., 2025).*

Chapter 5. Impact of miR-210 Deletion on the Transcriptome in HEK293T Cells

To evaluate the role of the miR-210 locus in a human genomic context, an experimental model was developed based on HEK293T cells, in which two types of knockout clones were generated: clones with deletion of the pre-miR-210 sequence and clones with extended deletion of the MIR210HG locus. Molecular validation confirmed the absence of miR-210 expression and MIR210HG host transcript in hypoxia. Transcriptomic analysis by RNA-seq revealed consistent changes in gene expression in knockout cells, affecting especially pathways involved in adaptation to hypoxia, cell cycle regulation, mTORC1 signaling, response to cellular stress, NF-κB activation, and response to proteotoxic stress. These results show that deletion of the miR-210 locus perturbs cellular adaptation programs to hypoxia and affects mechanisms of proliferation control.

A notable result of this chapter was the demonstration of the existence of a local, cis-type effect on the expression of genes located in the vicinity of the MIR210HG locus. Genes localized within an interval of approximately 400–500 kb around the locus showed expression changes, and analysis of chromatin interactions, using publicly available Hi-C data, suggested integration of the region into a topologically associated domain (TAD). These data support the hypothesis that deletion of the miR-210 locus can alter local chromatin architecture and cis-regulatory interactions in the region. Functional tests showed that deletion of the miR-210 locus reduces proliferative capacity and affects mitochondrial respiration, and cell cycle analysis indicated a delay in G1/S transition in hypoxia.

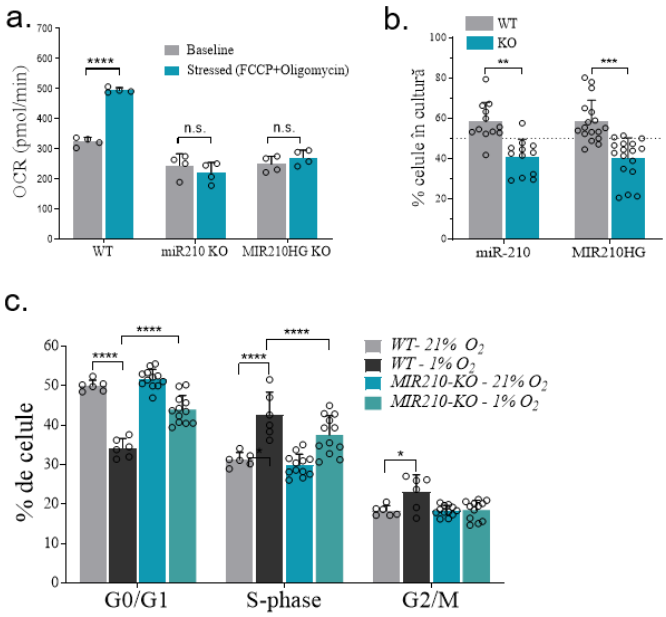

Figure 4. *Functional consequences of miR-210 locus deletion in HEK293T cells. (a) Changes in OCR in HEK clones, measured under basal and stress conditions. (b) Competitive proliferation tests between WT clones marked with GFP and miR210-KO or MIR210HG-KO marked with dTomato, analyzed after 3 days of co-culture. (c) Analysis of cell cycle distribution in HEK cells cultured under normoxic and hypoxic conditions. Statistical analysis was performed using two-way ANOVA test, and statistical significance is represented as follows: *p < 0.05, **p < 0.01, ***p < 0.001, ****p < 0.0001 (Figure adapted from Preda, M.B., 2025).*

Overall, these results demonstrate that the phenotype associated with miR-210 locus deletion cannot be explained exclusively by the loss of mature miR-210, but also reflects perturbation of an integrated genomic unit, which includes the MIR210HG host transcript and local regulatory elements.

V. General Conclusions

The results of this thesis demonstrate that miR-210 functions as an integrative regulator at the interface between hypoxia and inflammation. In both fibroblasts and human HEK293T cells, deletion of miR-210/its locus results in a common dysregulation of cellular adaptation to hypoxia: disruption of metabolic programs and mitochondrial function (reduction in respiratory capacity), alteration of cell cycle progression at the G1/S transition, and affecting transcriptional programs of hypoxia response. Furthermore, in both models deletion produces a local, cis-type effect: genes neighboring the locus are modified (Rassf7, Rnh1, Taldo1, Cd151), integrated within a topologically associated domain (TAD) — which shows that the miR-210/MIR210HG locus behaves as an integrated genomic unit, with the phenotype of deletion not being explainable exclusively by the loss of the mature microRNA. In macrophages, miR-210 maintains the balance between inflammatory activation and reparatory polarization: its absence results in a pro-inflammatory basal phenotype (IL-6, TNF-α, IL-1β) and incomplete M2 reprogramming, accompanied by activation of cellular stress programs (p53, TGF-β, MMP-9), positioning miR-210 as an integrative regulator of metabolism and inflammatory response. Overall, the functional consequences of miR-210 loss reflect both the absence of the mature miR and perturbation of local chromatin architecture.

VI. Original Contributions of the Thesis

1. Characterization and molecular validation of two complementary transgenic mouse models for functional study of miR-210 - constitutive deletion (KO) and inducible Tet-On/ROSA26 overexpression (OE), through genotyping and RT-qPCR in tissues and derived primary cells.

2. Demonstration of dose-dependent induction of miR-210 in vivo in the OE model and of the transient nature of overexpression in culture.

3. Identification, in fibroblasts with miR-210 deletion, of a transcriptomic signature of metabolic dysregulation (oxidative phosphorylation, glycolysis, fatty acid metabolism, mTORC1 signaling, and response to hypoxia).

4. Demonstration of reduction in maximal respiratory capacity and mitochondrial respiratory reserve, accompanied by increased mitochondrial ROS in hypoxia, in miR-210 KO fibroblasts.

5. Demonstration of cell cycle perturbation in KO fibroblasts (accumulation in S phase, reduction of G0/G1 fraction, and dysregulation of G1/S transition), with diminished proliferation rate.

6. Identification of a local effect of deletion on genes neighboring the miR-210 locus (Rassf7, Rnh1, Taldo1, Cd151), indicating perturbation of transcriptional regulation within the genomic domain containing it.

7. Demonstration of an accentuated pro-inflammatory basal phenotype in miR-210 KO M0 macrophages (increased secretion of IL-6, TNF-α, and IL-1β and accumulation of pro-IL-1β precursor).

8. Demonstration of deficient reprogramming toward the M2 phenotype in KO macrophages (reduction of M2 markers, increased susceptibility to apoptosis following TNF-α, and increased p53, TGF-β, and MMP-9).

9. Demonstration of reduced basal glycolytic activity and increased phagocytic and efferocytic capacity in miR-210 KO macrophages, positioning miR-210 as an integrative regulator of metabolism and inflammation.

10. Development of a human cell model (HEK293T) with deletion of either the pre-miR-210 sequence or the entire MIR210HG locus, through genome editing.

11. Demonstration, by RNA-seq, of perturbation of adaptation programs to hypoxia, cell cycle regulation, mTORC1 and NF-κB signaling, and response to proteotoxic stress in HEK293T KO clones.

12. Identification of a cis effect on expression of genes located at ~400–500 kb from the locus and, through integration of Hi-C data, placement of the region within a topologically associated domain (TAD), supporting the concept that the miR-210/MIR210HG locus functions as an integrated genomic unit.

Posters Presented at International Scientific Events

1. Neculachi CA, Nastase-Rusu EG, Zaccagnini G, Martelli F, Burlacu A, Preda MB. The role of hypoxamir-210 on macrophage behaviour. Poster presentation, International Conference and XXXIX Scientific Session of the Romanian Society for Cell Biology, Cluj-Napoca, Romania, October 21–23, 2022.

2. Neculachi CA, Nastase-Rusu EG, Marinescu-Colan CI, Preda MB, Burlacu A. MiR-210 deficiency enhances pro-inflammatory activation and disrupts M2 macrophage differentiation in murine models. Poster presentation, 42nd Annual Scientific Session of the Romanian Society for Cell Biology, Bucharest, Romania, November 20–21, 2025.

3. Neculachi CA, Nastase-Rusu EG, Cherry L, Marinescu-Colan CI, Tastsoglou S, Cosman BP, Simionescu M, Martelli F, Preda MB, Burlacu A. MiR-210 is required for complete

polarisation of M2 macrophages. Poster presentation, CBFH Biennial Meeting – ESC Working Groups on Cellular Biology of the Heart and Myocardial Function, Naples, Italy, November 26–28, 2025.1.

Oral presentations at international scientific conferences

1. Neculachi CA. Oral presentation, 9th COST Action CardioRNA MC and WG Meeting, "miR-210 at the overlap between hypoxia signalling and inflammatory pathways in macrophage biology", University of Nicosia, Nicosia, Cyprus, February 22–24, 2023.

International Scholarships

1. Neculachi CA. Research Mobility Scholarship – Short-Term Scientific Mission (STSM) awarded within the COST Action CA17129 – CardioRNA: Functional Significance of the Non-Coding Genome in the Cardiovascular System. Project title: miR-210 at the overlap between hypoxia signalling and inflammatory pathways in macrophage biology. Host institution: IRCCS Policlinico San Donato, Milano, Italy (coordinator: Prof. Fabio Martelli). Period: June 15, 2022 – August 31, 2022 (3 months)

Research Funding and Research Project Collaborations

1. Doctoral Scholarship – Romanian Academy (SCOSAAR), 2020–2023 (Contract No. 60/02.11.2020).

2. Collaborator – Project PNRR-III-C9-2022-I8-186: "Targeting Cardiac Fibrosis in Heart Failure: Challenges and Potential Solutions Based on ncRNA Therapeutics" (FibroThera). Project Director: Dr. Fabio Martelli (Scientific Director, Molecular Cardiology Laboratory, I.R.C.C.S. Policlinico San Donato, Italy). Period: 2023–2026.

3. Collaborator – Project PN-III-P4-ID-PCCF-2016-0172: "Targeting Innate Immune Mechanisms to Improve Risk Stratification and to Identify Future Therapeutic Options in Myocardial Infarction" (INNATE-MI). Project Director: Acad. Maya Simionescu. Period: 2020–2022.

4. Collaborator – Project PN-III-P1-1.1-TE-2019-1893: "MiR-210 Genomic Locus at the Overlap Between Hypoxia Signalling and Inflammatory Networks" (210-HINT). Project Director: Dr. Bogdan Preda. Period: 2021–2022.

Participarea în proiecte de cercetare – 5

A. Introducere și obiective

Bolile cardiovasculare (BCV) reprezintă principala cauză de mortalitate în România, responsabile pentru peste 55% dintre decesele anuale (Institutul Național de Sănătate Publică, 2024). În acest context, ateroscleroza (AS), o afecțiune cronică inflamatoare a peretelui vascular, joacă un rol central în dezvoltarea complicațiilor cardiovasculare acute, precum infarctul miocardic sau accidentul vascular cerebral. Deși terapiile convenționale, cum ar fi statinele și agenții antitrombotici, reduc incidența evenimentelor cardiovasculare, acestea nu reușesc să abordeze eficient inflamația vasculară persistentă, o componentă esențială a progresiei plăcii aterosclerotice (d'Aiello et al., 2024).

În mod particular, s-a demonstrat că eșecul rezoluției inflamației, proces fiziologic activ și coordonat, contribuie semnificativ la instabilitatea plăcilor și progresia bolii (Fredman, 2019). În acest context, mediatori specializați pro-rezoluție (SPM) precum resolvinele sau lipoxinele, reprezintă o clasă emergentă de molecule capabile să restabilească homeostazia vasculară prin inducerea activă a rezoluției inflamației. Cu toate acestea, utilizarea terapeutică a SPM este limitată de stabilitatea lor redusă în circulație și de biodisponibilitatea scăzută la locul leziunii aterosclerotice (Fredman & Serhan, 2024).

În paralel, compuși naturali precum acidul protocatehuic (PCA), cu rol anti-inflamator și antioxidant, au fost propuși ca adjuvanți în combaterea inflamației endoteliale și macrofagice. Totuși, eficacitatea lor terapeutică este limitată de biodisponibilitatea redusă și țintirea nespecifică (Cory et al., 2018). Nanotehnologia oferă o soluție inovatoare pentru aceste provocări, facilitând livrarea țintită și protejarea compușilor de interes în forme farmaceutice stabile (Ahmad et al., 2022).

Pornind de la aceste premise, **scopul principal al acestei teze de doctorat** a fost dezvoltarea și caracterizarea unor **platforme nanoterapeutice inovatoare** pentru combaterea inflamației vasculare în AS, având ca mecanisme complementare: (1) inducerea activă a rezoluției inflamației prin livrarea de SPM sau (2) inhibarea căilor inflamatoare pro-aterogene prin livrarea de PCA.

Au fost propuse și realizate următoarele **obiective specifice**:

1. Caracterizarea și testarea unor nanoparticule magnetice acoperite cu dextran și încărcate cu acid protocatehuic (MNP-Dex/PCA), cu scopul de a inhiba inflamația

vasculară prin reducerea expresiei citokinelor pro-inflamatoare și a adeziunii monocitelor la celulele endoteliale (CE) activate, în modele celulare *in vitro*.

2. Dezvoltarea și caracterizarea unor nanoparticule biomimetice încărcate cu SPM (Bio-LN/SPM) și testarea efectului acestora *in vitro* asupra fenotipului inflamator al CE, macrofagelor (Mφ) și celulelor musculare netede (CMN) implicate în patogeneza AS.
3. Evaluarea biodistribuției și a efectelor acute ale nanoparticulelor Bio-LN/SPM în modelul murin de AS (șoareci ApoE $^{-/-}$ hiperlipidemici), prin analizarea acumulării la nivelul aortei, a modificărilor în compoziția celulelor imune circulante și a profilului de citokine inflamatoare, la 24 de ore de la administrare.
4. Validarea eficacității preclinice a strategiei nanoterapeutice pro-rezolutive în AS, în modelul murin ApoE $^{-/-}$, prin demonstrarea efectului terapeutic al nanoparticulelor Bio-LN/SPM asupra leziunilor aterosclerotice aflate în două stadii de progresie a plăcii, cu accent pe reducerea inflamației vasculare și acumulării lipidice în aortă și rădăcina aortică.

B. Structura tezei

Teza de doctorat este structurată în două părți majore:

Partea I – Stadiul actual al cunoașterii cuprinde o analiză a literaturii de specialitate privind rolul inflamației în ateroscleroză (AS), mecanismele moleculare implicate în rezoluția acesteia și strategiile nanoterapeutice emergente, care pot influența pozitiv cursul bolii. Această parte este alcătuită din șase capitole, care oferă o bază teoretică solidă pentru dezvoltarea celor două direcții experimentale.

În ***capitolul 1*** este prezentată organizarea structurală și funcțională a sistemului cardiovascular, cu accent pe arhitectura peretelui arterial și pe rolul critic al celulelor endoteliale în menținerea homeostaziei vasculare. Sunt discutate dezechilibrele care pot perturba funcția endotelială și care contribuie la declanșarea patologiilor vasculare, precum AS.

Capitolul 2, „Inflamația în Ateroscleroză”, detaliază în mod sistematic etapele progresiei leziunilor aterosclerotice, pornind de la activarea endotelială și acumularea

LDL în spațiul subendotelial, până la formarea celulelor spumoase, a miezului necrotic și ruperea plăcii. Sunt evidențiate procesele inflamatoare care amplifică vulnerabilitatea plăcii și sunt discutate elementele celulare implicate.

Capitolul 3 este dedicat conceptului de „Rezoluție a inflamației" ca proces activ și cu mecanisme de reglare complexe, diferit de inhibarea clasică a inflamației. Este prezentat un cadru conceptual complet privind mediatorii specializați pro-rezoluție (SPM), precum lipoxinele, resolvinele, maresinele și protectinele, accentuând rolul lor în restabilirea homeostaziei tisulare. O sinteză extinsă a claselor, funcțiilor, mecanismelor de acțiune și receptorilor acestor mediatori a fost detaliată în cadrul acestui capitol, constituind baza teoretică pentru strategiile farmacologice pro-rezolutive propuse ulterior în partea experimentală a tezei.

Capitolul 4 evidențiază limitările terapiilor convenționale actuale, care vizează în principal scăderea nivelului lipidelor sau suprimarea răspunsului inflamator. Se argumentează că aceste strategii nu reușesc să prevină progresia leziunilor aterosclerotice și nu abordează cauza persistenței inflamației. Astfel, este justificată necesitatea unor intervenții terapeutice inovatoare, capabile nu doar să inhibe inflamația, ci și să activeze mecanismele fiziologice de rezoluție, promovând restaurarea homeostaziei vasculare.

Capitolul 5 introduce domeniul nanomedicinei, cu accent pe nanoterapia aplicată în bolile cardiovasculare. Sunt detaliate tipurile de nanoparticule utilizate în acest context, punându-se accent pe avantajele livrării direcționate și pe strategiile de funcționalizare menite să crească eficiența terapeutică. De asemenea, este prezentat conceptul de nanoparticule biomimetice, cu evidențierea potențialului acestora de a imita componente celulare naturale pentru a facilita recunoașterea specifică a țesuturilor inflamate și a îmbunătăți distribuția țintită a agenților terapeutici.

Capitolul 6 explorează aplicațiile directe ale SPM și ale analogilor lor sintetici în inflamația cronică și în AS. Sunt descrise studii preclinice și potențiale direcții de cercetare în care SPM sunt considerați terapii promițătoare, cu mecanisme complementare față de medicamentele anti-inflamatoare tradiționale.

Partea a II-a – Contribuții originale este dedicată studiilor experimentale realizate, împărțite în două direcții nanoterapeutice distincte:

Capitolul 1 descrie dezvoltarea, caracterizarea și evaluarea *in vitro* a nanoparticulelor magnetice acoperite cu dextran și încărcate cu acid protocatehuic (MNP-Dex/PCA). Studiul demonstrează eficiența acestor nanoparticule în reducerea expresiei citokinelor pro-inflamatoare în celulele endoteliale și în macrofagele de tip M1. De asemenea, MNP-Dex/PCA inhibă căile de semnalizare NF-κB și MAPK și reduc adeziunea monocitelor la endoteliul activat, susținând potențialul acestora în terapia inflamației vasculare.

Capitolul 2 este dedicat unui studiu amplu ce cuprinde secțiuni experimentale care vizează promovarea activă a rezoluției inflamației prin utilizarea de nanoparticule biomimetice încărcate cu mediatori specializați pro-rezoluție (Bio-LN/SPM).

- Secțiunea 1 prezintă procesul de sinteză și caracterizare fizico-chimică a nanoparticulelor biomimetice, inclusiv evaluarea compoziției, dimensiunii și potențialului zeta.
- Secțiunea 2 analizează efectele *in vitro* ale acestor nanoparticule asupra liniilor celulare relevante pentru AS (CE, Mϕ și SMC). S-a constatat o scădere semnificativă a expresiei markerilor inflamatori și promovarea unui fenotip anti-inflamator.
- Secțiunea 3 se concentrează pe testarea *in vivo* a Bio-LN/SPM în modelul murin $ApoE^{-/-}$, la 24 de ore post-injectare. Au fost evaluate distribuția nanoparticulelor și efectele acute asupra profilului imun.
- Secțiunea 4 investighează impactul terapeutic al Bio-LN/SPM asupra leziunilor aterosclerotice ale șoarecilor $ApoE^{-/-}$ aflate în două stadii diferite de progresie (4 săptămâni și 8 săptămâni de dietă bogată în grăsimi), evidențiind reducerea inflamației sistemice și locale și a acumulării de lipide, precum și inducerea unui fenotip pro-rezolutiv al macrofagelor de la nivelul plăcii aterosclerotice.

Astfel, structura tezei reflectă o abordare integrată și progresivă, de la înțelegerea detaliată a patologiei AS și a proceselor moleculare implicate în inflamație și rezoluție, până la dezvoltarea și validarea experimentală a unor soluții terapeutice inovatoare. Fiecare capitol contribuie logic și științific la consolidarea ipotezei de cercetare și la demonstrarea aplicabilității nanomedicinei în tratamentul personalizat al inflamației vasculare asociate AS.

C. Principalele rezultate și concluzii:

1. Obținerea nanoparticulelor magnetice MNP-Dex/PCA care pot fi folosite ca vehicule teranostice ce combină diagnosticul și terapia într-o singură platformă

- Au fost obținute nanoparticule stabile coloidal în care PCA a fost eficient adsorbit pe suprafața nanoparticulelor și menținut în formă activă.
- MNP-Dex/PCA au fost preluate eficient de celulele endoteliale și de macrofagele pro-inflamatoare M1, fără efecte citotoxice la concentrații < 100 μg/mL.
- Tratamentul cu MNP-Dex/PCA a determinat:
    - Inhibarea căilor de semnalizare inflamatorii NF-κB și MAPK cu reducerea expresiei IL-1β, TNF-α, IL-6, MCP-1, p38 și ERK1/2.
    - Diminuarea adeziunii monocitelor la endoteliul activat.

Aceste date confirmă potențialul acestor nanoparticule de a inhiba răspunsul inflamator vascular, deschizând posibilitatea utilizării lor în prevenția progresiei plăcii aterosclerotice.

2. Obținerea și validarea preclinică a nanoparticulelor biomimetice încărcate cu mediatori specializați pro-rezoluție într-un model murin de ateroscleroză

- S-au obținut nanoemulsii acoperite cu membrane celulare pentru a mima structura monocitelor circulante, având ca încărcătură activă SPM (Bio-LN/SPM).
- *In vitro,* Bio-LN/SPM:
    - Au redus expresia markerilor inflamatori (VCAM-1, MCP-1, NLRP3, IL-1β),
    - Au promovat un fenotip M2 pro-rezolutiv în macrofage (scăderea iNOS și creșterea capacității fagocitare),
    - Au diminuat adeziunea și transmigrarea monocitelor prin endoteliul activat.
- *In vivo* (șoareci $ApoE^{-/-}$ hrăniți cu dietă bogată în grăsimi):
    - Administrarea intravenoasă a Bio-LN/SPM a dus, după 24 de ore, la:
        - Reducerea monocitelor și neutrofilelor circulante,
        - Scăderea nivelurilor plasmatice de citokine (IFN-γ, CXCL10, IL-16, TIMP-1 și TNF-α) și chemokine (MCP-1 și C5a),
        - Acumulare selectivă la nivelul aortei.

- Administrarea repetată în două stadii diferite de progresie a plăcii aterosclerotice a demonstrat:
  - Scăderea inflamației sistemice și modularea populațiilor imune circulante,
  - Reducerea inflamației locale și inducerea unui fenotip pro-rezolutiv de tip M2 în macrofagele aortice, evidențiată prin creșterea expresiei markerilor CD206 și MerTK, concomitent cu scăderea nivelului iNOS,
  - Reducerea acumulării lipidice în leziuni.

Aceste rezultate confirmă faptul că Bio-LN/SPM nu doar inhibă inflamația, ci promovează rezoluția acesteia, reprogramând fenotipul imun și micromediul aortic.

D. Contribuțiile originale ale tezei

1. Dezvoltarea a două platforme nanoterapeutice cu mecanisme complementare, validate *in vitro* sau *in vivo*, pentru combaterea inflamației vasculare:

a) MNP-Dex/PCA – efect anti-inflamator prin inhibarea NF-κB și MAPK (Figura 1).

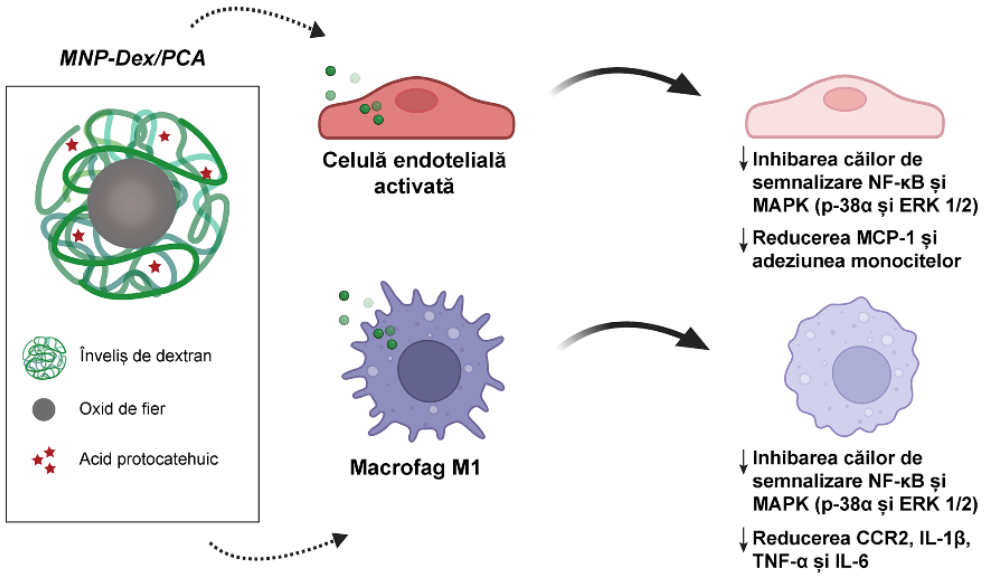

Figura 1. Strategia nanoterapeutică dezvoltată în cadrul primului studiu pentru combaterea inflamației vasculare asociate AS. Schema ilustrează mecanismul de acțiune al nanoparticulelor magnetice acoperite cu dextran și încărcate cu acid protocatehuic (MNP-Dex/PCA), care sunt internalizate de CE și MΦ de tip M1, determinând inhibarea căilor de semnalizare inflamatorii (NF-κB și MAPK p38α și ERK1/2) și limitarea adeziunii monocitelor.

b) Bio-LN/SPM – efect pro-rezolutiv, prin inducerea unui fenotip M2 în macrofage, scăderea merkerilor inflamatori și reducerea depozitelor lipidice în placa aterosclerotică (Figura 2).

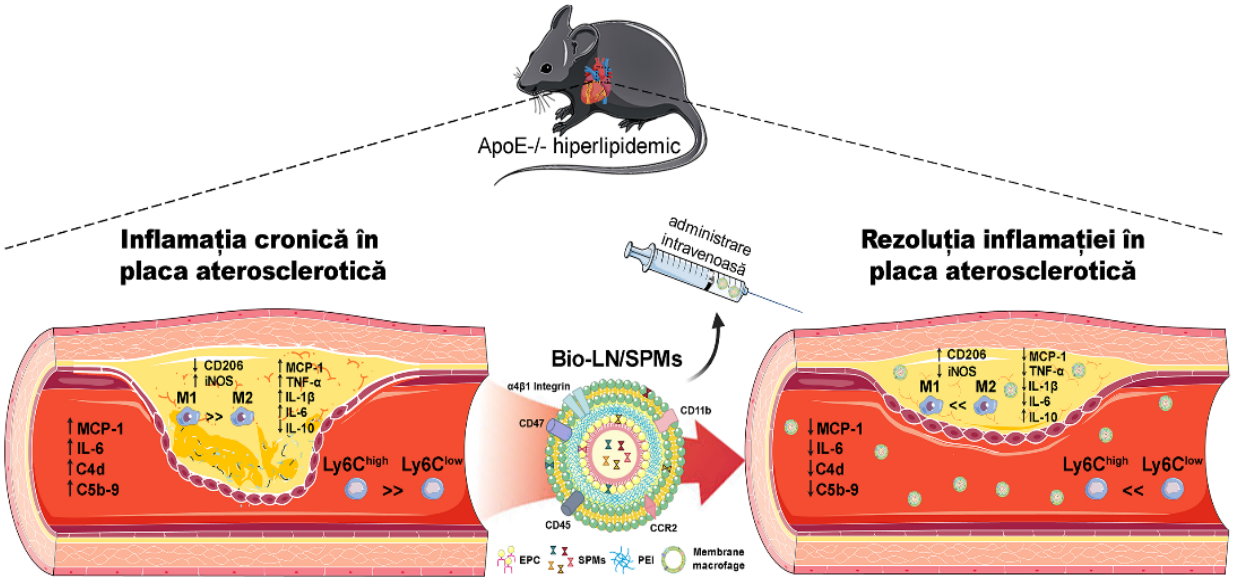

Figura 2. Reprezentare schematică a strategiei nanoterapeutice dezvoltate în cel de-al doilea studiu în vederea promovării rezoluției inflamației vasculare asociate AS. Este ilustrat efectul nanoparticulelor biomimetice încărcate cu mediatori specializați pro-rezoluție (Bio-LN/SPM) asupra CE, CMN vasculare și MΦ în modelul murin ApoE$^{-/-}$ hiperlipidemic. Tratamentul cu Bio-LN/SPM determină reducerea expresiei markerilor inflamatori circulanți și locali, inducerea unui fenotip reparator în MΦ și diminuarea acumulării lipidice în leziunile aterosclerotice.

2. Confirmarea rolului rezoluției inflamatorii în controlul AS și validarea SPM ca agenți terapeutici viabili în nanomedicina cardiovasculară.

E. Concluzii generale

Această teză aduce o contribuție semnificativă la înțelegerea și tratarea inflamației vasculare cronice în contextul AS, propunând două abordări nanoterapeutice complementare. În timp ce MNP-Dex/PCA inhibă căile inflamatorii pro-aterogene, Bio-LN/SPM promovează activ rezoluția inflamației, un proces esențial, dar ignorat până recent în tratamentele actuale. Prin aceste strategii, lucrarea demonstrează aplicabilitatea nanomedicinei în terapia cardiovasculară personalizată, deschizând noi direcții pentru intervenția precoce și țintită în AS.

A. Introducere și obiective

Bolile cardiovasculare (BCV) reprezintă principala cauză de mortalitate în România, responsabile pentru peste 55% dintre decesele anuale (Institutul Național de Sănătate Publică, 2024). În acest context, ateroscleroza (AS), o afecțiune cronică inflamatoare a peretelui vascular, joacă un rol central în dezvoltarea complicațiilor cardiovasculare acute, precum infarctul miocardic sau accidentul vascular cerebral. Deși terapiile convenționale, cum ar fi statinele și agenții antitrombotici, reduc incidența evenimentelor cardiovasculare, acestea nu reușesc să abordeze eficient inflamația vasculară persistentă, o componentă esențială a progresiei plăcii aterosclerotice (d'Aiello et al., 2024).

În mod particular, s-a demonstrat că eșecul rezoluției inflamației, proces fiziologic activ și coordonat, contribuie semnificativ la instabilitatea plăcilor și progresia bolii (Fredman, 2019). În acest context, mediatori specializați pro-rezoluție (SPM) precum resolvinele sau lipoxinele, reprezintă o clasă emergentă de molecule capabile să restabilească homeostazia vasculară prin inducerea activă a rezoluției inflamației. Cu toate acestea, utilizarea terapeutică a SPM este limitată de stabilitatea lor redusă în circulație și de biodisponibilitatea scăzută la locul leziunii aterosclerotice (Fredman & Serhan, 2024).

În paralel, compuși naturali precum acidul protocatehuic (PCA), cu rol anti-inflamator și antioxidant, au fost propuși ca adjuvanți în combaterea inflamației endoteliale și macrofagice. Totuși, eficacitatea lor terapeutică este limitată de biodisponibilitatea redusă și țintirea nespecifică (Cory et al., 2018). Nanotehnologia oferă o soluție inovatoare pentru aceste provocări, facilitând livrarea țintită și protejarea compușilor de interes în forme farmaceutice stabile (Ahmad et al., 2022).

Pornind de la aceste premise, **scopul principal al acestei teze de doctorat** a fost dezvoltarea și caracterizarea unor **platforme nanoterapeutice inovatoare** pentru combaterea inflamației vasculare în AS, având ca mecanisme complementare: (1) inducerea activă a rezoluției inflamației prin livrarea de SPM sau (2) inhibarea căilor inflamatoare pro-aterogene prin livrarea de PCA.

Au fost propuse și realizate următoarele **obiective specifice**:

1. Caracterizarea și testarea unor nanoparticule magnetice acoperite cu dextran și încărcate cu acid protocatehuic (MNP-Dex/PCA), cu scopul de a inhiba inflamația

vasculară prin reducerea expresiei citokinelor pro-inflamatoare și a adeziunii monocitelor la celulele endoteliale (CE) activate, în modele celulare *in vitro*.

2. Dezvoltarea și caracterizarea unor nanoparticule biomimetice încărcate cu SPM (Bio-LN/SPM) și testarea efectului acestora *in vitro* asupra fenotipului inflamator al CE, macrofagelor (Mφ) și celulelor musculare netede (CMN) implicate în patogeneza AS.
3. Evaluarea biodistribuției și a efectelor acute ale nanoparticulelor Bio-LN/SPM în modelul murin de AS (șoareci ApoE $^{-/-}$ hiperlipidemici), prin analizarea acumulării la nivelul aortei, a modificărilor în compoziția celulelor imune circulante și a profilului de citokine inflamatoare, la 24 de ore de la administrare.
4. Validarea eficacității preclinice a strategiei nanoterapeutice pro-rezolutive în AS, în modelul murin ApoE $^{-/-}$, prin demonstrarea efectului terapeutic al nanoparticulelor Bio-LN/SPM asupra leziunilor aterosclerotice aflate în două stadii de progresie a plăcii, cu accent pe reducerea inflamației vasculare și acumulării lipidice în aortă și rădăcina aortică.

B. Structura tezei

Teza de doctorat este structurată în două părți majore:

Partea I – Stadiul actual al cunoașterii cuprinde o analiză a literaturii de specialitate privind rolul inflamației în ateroscleroză (AS), mecanismele moleculare implicate în rezoluția acesteia și strategiile nanoterapeutice emergente, care pot influența pozitiv cursul bolii. Această parte este alcătuită din șase capitole, care oferă o bază teoretică solidă pentru dezvoltarea celor două direcții experimentale.

În ***capitolul 1*** este prezentată organizarea structurală și funcțională a sistemului cardiovascular, cu accent pe arhitectura peretelui arterial și pe rolul critic al celulelor endoteliale în menținerea homeostaziei vasculare. Sunt discutate dezechilibrele care pot perturba funcția endotelială și care contribuie la declanșarea patologiilor vasculare, precum AS.

Capitolul 2, „Inflamația în Ateroscleroză”, detaliază în mod sistematic etapele progresiei leziunilor aterosclerotice, pornind de la activarea endotelială și acumularea

LDL în spațiul subendotelial, până la formarea celulelor spumoase, a miezului necrotic și ruperea plăcii. Sunt evidențiate procesele inflamatoare care amplifică vulnerabilitatea plăcii și sunt discutate elementele celulare implicate.

Capitolul 3 este dedicat conceptului de „Rezoluție a inflamației" ca proces activ și cu mecanisme de reglare complexe, diferit de inhibarea clasică a inflamației. Este prezentat un cadru conceptual complet privind mediatorii specializați pro-rezoluție (SPM), precum lipoxinele, resolvinele, maresinele și protectinele, accentuând rolul lor în restabilirea homeostaziei tisulare. O sinteză extinsă a claselor, funcțiilor, mecanismelor de acțiune și receptorilor acestor mediatori a fost detaliată în cadrul acestui capitol, constituind baza teoretică pentru strategiile farmacologice pro-rezolutive propuse ulterior în partea experimentală a tezei.

Capitolul 4 evidențiază limitările terapiilor convenționale actuale, care vizează în principal scăderea nivelului lipidelor sau suprimarea răspunsului inflamator. Se argumentează că aceste strategii nu reușesc să prevină progresia leziunilor aterosclerotice și nu abordează cauza persistenței inflamației. Astfel, este justificată necesitatea unor intervenții terapeutice inovatoare, capabile nu doar să inhibe inflamația, ci și să activeze mecanismele fiziologice de rezoluție, promovând restaurarea homeostaziei vasculare.

Capitolul 5 introduce domeniul nanomedicinei, cu accent pe nanoterapia aplicată în bolile cardiovasculare. Sunt detaliate tipurile de nanoparticule utilizate în acest context, punându-se accent pe avantajele livrării direcționate și pe strategiile de funcționalizare menite să crească eficiența terapeutică. De asemenea, este prezentat conceptul de nanoparticule biomimetice, cu evidențierea potențialului acestora de a imita componente celulare naturale pentru a facilita recunoașterea specifică a țesuturilor inflamate și a îmbunătăți distribuția țintită a agenților terapeutici.

Capitolul 6 explorează aplicațiile directe ale SPM și ale analogilor lor sintetici în inflamația cronică și în AS. Sunt descrise studii preclinice și potențiale direcții de cercetare în care SPM sunt considerați terapii promițătoare, cu mecanisme complementare față de medicamentele anti-inflamatoare tradiționale.

Partea a II-a – Contribuții originale este dedicată studiilor experimentale realizate, împărțite în două direcții nanoterapeutice distincte:

Capitolul 1 descrie dezvoltarea, caracterizarea și evaluarea *in vitro* a nanoparticulelor magnetice acoperite cu dextran și încărcate cu acid protocatehuic (MNP-Dex/PCA). Studiul demonstrează eficiența acestor nanoparticule în reducerea expresiei citokinelor pro-inflamatoare în celulele endoteliale și în macrofagele de tip M1. De asemenea, MNP-Dex/PCA inhibă căile de semnalizare NF-κB și MAPK și reduc adeziunea monocitelor la endoteliul activat, susținând potențialul acestora în terapia inflamației vasculare.

Capitolul 2 este dedicat unui studiu amplu ce cuprinde secțiuni experimentale care vizează promovarea activă a rezoluției inflamației prin utilizarea de nanoparticule biomimetice încărcate cu mediatori specializați pro-rezoluție (Bio-LN/SPM).

- Secțiunea 1 prezintă procesul de sinteză și caracterizare fizico-chimică a nanoparticulelor biomimetice, inclusiv evaluarea compoziției, dimensiunii și potențialului zeta.
- Secțiunea 2 analizează efectele *in vitro* ale acestor nanoparticule asupra liniilor celulare relevante pentru AS (CE, Mϕ și SMC). S-a constatat o scădere semnificativă a expresiei markerilor inflamatori și promovarea unui fenotip anti-inflamator.
- Secțiunea 3 se concentrează pe testarea *in vivo* a Bio-LN/SPM în modelul murin $ApoE^{-/-}$, la 24 de ore post-injectare. Au fost evaluate distribuția nanoparticulelor și efectele acute asupra profilului imun.
- Secțiunea 4 investighează impactul terapeutic al Bio-LN/SPM asupra leziunilor aterosclerotice ale șoarecilor $ApoE^{-/-}$ aflate în două stadii diferite de progresie (4 săptămâni și 8 săptămâni de dietă bogată în grăsimi), evidențiind reducerea inflamației sistemice și locale și a acumulării de lipide, precum și inducerea unui fenotip pro-rezolutiv al macrofagelor de la nivelul plăcii aterosclerotice.

Astfel, structura tezei reflectă o abordare integrată și progresivă, de la înțelegerea detaliată a patologiei AS și a proceselor moleculare implicate în inflamație și rezoluție, până la dezvoltarea și validarea experimentală a unor soluții terapeutice inovatoare. Fiecare capitol contribuie logic și științific la consolidarea ipotezei de cercetare și la demonstrarea aplicabilității nanomedicinei în tratamentul personalizat al inflamației vasculare asociate AS.

C. Principalele rezultate și concluzii:

1. Obținerea nanoparticulelor magnetice MNP-Dex/PCA care pot fi folosite ca vehicule teranostice ce combină diagnosticul și terapia într-o singură platformă

- Au fost obținute nanoparticule stabile coloidal în care PCA a fost eficient adsorbit pe suprafața nanoparticulelor și menținut în formă activă.
- MNP-Dex/PCA au fost preluate eficient de celulele endoteliale și de macrofagele pro-inflamatoare M1, fără efecte citotoxice la concentrații < 100 μg/mL.
- Tratamentul cu MNP-Dex/PCA a determinat:
    - Inhibarea căilor de semnalizare inflamatorii NF-κB și MAPK cu reducerea expresiei IL-1β, TNF-α, IL-6, MCP-1, p38 și ERK1/2.
    - Diminuarea adeziunii monocitelor la endoteliul activat.

Aceste date confirmă potențialul acestor nanoparticule de a inhiba răspunsul inflamator vascular, deschizând posibilitatea utilizării lor în prevenția progresiei plăcii aterosclerotice.

2. Obținerea și validarea preclinică a nanoparticulelor biomimetice încărcate cu mediatori specializați pro-rezoluție într-un model murin de ateroscleroză

- S-au obținut nanoemulsii acoperite cu membrane celulare pentru a mima structura monocitelor circulante, având ca încărcătură activă SPM (Bio-LN/SPM).
- *In vitro,* Bio-LN/SPM:
    - Au redus expresia markerilor inflamatori (VCAM-1, MCP-1, NLRP3, IL-1β),
    - Au promovat un fenotip M2 pro-rezolutiv în macrofage (scăderea iNOS și creșterea capacității fagocitare),
    - Au diminuat adeziunea și transmigrarea monocitelor prin endoteliul activat.
- *In vivo* (șoareci $ApoE^{-/-}$ hrăniți cu dietă bogată în grăsimi):
    - Administrarea intravenoasă a Bio-LN/SPM a dus, după 24 de ore, la:
        - Reducerea monocitelor și neutrofilelor circulante,
        - Scăderea nivelurilor plasmatice de citokine (IFN-γ, CXCL10, IL-16, TIMP-1 și TNF-α) și chemokine (MCP-1 și C5a),
        - Acumulare selectivă la nivelul aortei.

- Administrarea repetată în două stadii diferite de progresie a plăcii aterosclerotice a demonstrat:
  - Scăderea inflamației sistemice și modularea populațiilor imune circulante,
  - Reducerea inflamației locale și inducerea unui fenotip pro-rezolutiv de tip M2 în macrofagele aortice, evidențiată prin creșterea expresiei markerilor CD206 și MerTK, concomitent cu scăderea nivelului iNOS,
  - Reducerea acumulării lipidice în leziuni.

Aceste rezultate confirmă faptul că Bio-LN/SPM nu doar inhibă inflamația, ci promovează rezoluția acesteia, reprogramând fenotipul imun și micromediul aortic.

D. Contribuțiile originale ale tezei

1. Dezvoltarea a două platforme nanoterapeutice cu mecanisme complementare, validate *in vitro* sau *in vivo*, pentru combaterea inflamației vasculare:

a) MNP-Dex/PCA – efect anti-inflamator prin inhibarea NF-κB și MAPK (Figura 1).

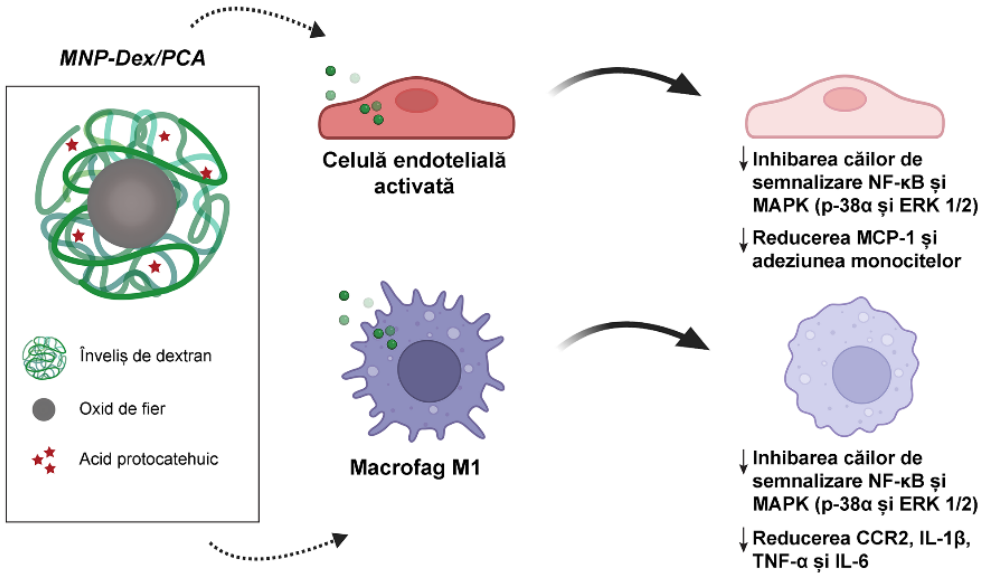

Figura 1. Strategia nanoterapeutică dezvoltată în cadrul primului studiu pentru combaterea inflamației vasculare asociate AS. Schema ilustrează mecanismul de acțiune al nanoparticulelor magnetice acoperite cu dextran și încărcate cu acid protocatehuic (MNP-Dex/PCA), care sunt internalizate de CE și MΦ de tip M1, determinând inhibarea căilor de semnalizare inflamatorii (NF-κB și MAPK p38α și ERK1/2) și limitarea adeziunii monocitelor.

b) Bio-LN/SPM – efect pro-rezolutiv, prin inducerea unui fenotip M2 în macrofage, scăderea merkerilor inflamatori și reducerea depozitelor lipidice în placa aterosclerotică (Figura 2).

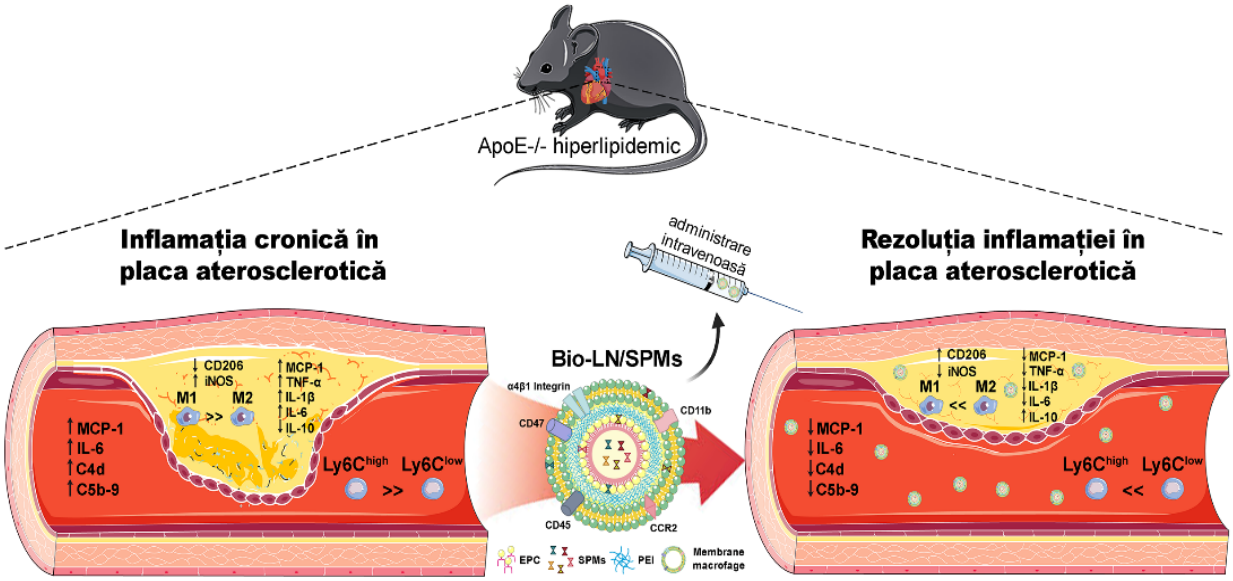

Figura 2. Reprezentare schematică a strategiei nanoterapeutice dezvoltate în cel de-al doilea studiu în vederea promovării rezoluției inflamației vasculare asociate AS. Este ilustrat efectul nanoparticulelor biomimetice încărcate cu mediatori specializați pro-rezoluție (Bio-LN/SPM) asupra CE, CMN vasculare și MΦ în modelul murin ApoE$^{-/-}$ hiperlipidemic. Tratamentul cu Bio-LN/SPM determină reducerea expresiei markerilor inflamatori circulanți și locali, inducerea unui fenotip reparator în MΦ și diminuarea acumulării lipidice în leziunile aterosclerotice.

2. Confirmarea rolului rezoluției inflamatorii în controlul AS și validarea SPM ca agenți terapeutici viabili în nanomedicina cardiovasculară.

E. Concluzii generale

Această teză aduce o contribuție semnificativă la înțelegerea și tratarea inflamației vasculare cronice în contextul AS, propunând două abordări nanoterapeutice complementare. În timp ce MNP-Dex/PCA inhibă căile inflamatorii pro-aterogene, Bio-LN/SPM promovează activ rezoluția inflamației, un proces esențial, dar ignorat până recent în tratamentele actuale. Prin aceste strategii, lucrarea demonstrează aplicabilitatea nanomedicinei în terapia cardiovasculară personalizată, deschizând noi direcții pentru intervenția precoce și țintită în AS.

I. Rezumat

Cuvinte cheie: miR-210, macrofage, fibroblaste, HEK, celule stem mezenchimale, inflamație, hipoxie.

Număr total de pagini – 211

Număr de figuri în Partea I – 22

Număr de tabele în Partea I – 1

Număr de figuri în Partea II – 74

Număr de tabele în Partea II –8

Referințe bibliografice – 244

Lucrări publicate în reviste indexate ISI în perioada stagiului de doctorat – 8 (1 autor principal)

Postere prezentate la manifestări științifice internaționale – 3 (autor principal)

Comunicări orale susținute la manifestări științifice internaționale – 1 (autor principal)

Burse obținute pe durata programului doctoral – 2

Participarea în proiecte de cercetare – 3

II. Introducere și Obiective

Acizii ribonucleici necodanți (ARNnc) reprezintă componente esențiale ale arhitecturii de reglare genomică, participând la controlul expresiei genice la nivel epigenetic, transcripțional și post-transcripțional (Esteller, 2011; Statello și colab., 2021). MicroARN-urile (miR) constituie o subclasă de ARNnc de mici dimensiuni (≈21–23 nucleotide), care reglează expresia genică post-transcripțional prin interacțiunea cu regiunea 3′UTR a ARN-urilor mesagere țintă, conducând la reprimarea translației și/sau degradarea transcriptului (Bartel, 2009; He și Hannon, 2004). Prin complementaritate parțială, un singur miR poate modula simultan expresia mai multor transcripți, contribuind la reglarea fină a programelor de expresie genică.

Hipoxia reprezintă o condiție de stres cu relevanță fiziopatologică majoră, prezentă în inflamația acută și cronică, ischemia tisulară și patologia cardiovasculară (Eltzschig și Carmeliet, 2011; Colgan și colab., 2020). Răspunsul celular la reducerea disponibilității oxigenului este coordonat de factorii inductibili de hipoxie (HIF), care modulează expresia genelor implicate în metabolismul energetic, angiogeneză și supraviețuire celulară (Semenza, 2012; Bakleh și Al Haj Zen, 2025). Stabilizarea HIF (Epstein și colab., 2001; Bruick și McKnight, 2001) declanșează un program transcripțional adaptativ caracterizat prin reprogramare metabolică și ajustarea funcției mitocondriale.

În acest context, miR-210 a fost identificat drept un reglator central al răspunsului celular la hipoxie, fiind direct controlat de HIF prin legarea la elemente de răspuns la hipoxie (HRE) conservate evolutiv (Chan și colab., 2012; Semenza, 2012). Funcțional, miR-210 modulează expresia genelor implicate în metabolismul mitocondrial, angiogeneză, repararea ADN și reglarea ciclului celular, contribuind la integrarea adaptării metabolice cu mecanismele de supraviețuire celulară în condiții de hipoxie (Chan și colab., 2009; Devlin și colab., 2011; He și colab., 2012). Organizarea genomică a locusului miR-210, localizat intronic în cadrul genei MIR210HG, sugerează o posibilă interdependență funcțională între miR-210 și contextul său genomic.

Majoritatea studiilor disponibile au utilizat modele de supraexpresie sau inhibiție tranzitorie, fără a evalua sistematic consecințele deleției genomice complete a locusului miR-210. Această limitare este relevantă în contextul organizării tridimensionale a genomului și al existenței domeniilor de asociere topologică (TAD), unde perturbarea unui locus genomic poate genera efecte transcriptomice extinse dincolo de secvența țintită (Dixon și colab., 2012; Nora și colab., 2012; Engreitz și colab., 2016).

Pe baza acestor considerente, în această teză ne-am propus să investigăm legătura dintre semnalizarea indusă de hipoxie și inflamație, evaluând în mod specific rolul locusului genomic al lui miR-210 în contexte inflamatorii relevante. Teza de doctorat pornește de la **ipoteza** conform căreia deleția genomică a locusului miR-210 determină perturbări ale rețelelor transcriptomice implicate în adaptarea celulară la hipoxie, prin mecanisme care ar putea reflecta atât absența miR-210 matur, cât și perturbarea contextului genomic local asociat locusului

MIR210HG.. În acest context, **scopul principal** al tezei a fost, pe de o parte, investigarea consecințelor funcționale și transcriptomice ale deleției lui miR-210 la nivel celular, iar pe de alta parte, investigarea consecințelor manipulării locusului miR-210 asupra stabilității genomice. Pentru atingerea acestui scop au fost stabilite următoarele **obiective specifice**: (i) caracterizarea șoarecilor transgenici (șoareci cu deleție constitutivă a miR-210 și șoareci cu supraexpresie inductibilă de miR-210); (ii) obținerea și validarea modelelor celulare cu deleție a locusului miR-210; (iii) evaluarea comparativă a răspunsului transcriptomic în celulele WT și miR-210 KO; (iv) identificarea genelor și căilor biologice modificate în urma deleției miR-210 sau a locusului MIR210HG; (v) analiza impactului deleției asupra efectelor funcționale ale pierderii locusului miR-210.

Noutatea acestei teze constă în analiza sistematică a efectelor deleției genomice complete a locusului miR-210 în condiții de normixie și hipoxie, într-un cadru experimental care permite distingerea între consecințele pierderii miR-ului matur și posibilele efecte asociate perturbării contextului genomic local (MIR210HG). Teza demonstrează că locusul miR-210 funcționează în interacțiune cu elementele genetice adiacente și subliniază importanța luării în considerare a localizării genomice și a caracteristicilor structurale ale fiecărui locus de ARN necodant în experimentele de pierdere a funcției realizate prin tehnologii de editare genomică.

În plus, evaluarea acestor efecte în celule primare relevante fiziologic (fibroblaste, macrofage, HEK), consolidează relevanța biologică a observațiilor și oferă un cadru interpretativ robust pentru modificările transcriptomice identificate. Prin integrarea modelelor murine transgenice, a celulelor primare și a liniilor celulare modificate genetic, teza propune o perspectivă unitară asupra rolului miR-210 la interfața dintre hipoxie și inflamație.

III. Structura tezei

Teza de doctorat este structurată în două părți majore:

Partea I – Stadiul actual al cunoașterii cuprinde o analiză a literaturii de specialitate privind rolul hipoxiei în reglarea răspunsului celular, interacțiunea funcțională dintre hipoxie și inflamație, precum și mecanismele de reglare post-transcripțională mediate de ARN-uri necodante, cu accent pe microARN-uri și, în mod particular, pe miR-210. Această parte este

structurată în trei capitole principale, care oferă cadrul teoretic necesar pentru dezvoltarea direcțiilor experimentale ale tezei. În **capitolul 1**, sunt prezentate mecanismele moleculare prin care hipoxia modulează răspunsul inflamator, cu accent pe rolul factorilor inductibili de hipoxie și pe interacțiunea acestora cu căile de semnalizare inflamatorii. Sunt analizate mai multe tipuri celulare implicate în inflamație, inclusiv macrofagele, fibroblastele și celulele stromale mezenchimale, precum și modul în care acestea răspund la stresul hipoxic (Davidson și colab., 2021; Bernardo și Fibbe, 2013). Capitolul evidențiază faptul că hipoxia și inflamația reprezintă procese biologice interdependente, care se influențează reciproc prin mecanisme moleculare și celulare comune. **Capitolul 2**, prezintă mecanismele generale de reglare post-transcripțională mediate de ARNnc, cu accent pe clasificarea acestora și pe rolul microARN-urilor în controlul expresiei genice. Sunt descrise procesele de biogeneză ale microARN-urilor (Bartel, 2004), mecanismele de acțiune și impactul acestora asupra rețelelor transcriptomice, subliniindu-se rolul lor în reglarea fină a proceselor biologice, inclusiv în contexte de stres celular precum hipoxia și inflamația. **Capitolul 3**, este dedicat analizei miR-210, considerat un reglator central al răspunsului la hipoxie. Sunt prezentate mecanismele de reglare a expresiei miR-210 de către HIF, organizarea genomică a locusului MIR210HG și funcțiile acestuia în controlul proceselor celulare, inclusiv metabolismul mitocondrial, angiogeneză, stabilitate genomică și reglarea răspunsului imun. Capitolul evidențiază rolul miR-210 ca element integrator al semnalizării hipoxice și inflamatorii. Prin integrarea acestor capitole, este conturat un cadru conceptual în care miR-210 este poziționat la interfața dintre hipoxie și inflamație, constituind un potențial reglator cheie al adaptării celulare la stres.

Partea a II-a – Contribuții originale este dedicată studiilor experimentale realizate pentru investigarea rolului miR-210 și al locusului său genomic în reglarea răspunsului celular la hipoxie și inflamație, utilizând modele murine transgenice și multiple tipuri celulare relevante fiziologic. **Capitolul 1** este dedicat caracterizării modelelor murine transgenice utilizate în studii. Șoarecii au fost obținuți de la colaboratorii noștri, modelul miR-210 OE de la Prof. Dr. Fabio Martelli (Policlinico San Donato, Italia), iar modelul miR-210 KO de la Prof. Dr. Mircea Ivan (Indiana University, SUA). Sunt prezentate strategiile de generare a modelelor animale (deleția constitutivă, respectiv supraexpresia inductibilă a miR-210) și metodele caracterizare și validarea moleculară a celor două linii. Acest capitol stabilește cadrul experimental necesar

pentru investigarea consecințelor pierderii sau supraexpresiei miR-210 *in vivo* și *ex vivo*. **Capitolul 2** analizează rolul miR-210 în fibroblaste, cu accent pe modificările transcriptomice și funcționale asociate deleției acestuia. Sunt investigate răspunsurile celulare în condiții de normoxie și hipoxie, evidențiindu-se impactul asupra proceselor de proliferare și adaptare metabolică. **Capitolul 3** analizează comportamentul celulelor stromale mezenchimale în condiții de inflamație și hipoxie, cu accent pe supraviețuire, proliferare și activarea programelor imunomodulatoare. Sunt evaluate efectele stimulilor proinflamatori asupra viabilității celulare, expresiei genelor implicate în funcția imunomodulatoare și producției de oxid nitric. De asemenea, este investigat impactul asocierii dintre inflamație și hipoxie asupra supraviețuirii MSC, evidențiindu-se faptul că acest microambient afectează negativ homeostazia și funcția acestor celule. **Capitolul 4** investighează rolul miR-210 în macrofage, cu accent pe polarizarea acestora și pe reglarea răspunsului inflamator. Sunt analizate macrofagele miR-210 KO, evidențiindu-se alterarea polarizării anti-inflamatorii și favorizarea unui fenotip pro-inflamator în absența miR-210. **Capitolul 5** este dedicat studiului rolului locusului genomic miR-210 în linii celulare umane (HEK293T) modificate prin editare genomică. Sunt analizate consecințele deleției asupra expresiei genice și asupra proceselor celulare, inclusiv proliferare, organizarea fusului mitotic și stabilitatea genomică. Rezultatele sugerează că efectele observate nu sunt limitate la absența miR-210 matur, ci reflectă și perturbarea contextului genomic al locusului MIR210HG.

Astfel, structura acestei părți reflectă o abordare progresivă, de la validarea modelelor experimentale până la analiza funcțională și transcriptomică în diferite tipuri celulare. Integrarea rezultatelor obținute evidențiază faptul că miR-210 acționează ca un reglator al adaptării celulare la hipoxie și al răspunsului inflamator, iar efectele deleției sale nu pot fi atribuite exclusiv pierderii miR-ului matur, ci includ și consecințe asociate perturbării contextului genomic al locusului MIR210HG.

IV. Principalele rezultate

Capitolul 1. Caracterizarea modelelor murine transgenice pentru studiul miR-210

Un prim rezultat important al tezei a fost reprezentat de validarea și caracterizarea celor două modele murine transgenice utilizate pentru studiul funcției miR-210: modelul cu deleție constitutivă a miR-210 (miR-210 KO) și modelul cu supraexpresie inductibilă a miR-210 (miR-210 OE). În cazul modelului miR-210 KO, genotiparea a permis diferențierea clară a animalelor WT, heterozigote și homozigote, pe baza produșilor de PCR obținuți; iar absența expresiei miR-210 a fost confirmată prin RT-qPCR atât în ventriculul stâng, cât și în macrofagele derivate din măduva osoasă.

În paralel, modelul miR-210 OE a permis inducerea controlată a expresiei miR-210 prin sistemul Tet-On, cu integrarea transgenei în locusul ROSA26. Administrarea de doxiciclină a determinat creșterea semnificativă a expresiei miR-210 în inimă și mușchi scheletic, într-o manieră dependentă de doză, confirmând funcționalitatea modelului *in vivo*. Totuși, studiile efectuate pe celule izolate de la aceste animale au evidențiat caracterul tranzitoriu al supraexpresiei și imposibilitatea reactivării eficiente a sistemului Tet-On în cultură, sugerând existența unor constrângeri specifice mediului *in vivo*. În ansamblu, acest capitol a furnizat modelele experimentale și metodologia necesare pentru evaluarea rolului miR-210 în diferite tipuri celulare și contexte biologice.

Capitolul 2. Modificări transcriptomice și funcționale în fibroblaste cu deleție de miR-210

În acest capitol a fost studiat impactul deleției miR-210 asupra metabolismului și funcției fibroblastelor, utilizând fibroblaste dermice murine izolate de la șoarecii transgenici. Validarea deleției a demonstrat absența completă a expresiei miR-210 în fibroblastele KO, atât în normoxie, cât și în hipoxie, în timp ce fibroblastele WT au prezentat inducție pronunțată a miR-210 în condiții hipoxice. Analiza transcriptomică comparativă a fibroblastelelor miR-210 KO a evidențiat modificări semnificative în căile biologice asociate fosforilării oxidative, glicolizei, metabolismului acizilor grași, semnalizării mTORC1 și răspunsului la hipoxie, susținând rolul miR-210 în integrarea adaptării metabolice la stresul hipoxic.

Un rezultat notabil a fost identificarea unor modificări de expresie la nivelul genelor situate în proximitatea genomică a locusului miR-210, inclusiv Rassf7, Rnh1, Taldo1 și Cd151, ceea ce sugerează că deleția acestui locus poate afecta nu doar funcția microARN-ului matur, ci și reglarea transcripțională locală în cadrul domeniului genomic care îl conține. Din punct de vedere funcțional, fibroblastele miR-210 KO au prezentat o reducere semnificativă a capacității respiratorii maxime și a rezervei respiratorii mitocondriale (Figura 1a), precum și o creștere a ROS mitocondriale în hipoxie. În plus, analiza ciclului celular a evidențiat o redistribuire a celulelor între fazele ciclului celular, caracterizată prin acumularea în faza S și reducerea proporției de celule aflate în faza G0/G1, sugerând o dereglare a tranziției G1/S și o perturbare a progresiei ciclului celular, asociată cu o diminuare a ratei de proliferare celulară (Figura 1b). Aceste date demonstrează că miR-210 contribuie la menținerea homeostaziei mitocondriale, a echilibrului redox și a progresiei corecte a ciclului celular în fibroblaste, în special în condiții de stres hipoxic.

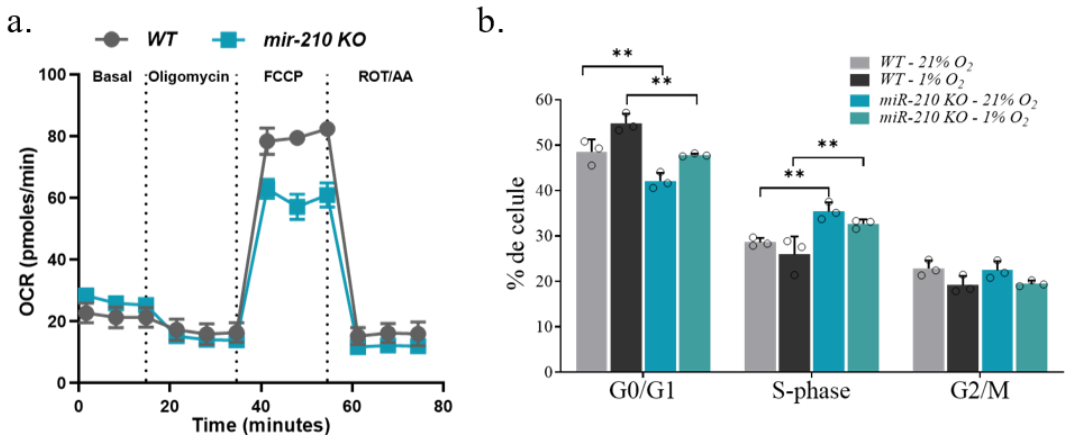

Figura 1. *Profilul OCR în fibroblastele WT și miR-210 KO și analiza ciclului celular în fibroblaste WT și miR-210 KO în normoxie (21% O_2) și hipoxie (1% O_2). (a) Reprezentarea temporală a dinamicii OCR măsurată prin testul Seahorse Mito Stress în condiții bazale și după adăugarea inhibitorilor. (b) Reprezentarea cantitativă a procentului celulelor aflate în fazele G0/G1, S și G2/M. Datele sunt exprimate ca medie ± SD. Analiza statistică: two-way ANOVA; **p < 0.01. (Figură adaptată după Preda și colab., 2025)*

Capitolul 3. Comportamentul celulelor stromale mezenchimale în inflamație și hipoxie

Acest capitol a urmărit modul în care microambientul inflamator și hipoxic influențează fenotipul și supraviețuirea celulelor stromale mezenchimale (MSC), având în vedere rolul lor central în reglarea inflamației și regenerarea tisulară. Rezultatele au arătat că stimularea inflamatorie activează programele imunomodulatoare ale MSC, evidențiate prin creșterea expresiei genelor IDO1, NOS2 și COX2. În același timp, TNF-α a inhibat proliferarea într-o manieră dependentă de doză, iar asocierea TNF-α și IFN-γ a amplificat acest efect, inducând modificări morfologice compatibile cu stresul celular și moartea celulară.

Un rezultat important a fost demonstrarea faptului că activarea inflamatorie a MSC este însoțită de o creștere semnificativă a producției de oxid nitric, iar inhibarea NOS2 a ameliorat parțial viabilitatea celulară, sugerând implicarea excesului de NO în citotoxicitatea observată. În condiții de hipoxie moderată, MSC și-au menținut inițial viabilitatea, însă asocierea hipoxiei cu stimulii inflamatori a determinat o reducere accentuată a supraviețuirii celulare. În ansamblu, datele obținute arată că interacțiunea dintre inflamație și hipoxie compromite funcția și viabilitatea MSC, prin activarea excesivă a căilor dependente de NOS2 și prin perturbarea homeostaziei redox. Aceste rezultate subliniază importanța optimizării condițiilor de precondiționare și cultură pentru utilizarea terapeutică a MSC în contexte inflamatorii și hipoxice.

Capitolul 4. Rolul miR-210 în modularea funcției macrofagelor în inflamație

În acest capitol a fost analizat rolul miR-210 în reglarea funcției macrofagelor derivate din măduva osoasă, cu accent pe polarizarea funcțională, profilul metabolic și răspunsul inflamator. Monocitele izolate din măduva osoasă au fost diferențiate în macrofage M0 și polarizate ulterior către fenotipul M2. Analizele efectuate au arătat că macrofagele provenite de la șoarecii miR-210 KO prezintă un profil inflamator accentuat în starea bazală și o tranziție deficitară către fenotipul M2. Analiza transcriptomică a indicat modificări semnificative ale expresiei genice atât în macrofagele M0, cât și în cele M2, iar analizele bioinformatice au evidențiat activarea căilor implicate în răspunsul la stres oxidativ, hipoxie și inflamație, concomitent cu reducerea expresiei genelor asociate răspunsului dependent de interferon și semnalizării IL-6/STAT3 (Figura 2 a,b).

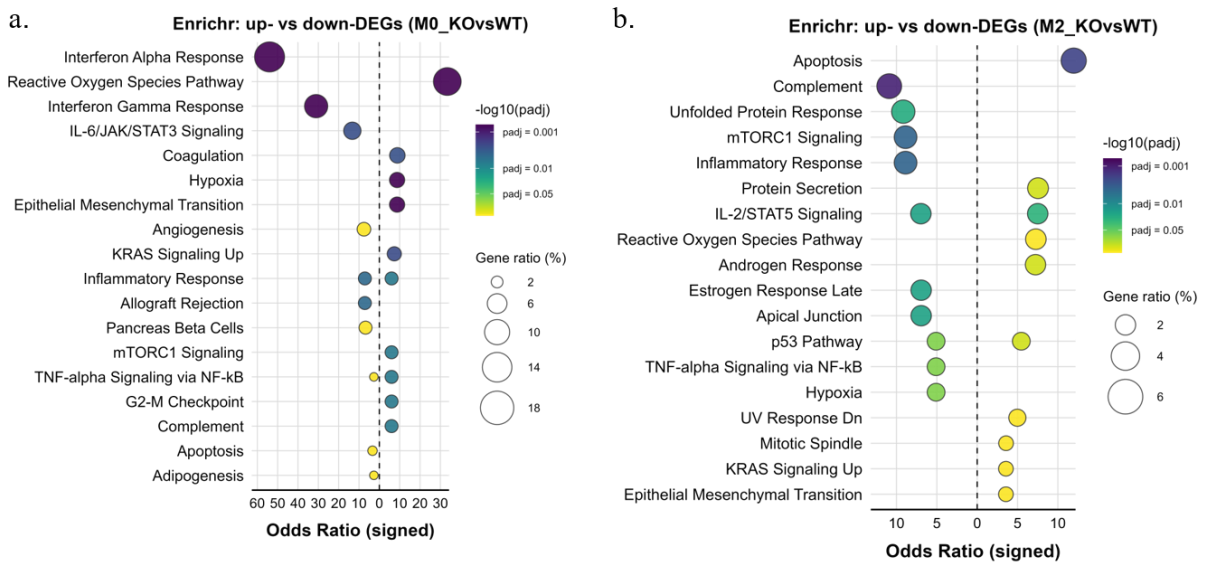

Figura 2. *Efectele deleției miR-210 în macrofagele M0 și M2. Reprezentări dot-plot obținute cu platforma Enrichr, care evidențiază căile biologice semnificativ îmbogățite în rândul genelor diferențial exprimate (DEG) între macrofagele provenite de la șoarecii miR-210 KO și cele WT: (a) în macrofagele de tip M0 și (b) în macrofagele de tip M2 (adaptat după Neculachi și colab., 2025).*

Aceste rezultate au fost confirmate funcțional prin creșterea secreției de IL-6, TNF-α și IL-1β în macrofagele M0 miR-210 KO și prin acumularea precursorului pro-IL-1β, indicând o activare inflamatorie intrinsecă în absența acestui microARN. În condiții de polarizare M2, macrofagele KO au prezentat o reprogramare incompletă, cu reducerea markerilor M2, activarea căilor proapoptotice și susceptibilitate crescută la apoptoză după stimularea cu TNF-α. De asemenea, a fost evidențiată creșterea nivelurilor proteinelor p53, TGF-β și MMP-9, sugerând activarea unor programe asociate stresului celular și remodelării tisulare. Analiza metabolică a arătat că macrofagele M0 KO au o activitate glicolitică bazală redusă, iar testele funcționale au demonstrat o activitate fagocitară și eferocitară crescută (Figura 3 a,b). În ansamblu, rezultatele demonstrează că miR-210 acționează ca un regulator integrator al metabolismului și inflamației în macrofage, contribuind la menținerea echilibrului dintre activarea inflamatorie, supraviețuire și polarizarea alternativă.

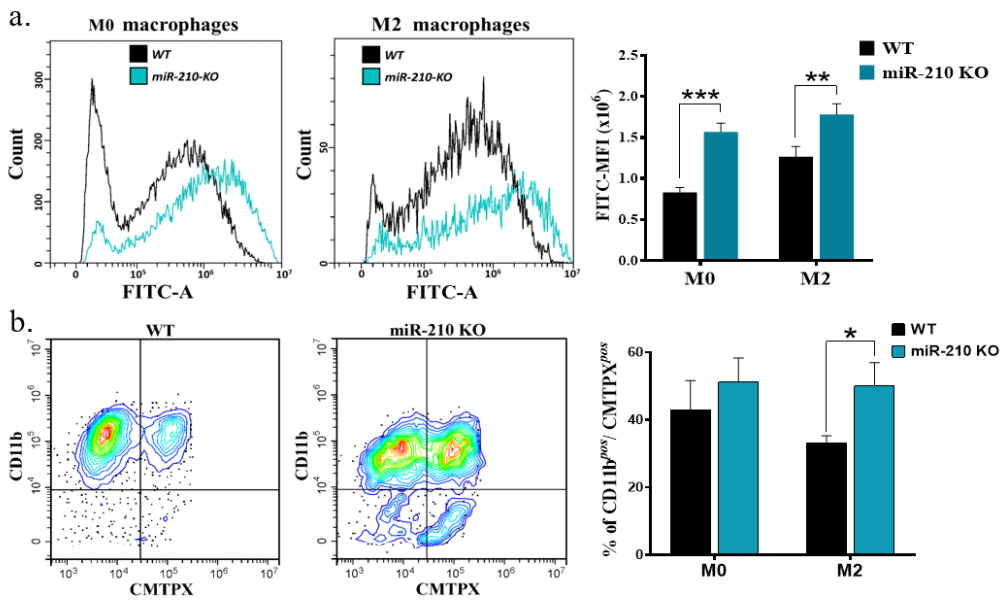

Figura 3. *Caracterizarea funcțională a macrofagelor miR-210 KO. (a) Capacitatea fagocitară a macrofagelor M0 și M2 (citometrie în flux), cuantificată ca FITC-MFI (n = 6/condiție). (b) Capacitatea de eferocitoză a macrofagelor WT și miR-210 KO, cuantificată ca procent de celule CD11b⁺CMTPX⁺ în condițiile M0 și M2 (n=3/condiție). Datele sunt exprimate ca medie ± SEM. Analiza statistică: two-way ANOVA, **p < 0,01, ***p < 0,001 (adaptat după Neculachi și colab., 2025).*

Capitolul 5. Impactul deleției miR-210 asupra transcriptomului în celulele HEK293T

Pentru evaluarea rolului locusului miR-210 într-un context genomic uman, a fost dezvoltat un model experimental bazat pe celulele HEK293T, în care au fost generate două tipuri de clone knockout: clone cu deleția secvenței pre-miR-210 și clone cu deleția extinsă a locusului MIR210HG. Validarea moleculară a confirmat absența expresiei miR-210 și a transcriptului gazdă MIR210HG în hipoxie. Analiza transcriptomică prin RNA-seq a evidențiat modificări consistente ale expresiei genice în celulele knockout, afectând în special căi implicate în adaptarea la hipoxie, reglarea ciclului celular, semnalizarea mTORC1, răspunsul la stres celular, activarea NF-κB și răspunsul la stres proteotoxic. Aceste rezultate arată că deleția locusului miR-210 perturbă programele de adaptare celulară la hipoxie și afectează mecanismele de control al proliferării.

Un rezultat notabil al acestui capitol a fost demonstrarea existenței unui efect local, de tip cis, asupra expresiei genelor situate în vecinătatea locusului MIR210HG. Gene localizate într-un interval de aproximativ 400–500 kb în jurul locusului au prezentat modificări de expresie, iar analiza interacțiunilor cromatiniene, utilizând date Hi-C publice, a sugerat integrarea regiunii într-un domeniu topologic asociat (TAD). Aceste date susțin ipoteza că deleția locusului miR-210 poate altera arhitectura locală a cromatinei și interacțiunile cis-reglatoare din regiune. Testele funcționale au arătat că deleția locusului miR-210 reduce capacitatea proliferativă și afectează respirația mitocondrială, iar analiza ciclului celular a indicat o întârziere a tranziției G1/S în hipoxie.

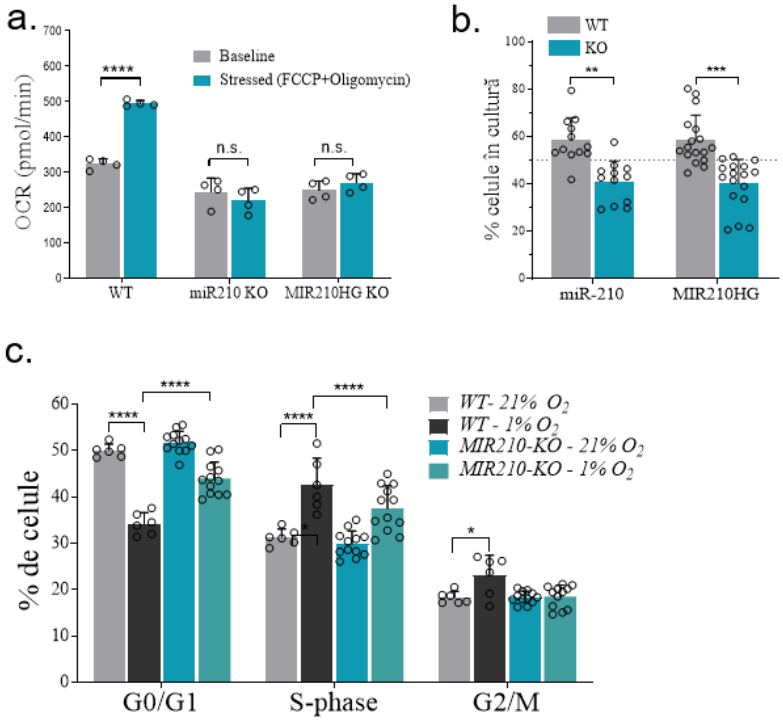

Figura 4. *Consecințele funcționale ale deleției locusului miR-210 în celulele HEK293T. (a) Modificările OCR în clonele HEK, măsurate în condiții bazale și de stres. (b) Teste de proliferare competitivă între clonele WT marcate cu GFP și miR210-KO sau MIR210HG-KO marcate cu dTomato, analizate după 3 zile de co-cultură. (c) Analiza distribuției ciclului celular în celulele HEK cultivate în condiții de normoxie și hipoxie. Analiza statistică a fost realizată utilizând testul two-way ANOVA, iar semnificația statistică este reprezentată astfel: *p < 0.05, **p < 0.01, ***p < 0.001, ****p < 0.0001, (Figură adaptată după Preda, M.B.,2025).*

În ansamblu, aceste rezultate demonstrează că fenotipul asociat deleției locusului miR-210 nu poate fi explicat exclusiv prin pierderea miR-210 matur, ci reflectă și perturbarea unei unități genomice integrate, care include transcriptul gazdă MIR210HG și elemente locale de reglare.

V. Concluzii generale

Rezultatele acestei teze arată faptul că miR-210 funcționează ca un reglator integrator la interfața dintre hipoxie și inflamație. Atât în fibroblaste, cât și în celulele umane HEK293T, deleția miR-210 / a locusului său determină o dereglare comună a adaptării celulare la hipoxie: perturbarea programelor metabolice și a funcției mitocondriale (reducerea capacității respiratorii), alterarea progresiei ciclului celular la nivelul tranziției G1/S și afectarea programelor transcripționale de răspuns la hipoxie. În plus, în ambele modele deleția produce un efect local, de tip cis: sunt modificate gene învecinate locusului (Rassf7, Rnh1, Taldo1, Cd151), integrate într-un domeniu topologic asociat (TAD) — ceea ce arată că locusul miR-210/MIR210HG se comportă ca o unitate genomică integrată, fenotipul deleției neputând fi explicat exclusiv prin pierderea microARN-ului matur. În macrofage, miR-210 menține echilibrul dintre activarea inflamatorie și polarizarea reparatorie: absența sa determină un fenotip proinflamator bazal (IL-6, TNF-α, IL-1β) și o reprogramare M2 incompletă, însoțită de activarea programelor de stres celular (p53, TGF-β, MMP-9), poziționând miR-210 ca reglator integrator al metabolismului și al răspunsului inflamator. În ansamblu, consecințele funcționale ale pierderii miR-210 reflectă atât absența miR-ului matur, cât și perturbarea arhitecturii cromatiniene locale.

VI. Contribuțiile originale ale tezei

1. Caracterizarea și validarea moleculară a două modele murine transgenice complementare pentru studiul funcțional al miR-210 — deleție constitutivă (KO) și supraexpresie inductibilă Tet-On/ROSA26 (OE), prin genotipare și RT-qPCR în țesuturi și în celule primare derivate.

2. Demonstrarea inducției dependente de doză a miR-210 *in vivo* în modelul OE și a caracterului tranzitoriu al supraexpresiei în cultură.

3. Identificarea, în fibroblastele cu deleție de miR-210, a unei semnături transcriptomice de dereglare metabolică (fosforilare oxidativă, glicoliză, metabolismul acizilor grași, semnalizare mTORC1 și răspuns la hipoxie).

4. Demonstrarea reducerii capacității respiratorii maxime și a rezervei respiratorii mitocondriale, însoțită de creșterea ROS mitocondriale în hipoxie, în fibroblastele miR-210 KO.

5. Demonstrarea perturbării ciclului celular în fibroblastele KO (acumulare în faza S, reducerea fracției G0/G1 și dereglarea tranziției G1/S), cu diminuarea ratei de proliferare.

6. Identificarea unui efect local al deleției asupra genelor învecinate locusului miR-210 (Rassf7, Rnh1, Taldo1, Cd151), indicând perturbarea reglării transcripționale din domeniul genomic care îl conține.

7. Demonstrarea unui fenotip proinflamator bazal accentuat în macrofagele M0 miR-210 KO (creșterea secreției de IL-6, TNF-α și IL-1β și acumularea precursorului pro-IL-1β).

8. Demonstrarea reprogramării deficitare către fenotipul M2 a macrofagelor KO (reducerea markerilor M2, susceptibilitate crescută la apoptoză după TNF-α și creșterea p53, TGF-β și MMP-9).

9. Demonstrarea unei activități glicolitice bazale reduse și a unei capacități fagocitare și eferocitare crescute la macrofagele miR-210 KO, poziționând miR-210 ca reglator integrator al metabolismului și inflamației.

10. Dezvoltarea unui model celular uman (HEK293T) cu deleția fie a secvenței pre-miR-210, fie a întregului locus MIR210HG, prin editare genomică.

11. Demonstrarea, prin RNA-seq, a perturbării programelor de adaptare la hipoxie, reglare a ciclului celular, semnalizare mTORC1 și NF-κB și răspuns la stres proteotoxic în clonele HEK293T KO.

12. Identificarea unui efect cis asupra expresiei genelor situate la ~400–500 kb de locus și, prin integrarea datelor Hi-C, plasarea regiunii într-un domeniu topologic asociat (TAD),

susținând conceptul că locusul miR-210/MIR210HG funcționează ca o unitate genomică integrată.

CUPRINS

LISTA ABREVIERILOR 6

INTRODUCERE ȘI OBIECTIVE 8

PARTEA I- STADIUL ACTUAL AL CUNOȘTINȚELOR PRIVIND INFLAMAȚIA ȘI UTILIZAREA POLIFENOLILOR ÎNCORPORAȚI ÎN NANOPARTICULE ÎN TERAPIA ANTI-INFLAMATORIE 10

CAPITOLUL 1- INFLAMAȚIA: MECANISME IMPLICATE ȘI TERAPIILE ACTUALE 10

1.1. Inflamaţia și bolile asociate 10

1.2. Cascada inflamatorie 11

1.3. Căi de semnalizare în inflamaţie 13

1.4. Clase de proteine implicate în procesele inflamatorii 17

1.4.1. Citokine 17

1.4.2. Chemokine 21

1.4.3. Molecule de adeziune 24

1.5. Inflamaţia indusă de lipopolizaharid (LPS) 27

1.6. Abordări terapeutice actuale anti-inflamatoare 29

CAPITOLUL 2-ABORDĂRI ALTERNATIVE BAZATE PE POLIFENOLI ÎNCORPORAŢI ÎN NANOTRANSPORTORI ÎN TERAPIA INFLAMAŢIEI 33

2.1. Polifenoli-aspecte generale 33

2.2. Proprietăţile anti-oxidante și anti-inflamatorii ale polifenolilor 35

2.3. Modularea microARN necodante 35

2.4. Modularea microbiotei intestinale 36

2.5. Limitări în utilizarea polifenolilor 37

2.6. Aplicaţii pe bază de nanoparticule (NP) ale polifenolilor anti-inflamatori 38

2.6.1. Activități anti-inflamatorii ale NP anorganice încărcate cu polifenoli 39

2.6.2. Activități anti-inflamatorii ale NP organice încărcate cu polifenoli 39

2.6.2.1. Nanoparticule polimerice 39

2.6.2.2. Nanoparticule de ciclodextrină 41

2.6.2.3. Nanoparticule lipidice 42

2.6.2.4. Nanoparticule pe bază de proteine 45

2.6.3. Acumularea pasivă și ţintirea activă a nanoparticulelor la situsuri inflamatorii 46

2.6.4. Ţintirea specifică a diferitelor tipuri celulare cu nanoparticule încărcate cu polifenoli 47

2.6.5. Studii clinice 50
2.6.6. Concluzii 53
PARTEA a II a- CONTRIBUȚII ORIGINALE 54
CAPITOLUL 3- PREPARAREA ȘI CARACTERIZAREA *IN VITRO* A NANOEMULSIILOR LIPIDICE INCĂRCATE CU FLAVONOIDELE NARINGENINĂ ȘI HESPERETINĂ 54
3.1. Introducere și obiective 54
3.2. Materiale si metode 56
3.2.1. Reactivi 56
3.2.2. Prepararea nanoemulsiilor lipidice (LN) încărcate cu flavonoide 57
3.2.3. Prepararea nanoemulsiilor încărcate cu flavonoide și ţintite la VCAM-1 58
3.2.4. Caracterizarea nanoemulsiilor incărcate cu flavonoide 59
3.2.4.1. Dimensiunea nanoparticulelor 59
3.2.4.2 Potenţialul zeta al nanoparticulelor 60
3.2.4.3. Determinarea peptidei cuplate pe suprafaţa LN 60
3.2.4.4. Determinarea conţinutului de flavonoid încapsulat în nanoemulsii lipidice 61
3.2.4.5. Eliberarea in vitro a flavonoidelor încorporate în nanoemulsii 62
3.2.4.6. Studii de stabilitate a nanoemulsiilor lipidice incărcate cu flavonoide 63
3.2.5. Culturi celulare 63
3.2.6. Test de viabilitate celulară 63
3.2.7. Preluarea nanoemulsiilor lipidice de către celulele endoteliale umane, linia EA.hy926 64
3.2.8. Testul de adeziune a monocitelor la celulele endoteliale 64
3.2.9. Testul de transmigrare a monocitelor 65
3.2.10. Imuno-blot 66
3.2.11. Prepararea extractelor nucleare și citosolice 67
3.2.12. Real Time PCR 67
3.2.13. Testul de hemocompatibilitate 68
3.2.14. Analiza statistică 68
3.3. Rezultate 68
3.3.1. Prepararea și caracterizarea nanoemulsiilor lipidice: dimensiune și potenţial zeta 68
3.3.2. Eficienţa de încapsulare 72
3.3.3. Stabilitatea nanoemulsiilor lipidice încărcate cu flavonoide 72
3.3.4. Eliberarea in vitro a flavonoidelor din nanoemulsii 73
3.3.5. Citotoxicitatea nanoemulsiilor încărcate cu flavonoide asupra celulelor endoteliale (CE) umane, linia EA.hy926 75

3.3.6. Internalizarea nanoemulsiilor lipidice de către CE activate cu TNF-α 76

3.3.7. Rolul funcţional al nanoparticulelor încărcate cu flavonoid în reducerea adeziunii și transmigrării monocitelor la/printre CE activate cu TNF-α 79

3.3.8. Reducerea expresiei MCP-1 în CE activate cu TNF-α de către nanoemulsiile lipidice încărcate cu flavonoide 81

3.3.9. Reducerea translocării nucleare a NF-kB în CE activate cu TNF-α de către nanoemulsiile lipidice încărcate cu flavonoide 82

3.3.10. Hemocompatibilitatea nanoemulsiilor lipidice încărcate cu flavonoide 83

3.4. Discuţii 84

3.5. Concluzii 87

CAPITOLUL 4-BIODISTRIBUŢIA NANOEMULSIILOR LIPIDICE INCĂRCATE CU NARINGENINĂ DETERMINATĂ CU AJUTORUL TRASORULUI INDOCYANINE GREEN (ICG) 88

4.1. Introducere și obiective 88

4.2.Materiale si metode 90

4.2.1. Reactivi 90

4.2.2. Prepararea nanoemulsiilor încărcate cu naringenină conţinând ICG 91

4.2.3. Prepararea nanoemulsiilor încărcate cu naringenină conţinând rodamină 92

4.2.4. Prepararea nanoemulsiilor ţintite încărcate cu naringenină și ICG 92

4.2.5. Caracterizarea fizico-chimică a nanoemulsiilor 92

4.2.5.1. Dimensiunea nanoparticulelor 92

4.2.5.2. Potenţialul zeta al nanoparticulelor 92

4.2.5.3. Determinarea conţinutului de naringenină încorporată în nanoemulsii lipidice 92

4.2.6. Evaluarea stabilităţii nanoemulsiilor cu naringenină și ICG în prezenţa serului in vitro 93

4.2.7. Imagistică de fluorescenţă 93

4.2.8. Studii pe animale- Modelul experimental de inflamaţie murină indusă de LPS 93

4.2.9. Dozarea naringeninei în omogenate tisulare prin UHPLC 94

4.2.10. Analiza statistică 95

4.3. Rezultate 95

4.3.1. Caracterizarea fizico-chimică a nanoparticulelor cu narigenină și ICG 95

4.3.2. Stabilitatea nanoemulsiilor încărcate cu naringenină și ICG în prezenţa serului 97

4.3.3. Eficienţa radiantă a ICG încorporat în nanoemulsii 99

4.3.4. Biodistribuţia nanoemulsiilor încărcate cu naringenină în modelul de inflamaţie murină indusă de LPS 100

4.3.4.1. Biodistribuţia nanoemulsiilor încărcate cu naringenină evaluată prin eficienţa radiantă a ICG 100

4.3.4.2. Biodistribuţia nanoemulsiilor încărcate cu naringenină evaluată prin dozarea naringeninei prin UHPLC 108
4.4. Discuţii 110
4.5. Concluzii 115
CAPITOLUL 5-VALIDAREA IN VIVO A EFECTELOR ANTI-INFLAMATOARE ALE NANOEMULSIILOR LIPIDICE INCĂRCATE CU NARINGENINĂ 116
5.1. Introducere și obiective 116
5.2. Materiale si metode 116
5.2.1. Reactivi 116
5.2.2. Prepararea și caracterizarea nanoemulsiilor neţintite și tintite către VCAM-1, încărcate cu naringenină 117
5.2.3. Real Time PCR 117
5.2.4. Designul primerilor 118
5.2.5. Analiza statistică 118
5.2.6. Design experimental -Modelul experimental de inflamaţie acută indusă de LPS 118
5.3. Rezultate 119
5.4. Discuţii 126
5.5. Concluzii 130
CONCLUZII GENERALE 131

Participarea la proiecte de cercetare naţionale legate de tematica tezei de doctorat- 1

Introducere și obiective

Bolile cronice inflamatorii reprezintă cauza cea mai importantă a mortalităţii globale. La nivel mondial, peste 50% din populaţie suferă decese datorate atacurilor vasculare cerebrale, bolilor cronice respiratorii, cardiovasculare, cancerului, obezităţii și diabetului.

Procesul cronic inflamator este implicat în numeroase patologii aparent neînrudite, ca o caracteristică unificatoare ce pare să le conecteze dincolo de diversitatea fenotipică. *Mai probabil o cauză decât un efect*, inflamaţia de intensitate redusă, dar persistentă (cronică) este asociată cu așa-numitele „boli ale civilizaţiei" precum bolile cardiovasculare, cancerul, boala obstructivă pulmonară cronică, diabetul, patologia neurodegenerativă. Conform statisticilor Organizaţiei Mondiale a Sănătăţii, patologiile menţionate se situează între primele cinci cauze ale mortalităţii la nivel global.

Având în vedere importanţa procesului inflamator în evoluţia diferitelor disfuncţii, noi termeni precum inflamaţia metabolică - „metaflamaţia" și inflamația asociată îmbătrânirii (în limba engleză „inflammageing") au fost introduși recent în vocabularul medical pentru a descrie legătura dintre inflamaţie și bolile cronice metabolice (diabet de tip II, obezitate) și, respectiv, implicarea inflamaţiei în procese fiziologice cum ar fi îmbătrânirea.

Actualmente, compușii anti-inflamatori de sinteză, steroidici și nesteroidici, reprezintă tratamentul de elecţie. Cu toate acestea, utilizarea acestora atrage variate efecte secundare nedorite.

În ultimele decenii, compușii fitochimici au atras interesul ca alternativă la medicaţia convenţională datorită profilului lor toxicologic sigur și acţiunii terapeutice în diferite boli. Dintre acești compuși, polifenolii-sub formă de compuși purificaţi sau ca extracte din diferite surse naturale-oferă numeroase oportunităţi terapeutice, prin inhibarea unor căi de semnalizare pro-inflamatoare.

Printre limitările utilizării terapeutice a polifenolilor pe scară largă sunt hidrosolubilitatea scăzută și, subsecvent, biodisponibilitatea redusă la administrare orală. Încorporarea acestor principii active în nanoparticule ar putea înlătura dezavantajele menţionate, mai ales în condiţiile dezvoltării de terapii pentru livrarea direcţionată a compușilor bioactivi la situsurile inflamate, limitând atât disiparea substanţei utile în circulaţia sistemică, cât și efectele secundare nedorite.

În acest context, endoteliul vascular reprezintă o ţintă atractivă pentru nanoparticulele funcţionalizate către moleculele de adeziune ce sunt supraexprimate pe suprafaţa celulei în condiţiile activării de către diferiţi agenţi stresori.

Având în vedere efectele anti-inflamatorii benefice descrise pentru flavonoidele din citrice-naringenină și hesperetină, s-a preconizat că prin încorporarea într-un nanotransportor, direcţionat specific prin administrare intravenoasă către situsurile vasculare inflamate, acești compuși ar avea o eficacitate terapeutică crescută.

Anterior, în cadrul Laboratorului de Nanoterapii, liposomi directionaţi către molecula de adeziune VCAM-1 au fost eficienţi în ţintirea și reducerea activării endoteliului în ateroscleroză și cancer. Pe baza acestor date, a fost formulată ipoteza conform căreia, încapsularea celor două flavonoide, naringenina și hesperetina, în nanoemulsii lipidice direcţionate către VCAM-1 ar putea fi utilizată pentru reducerea inflamaţiei induse de TNF-α în celulele endoteliale.

În lucrarea de faţă ne-am propus și am realizat următoarele **obiective**: (**1**) conceperea, prepararea și caracterizarea de nanoparticule lipidice în scopul folosirii lor ca vectori pentru transportul ţintit de polifenoli, cum sunt flavonoidele din citrice, naringenina și hesperetina; (**2**) încărcarea nanoparticulelor cu polifenolii menţionaţi la obiectivul 1 și funcţionalizarea acestora în vederea direcționării lor către o țintă moleculară relevantă în inflamația vasculară, anume molecula

de adeziune celulară VCAM-1; (**3**) validarea preclinică a nanoparticulelor lipidice, încărcate cu polifenoli, ca vectori anti-inflamatori prin studii *in vitro* și *in vivo*.

Structura tezei de doctorat

Lucrarea este structurată în două părți principale, subdivizate în capitole.

Prima parte, alcătuită din două capitole, reprezintă o trecere în revistă a literaturii de specialitate și analizează stadiul actual al cunoștințelor privind inflamația și utilizarea polifenolilor încorporați în nanoparticule în terapia anti-inflamatorie. **Capitolul 1** se referă la mecanismele celulare și moleculare ale cascadei inflamatorii și la abordările terapeutice actuale care țintesc aceste evenimente. Sunt menționate principalele clase de agenți anti-inflamatori: glucocorticoizi, medicamente nesteroidice, statine, agenți biologici (inhibitori de citokine) și mecanismul acțiunii acestora. **Capitolul 2** reprezintă o recenzie a literaturii de specialitate referitoare la utilizarea polifenolilor încorporați în nanosisteme în scopuri anti-inflamatorii. Polifenolii reprezintă o clasă extinsă de compuși, metaboliți secundari ai plantelor, cu numeroase efecte terapeutice, anti-oxidante și anti-inflamatoare, antimicrobiene, anti-tumorale, anti-angiogenice și imunomodulatoare. Utilizarea terapeutică pe scara largă este însă împiedicată de hidrosolubilitatea și biodisponibilitatea scăzute. O strategie pentru îmbunătăţirea biodisponibilităţii o reprezintă încorporarea polifenolilor în diferite formule de nanoparticule: liposomi, nanoemulsii. O serie de studii clinice au demonstrat că biodisponibilitatea polifenolilor poate fi îmbunătăţită semnificativ prin nanoformulare. Studii preclinice și clinice au arătat efectele benefice ale polifenolilor încorporaţi în nanoparticule în diverse modele experimentale sau pacienţi cu condiţii inflamatorii associate, date fiind disponibile cu precădere pentru curcumină și resveratrol. Datele recenzate recomandă nanotehnologia ca o soluţie atractivă pentru a maximiza efectele terapeutice ale compușilor anti-inflamatori naturali, pentru o mai promptă utilizare clinică. De asemenea se evidențiază necesitatea explorării unei game mai diverse de compuși. Recenzia realizată în **Capitolul 2** a fost publicată în anul 2020 sub forma unui capitol de carte [**1**].

Partea a doua a lucrării cuprinde contribuțiile originale, organizate în trei capitole.

Capitolul 3 prezintă un studiu referitor la efectele anti-inflamatoare *in vitro* ale flavonoidelor din citrice-naringenină și hesperetină-încorporate în nanoemulsii lipidice utilizând linia de celule endoteliale umane EA.hy926.

Naringenina și hesperetina, principalele flavonoide din fructele citrice, fie în formă liberă, sau ca glicozide prezente în mod natural, sunt intens investigate în prezent pentru potenţialul terapeutic în ateroscleroză și diabetul de tip II, două din patologiile cu răspândire pandemică la nivelul societăţilor dezvoltate. Aceste flavonoidele exercită un spectru larg de activităţi: anti-oxidante, anti-inflamatoare, de reducere a glicemiei și lipemiei și îmbunătăţire a parametrilor metabolici: corectează dislipidemia, cresc toleranţa la glucoză și responsivitatea la insulină, reduc inflamaţia și adipozitatea.

O serie de studii anterioare din literatură au descris încorporarea acestor compuși în nanoparticule destinate mai ales administrării orale. Puţine încercări de direcţionare specifică a flavonoidelor din citrice la situsuri patologice în vederea creșterii concentraţiei locale efective au fost raportate în literatură. La momentul inițierii cercetărilor nu existau studii referitoare la nanoparticule direcționate conținând naringenină destinate administrării intravenoase.

În studiul prezentat în **Capitolul 3** este descrisă încorporarea naringeninei și hesperetinei, flavonoide cu hidrosolubilitate scăzută, în nanoemulsii lipidice. În plus, nanoparticulele au fost direcționate specific către molecula de adeziune celulară VCAM-1, supraexprimată pe suprafața endoteliului activat. Nanoemulsiile au fost testate funcțional *in vitro*.

Principalele rezultate:

- S-a reușit încorporarea flavonoidelor cu eficiență ≥ 80%, iar nanoemulsiile au prezentat stabilitate bună *in vitro* în condițiile menținerii timp de 3 luni la 4ºC sau o săptămână la 37 ºC.
- Caracterizarea fizico-chimică a indicat dimensiuni ale nanoparticulelor de ~200 nm, independent de încărcarea cu flavonoid și cuplarea cu peptida de recunoaștere a VCAM-1, iar indicii de polidispersie de ~0.2 au indicat omogenitatea populațiilor.
- Potențialul zeta al nanoparticulelor nedirectionate s-a situat în jurul valorii de -30 mV. Cuplarea cu peptida de recunoaștere a VCAM-1 a deplasat valorile potențialului zeta spre valori mai negative, proporțional cu cantitatea de peptidă cuplată.
- Studiile de eliberare *in vitro* în modelul săculeţului de dializă au indicat că naringenina și hesperetina au fost eliberate din nanoemulsii cu o cinetică mai lentă decât compușii puri. Cinetica eliberării s-a desfășurat după un model Weibull (exponențială monofazică).
- Nanoemulsiile încărcate cu flavonoide nu au manifestat citotoxicitate *in vitro* pe linia de celule endoteliale umane EA.hy926 la concentrațiile testate (25, 50, 100 µM) și au prezentat hemocompatibilitate la șoareci apoE deficienţi și C57/Black6.
- Nanoemulsiile încărcate cu flavonoide, neţintite sau ţintite către endoteliu, sunt preluate de celulele endoteliale umane din linia EA.hy926 într-o manieră dependentă de doză și timp, dar dependentă de TNF-α doar în cazul endoteliului activat.
- Teste funcţionale au arătat că flavonoidele încorporate în nanoemulsii, la o concentrație de 50 µM, au inhibat atât adeziunea cât și transmigrarea monocitelor THP-1 la/printre celulele endoteliale activate, printr-un mecanism care implică scăderea expresiei la nivel de genă și proteină a chemokinei pro-inflamatorii MCP-1 și reducerea translocării nucleare a NF-κB. Efectele au fost mai pronunțate în cazul nanoparticulelor direcționate.

Rezultatele acestui studiu au fost publicate în revista *Pharmaceutics* (factor de impact 4,773) [**2**].

În studiul prezentat în **Capitolul 4** am investigat biodistribuţia nanoparticulelor ce încorporează naringenină într-un model experimental de inflamaţie acută indusă de LPS. Deoarece naringenina ca atare nu prezintă caracteristici spectrale care să permită evaluarea localizării nanoparticulelor *in situ*, pentru marcare am utilizat trasorul de domeniu infraroșu apropiat Indocyanine Green (ICG) și am încercat să stabilim o corelaţie între distribuţia fluorescenţei ICG prin IVIS și concentraţiile de naringenină dozate prin HPLC. ICG este un trasor intens investigat în prezent datorită tropismului pentru sistemul cardiovascular, ca alternativă la tehnici invazive și/sau toxice de investigaţie. Combinaţia naringenină/ICG în nanocăraușI nu a mai fost raportată în literatură și domeniul utilizării ICG în urmărirea biodistribuţiei unor substanţe active încorporate în nanosisteme de transport este unul de mare actualitate.

Principalele rezultate:

- Pentru evaluarea potenţialului de ţintire al nanoparticulelor încărcate cu naringenină și direcţionate către molecula de adeziune celulară VCAM-1, am obţinut în premieră nanoparticule ce co-incorporează naringenină și trasorul NIR Indocyanine green (ICG). S-au obținut nanoemulsii

stabile timp de 3 luni la 4ºC, conținând naringenină și ICG, nedirecționate sau direcționate la VCAM-1.

- Dimensiunile nanoparticulelor au fost ~220 nm, iar potențialul zeta a fost de ~ -40 mV.
- Nu s-au evidențiat modificări ale potențialului zeta datorită funcționalizării cu peptida de recunoaștere a VCAM-1, spre deosebire de cazul nanoemulsiilor ce conțin doar naringenină.
- ICG încorporat în nanoemulsii a prezentat un semnal liniar de fluorescență pe domeniul 0-60 µM. Deși eficiența radiantă a fost de 10 ori mai scăzută decât a rodaminei, liniaritatea semnalului a fost superioară.
- Nanoemulsiile cu ICG și naringenină au fost stabile în prezența serului murin la 37ºC *in vitro*.
- Pentru urmărirea biodistribuției nanoparticulelor, acestea au fost administrate intravenos într-un model experimental de inflamație indusă cu LPS la șoareci C57/Black6. Nanoemulsiile s-au distribuit nespecific în ficat, rinichi, plămâni, splină, creier, așa cum s-a demonstrat prin analiza *ex vivo* a organelor prin tehnica IVIS. Nanoemulsiile s-au distribuit specific la nivelul segmentului (inimă+aortă), ca și în aortele individuale. Distribuirea selectivă a fost atribuită funcționalizării cu peptida de recunoaștere a VCAM-1, deoarece în aceleași condiții ICG liber s-a distribuit nespecific, iar nanoemulsiile au fost echivalente din punct de vedere al dimensiunilor și potențialului zeta, singura diferență constând în prezența peptidei de cuplare.
- Evaluarea concentraţiei de naringenină prin UHPLC a indicat o corelație satisfăcătoare cu datele de fluorescență, iar cauzele anumitor discrepanțe sunt analizate.

Coroborate, aceste date susţin utilitatea nanoparticulelor încărcate cu ICG în urmărirea localizării după administrarea intravenoasă la șoarece. În plus, ele arată că nanoparticulele ţintite către VCAM-1 s-au localizat preferenţial în anumite situsuri ale endoteliului activat, unde au eliberat agentul activ.

Capitolul 5 se referă la studiul efectelor anti-inflamatoare ale nanoparticulelor încorporând naringenină *in vivo* într-un model experimental de inflamaţie indusă de LPS. Rezultatele experimentelor de qRT-PCR pe organe prelevate de la șoareci cu inflamaţie indusă de LPS au confirmat potenţialul terapeutic al naringeninei încorporate în nanoemulsii. Datele noastre arată la animalele tratate cu nanoparticule ţintite, o reducere a expresiei genice a unor markeri inflamatori precum TNF-α, IL-1β. MCP-1, RANTES, VCAM-1 și ICAM-1. Sumarul cazurilor în care nanoemulsiile încărcate cu naringenină au avut un efect mai puternic în reducerea expresiei genice a markerilor inflamatorii în varianta ţintită către VCAM-1 comparativ cu cea neţintită este prezentat în Tabelul 1.

Molecula	Diferenţe cu semnificaţie statistică	Diferenţe fără semnificaţie statistică
TNF-α	rinichi	Inimă, plămâni, creier
IL-1β	plămâni	Inimă
MCP-1		Rinichi, plamân, splină, creier, inimă
RANTES	creier	Plamâni, inimă
VCAM-1	plămâni	Splină, inimă
ICAM-1		Plamâni, inimă, creier

Tabelul 1. *Sumarul cazurilor în care nanoemulsiile încărcate cu naringenină au avut un efect mai puternic în varianta ţintită către VCAM-1 comparativ cu cea neţintită în reducerea expresiei genice a markerilor inflamatori evaluați.*

Deși diferenţe statistice semnificative între nanoemulsiile ţintite către VCAM-1 și cele neţintite s-au înregistrat doar în câteva situaţii punctuale (IL-1β în plămâni, TNF-α în rinichi, RANTES în creier, VCAM-1 în plămâni), totuși evaluarea de ansamblu a panelului de markeri inflamatori indică o tendinţă anti-inflamatoare.

Această lucrare aduce următoarele **contribuţii originale**:

(i) conceperea și caracterizarea nanoemulsiilor lipidice care încorporează flavonoide din citrice;
(ii) funcţionalizarea acestora cu o peptidă de recunoaștere a moleculei de adeziune VCAM-1;
(iii) demonstrarea preluării specifice a nanoemulsiilor direcţionate la VCAM-1 de către celule endoteliale umane activate cu TNF-α;
(iv) validarea activităţii anti-inflamatoare *in vitro* prin reducerea adeziunii și transmigrării monocitelor la/prin endoteliu;
(v) conceperea și caracterizarea nanoemulsiilor lipidice încărcate cu naringenină și etichetate fluorescent prin co-încorporarea fluorocromului NIR, Indocyanine Green;
(vi) urmărirea ţintirii specifice a endoteliului *in vivo* folosind un model murin de inflamaţie, pe baza determinării fluorescenţei NIR a nanoemulsiilor lipidice;
(vii) validarea *in vivo* a efectelor anti-inflamatoare ale nanoemulsiilor încărcate cu naringenină.

Introduction and objectives

The increase in human longevity has stimulated the interest of scientists to understand the fundamental mechanisms underlying natural aging. Ageing is a complex and still insufficiently understood phenomenon, involving a gradual decline in cellular and organ function that leads to higher incidence of chronic diseases. Numerous genetic and epigenetic modifications, as well as imbalances in biochemical processes, are tightly linked to ageing, some of which are now reorganized as hallmarks of this process (Gupta et al., 2014). According to *World Heart Report, 2023*, although the age-standardized mortality rate has decreased by one third between 1990 and 2019, cardiovascular diseases remain the leading cause of death in the world, with the number of deaths increasing by 33% over the last 30 years.

Structural and functional alterations of the heart that occur during ageing may ultimately result in heart failure (North and Sinclair, 2012). The major manifestations of cardiac ageing include fibrosis (Biernacka and Frangogiannis, 2011), chronic inflammation (Ferrucci and Fabbri, 2018), hypertrophy (Olivetti et al., 2000), and impaired angiogenesis (Lähteenvuo and Rosenzweig, 2012). When studying cardiac structure and function, most attention is traditionally given to cardiomyocytes, despite the fact that non-myocyte cells represent the majority of the heart cellular population. Among these, cardiac fibroblasts form a heterogeneous and dynamic group with essential structural and functional roles in cardiac homeostasis, both under physiological and pathological conditions. Cardiac fibroblasts account for approximately 15% of the total cell population in the adult murine myocardium, are interspersed among cardiomyocytes, and possesses a specific molecular programme that enables them to rapidly integrate and respond to extra cellular cues following injury (Tallquist and Molkentin, 2017). Activation of fibrotic signalling pathways in response to ageing related stress leads to cardiac fibrosis and hypertrophy. These are two key features of cardiac ageing that are strongly interconnected and mutually triggered by each other. Consequently, cardiac ageing is often associated with diastolic dysfunction and heart failure with preserved ejection fraction (HFpEF), which has a negative effect in the elderly population(Singam et al., 2020).

Myocardial infarction (MI) is one of the most devastating cardiovascular events. Ageing not only increases the risks of MI but also worsens post-infarction outcomes, as aged hearts exhibit impaired angiogenesis, inefficient resolution of inflammation, and reduced regenerative capacity (Olivetti et al., 1991, Dai et al., 2012). This processes ultimately drive

maladaptive myocardial remodelling. A central feature of this remodelling is cardiac fibrosis, defined by excessive deposition of extracellular matrix (ECM) proteins,particularly collagen. While fibrosis initially stabilizes the injured myocardium, excessive ECM accumulation compromises ventricular compliance, disrupts electrical conduction, and eventually contributes to heart failure (Travers et al., 2016).

Cardiac fibroblasts are the main contributors to post-MI fibrosis, but they also influence other aspects of healing, including inflammation (Theall and Alcaide, 2022) and scar maturation (Daseke et al., 2020). Thus, dysregulated activation of cardiac fibroblasts in the early stages of injury can therefore result in defective healing and worsened cardiac performance. In the later phases, the fibrotic scar-initially crucial for survival, undergoes extensive crosslinking, which increases tensile strength but compromises contractility(Deb and Ubil, 2014). These processes ultimately contribute to systolic dysfunction and chronic heart failure (Smolgovsky et al., 2021).

Increasing evidence highlights the important role of microRNAs (miRNAs) in cardiovascular pathologies associated with ageing. Some miRNAs display pro-fibrotic activity, while others exert anti-fibrotic effects in MI and fibrotic remodelling in the aged hearts. The discovery of the association between miRNAs and some diseases has fueled the interest in their therapeutic potential as a novel class of drugs. Moreover, the global success of mRNA vaccines against SARS-CoV-2 has further increased the interest for RNA-based therapies, which are now emerging as a real treatment option (Seyhan, 2024).

Based on these considerations, our **hypothesis** is that dysregulation of the miRNAs expression profile during ageing disrupts the molecular mechanisms that maintain homeostasis, and leads both to systemic functional decline and to the initiation of pathological processes such as cardiac fibrosis and maladaptive post-MI remodelling. Thus, the **aim** of this thesis was to explore the role of miRNAs as key regulators of cellular homeostasis and as potential therapeutic targets capable of counteracting pathological processes such as ECM remodelling and cardiac fibrosis. By doing so, this work contributes to the identification of innovative strategies to promote healthy ageing and prevent age-associated complications. To achieve this aim, the research carried out during my doctoral studies pursued the following **specific objectives**:

1. To identify the expression profile of miRNAs involved in the pathophysiology of the cardiovascular system in individual cardiac cell populations isolated from aged mice;

2. To assess the in vitro effects of ageing-associated miRNAs on cardiac fibroblasts, focusing on their impact on the pro-fibrotic phenotype and signalling pathways related to ageing (inflammation and tissue remodelling);

3. To determine the therapeutic potential of miRNA modulation on post-MI the maladaptive remodelling in the ageing heart.

Thesis structure

The doctoral thesis is organised into two main parts:

Part 1 - Current state of knowledge is divided into 3 main chapters**. Chapter 1**, "*The role of ageing in the onset of cardiovascular diseases*", addresses general future of ageing, cardiac alterations associated with ageing, and finally, Age-related cardiac remodeling after ischemic heart disease. **Chapter 2**," *The cardiac fibroblast*", highlights aspects of the cardiac fibroblast, from its general characteristics to its role in cardiac homeostasis and fibrosis. Finally, **Chapter 3** focuses on "*The role of miRNAs in cardiac ageing and ageing-related pathologies*". This chapter provides a synthesis of the literature regarding miRNAs nomenclature and genomic organization, their biogenesis, mechanisms of action, and their dysregulation in cardiac ageing and age-related cardiovascular diseases. At last, the chapter reviews several preclinical studies regarding the use of miRNAs in cardiac fibrosis therapy.

Part 2 - Original contributions, presents the original results obtained in the studies carried out to fulfil the objectives of the thesis. It is divided into three chapters, whose main results and conclusions are summarised below:

Chapter 1- MIRNAs INVOLVED IN NATURAL AGEING: IMPACT ON CARDIOVASCULAR DISEASES, includes the study" *MiR-29a increase in ageing may function as a compensatory mechanism against cardiac fibrosis through Serpinh1 downregulation*". In this work, we focused on identifying the roles of four miRNAs (miR-18a, miR-21, miR-22 and miR-29a), known to be involved in cardiovascular diseases during ageing. Using molecular biology, biochemical techniques and cell culture models, we showed that cardiac ageing is associated with increased expression of miR-18a, miR-21a, miR-22 and miR-29a. To determine whether these changes are heart specific or represent a systemic hallmark of ageing, we also evaluated their expression in multiple organs collected from young and aged mice. The results showed that only miR-21a and miR-29a were

globally increased in ageing, and very interesting the expression level of miR-29a was higher that of miR-21a (Fig. 1B).

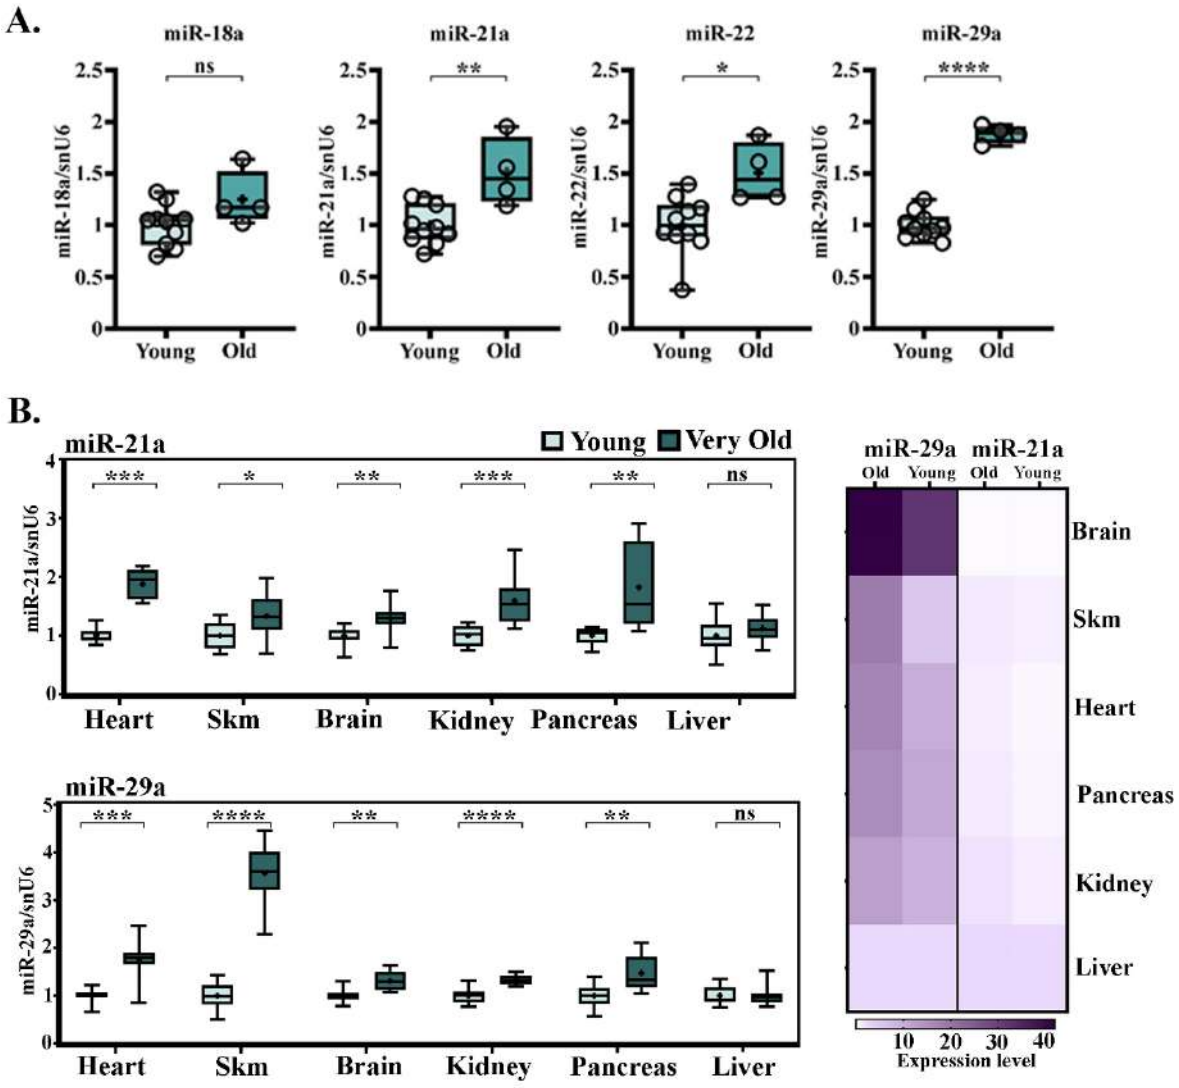

Figure 1. The evaluation of miRNAs involved in cardiac pathologies during natural ageing. (*A.) Evaluation of four miRNAs in the heart collected from young and aged mice; (B.) Assessment of miR-21a and miR-29a expression levels in multiple organs harvested from young and aged mice. The heatmap shows a higher expression of miR-29a compared to miR-21 across the analysed organs. Data are presented as 2-dCt values, with snU6 used*

These findings suggests that miR-29a might play a more important biological role in the ageing process, which prompted further studies focused on elucidating its function during ageing. Bioinformatic analysis revealed that miR-29a directly regulates *Extracellular matrix organization* by targeting *Serpinh1*, an essential collagen chaperone (Fig. 2A-B). Experimental validations confirmed *Serpinh1* as a direct target of miR-29a, and its

expression level was found negatively correlated with the elevated levels of miR-29a observed in aged organs (Fig. 2C).

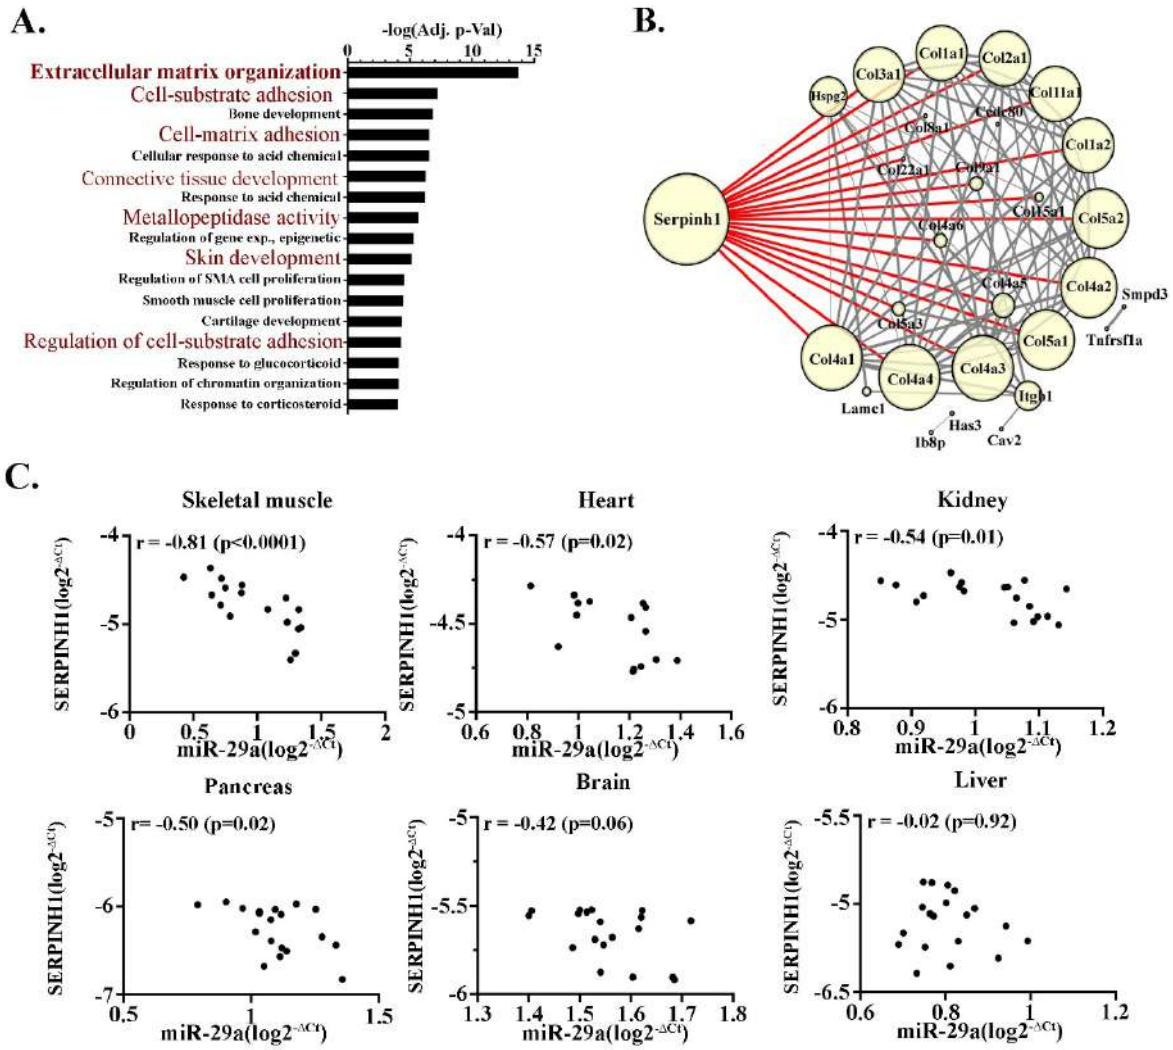

Figure 2. Identification of Serpinh1 as a target of miR-29a*. (A.) Bioinformatic analysis of biological processes deregulated by miR-29a; (B.) Protein-protein interaction (PPI) analysis identifying Serpinh1 as a central player in "ECM Organisation"; (C.) Pearson correlations between Serpinh1 and miR-29a expression levels as across six analysed organs;*

Finally, in vitro studies demonstrated that overexpression of miR-29a in fibroblasts and cardiac muscle cells inhibited cell proliferation and migration (Fig. 3A), and reduce the synthesis of pro-fibrotic molecules such as Collagen 1 and 3 (Fig. 3B). These findings suggest that miR-29a acts as a compensatory anti-fibrotic mechanism, capable of limiting pathological remodelling of the extracellular matrix.

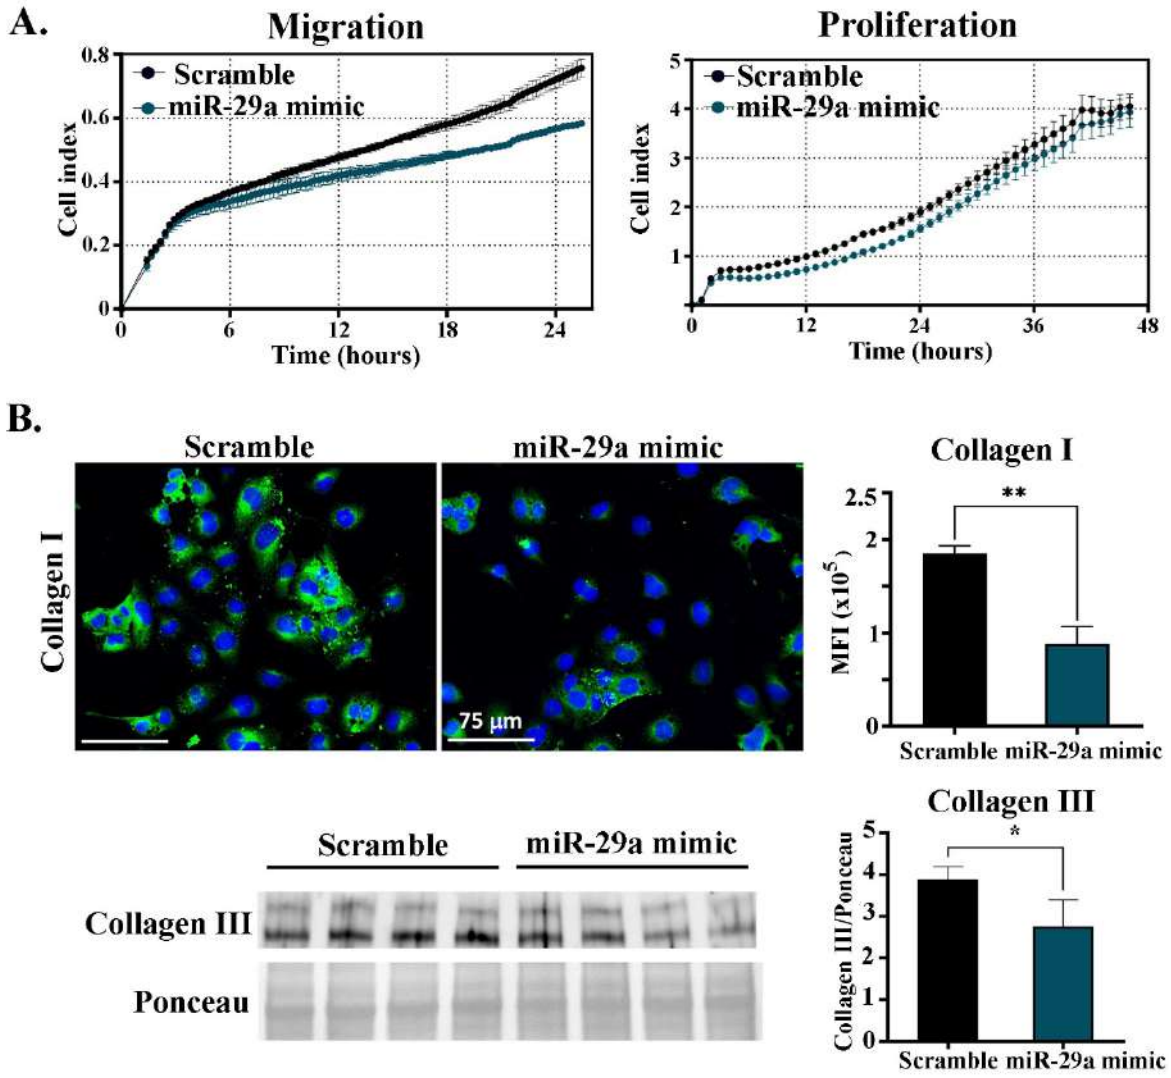

Figure 3. The antifibrotic role of miR-29a*. (A.) Real-time assessment of migration and proliferation in HL-1 cells following transfection with either a miR-29a mimic or scrambled miRNA control. Data represent one representative experiment out of three performed in quadruplicate with similar results; (B.) Quantification of collagen in HL-1 cells overexpressing miR-29a.*

Chapter 2-INVESTIGATION OF MIRNAs WITH REDUCED EXPRESSION IN CARDIAC FIBROBLASTS DURING NATURAL AGEING, comprises two studies:

Study 1 *–"Isolation and characterization of primary murine fibroblasts and cardiomyocytes"* aimed to obtain the highest number of viable and functional cardiac cells. Adult murine cardiomyocytes were isolated from young and old mice by retrograde perfusion through the aorta with a digestion buffer, which insured the uniform distribution of digestive enzymes through the coronary network, enabling an efficient digestion of

myocardial tissue. The isolated cells displayed typical rectangular morphology, being elongated and in some cases, branched (Fig. 4). To isolate cardiac fibroblasts, three enzymatic digestion protocols using different enzymes were standardized. Comparison of the three protocols revealed that fractionated digestion provided the best balance between yield, viability and cellular purity, allowing the reproducible isolation of a substantial number of cardiac fibroblasts. The fibroblasts exhibited typical mesenchymal morphology, with spindle-shaped or stellate forms.

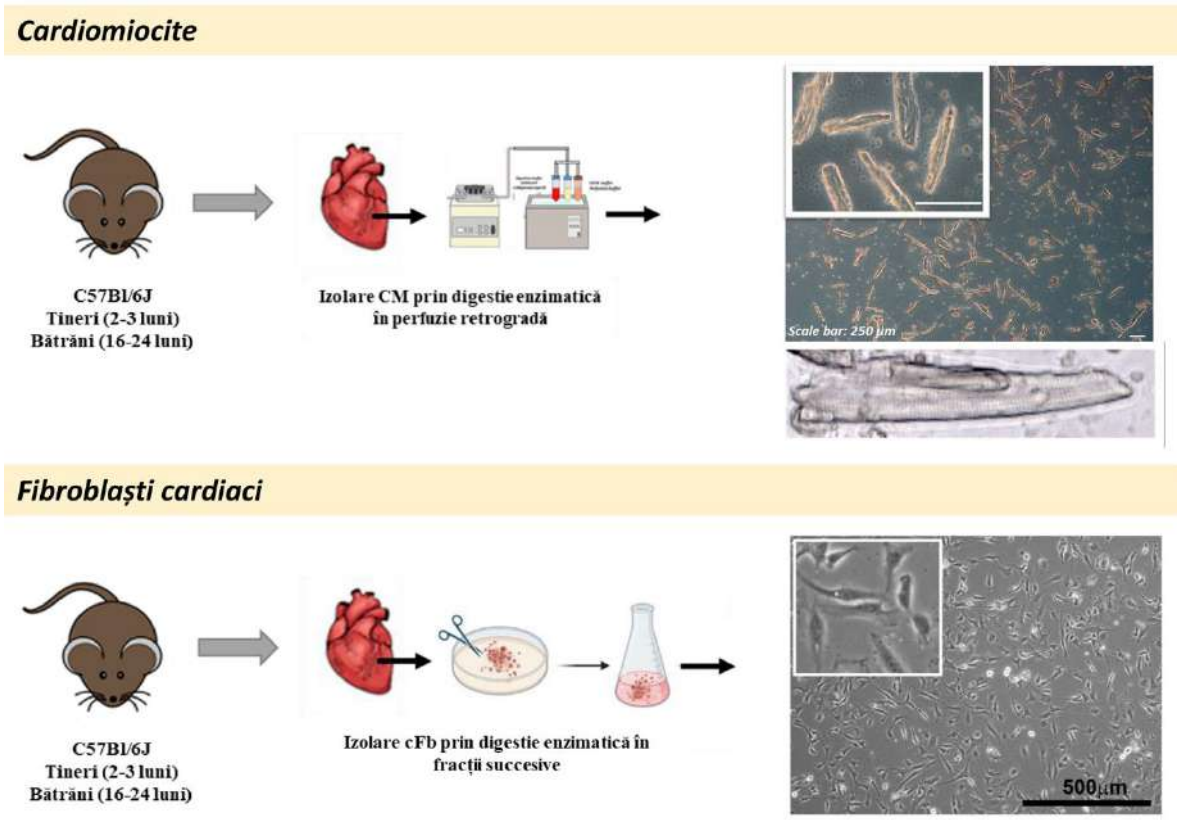

Figure 4. Isolation of cardiac cells*. Schematic illustrations of the experimental design for cardiomyocytes and cardiac fibroblast isolation. Representative images of cardiomyocytes after 1h in culture and cardiac fibroblast after 3 days in culture.*

Immunophenotypic characterization of cardiac fibroblasts by flow cytometry show that the cell suspension was depleted of CD45+ immune cells and CD31+ endothelial cells, while the majority of cells expressed Pdgfr-alpha, S100A4 and alpha-SMA, a well-established panel of cardiac fibroblast markers. Comparative analysis of fibroblast isolated from young and old mice reveal that the age associated phenotypic changes were moderate, but significant at the cellular level. Specifically, fibroblasts from old animals exhibited a slight increase in cell size (Fig. 5A), reorganisation of alpha-SMA (Fig. 5B) and a greater reliance

on glycolytic metabolism associated with a reduced adaptability to metabolic stress (Fig. 5C).

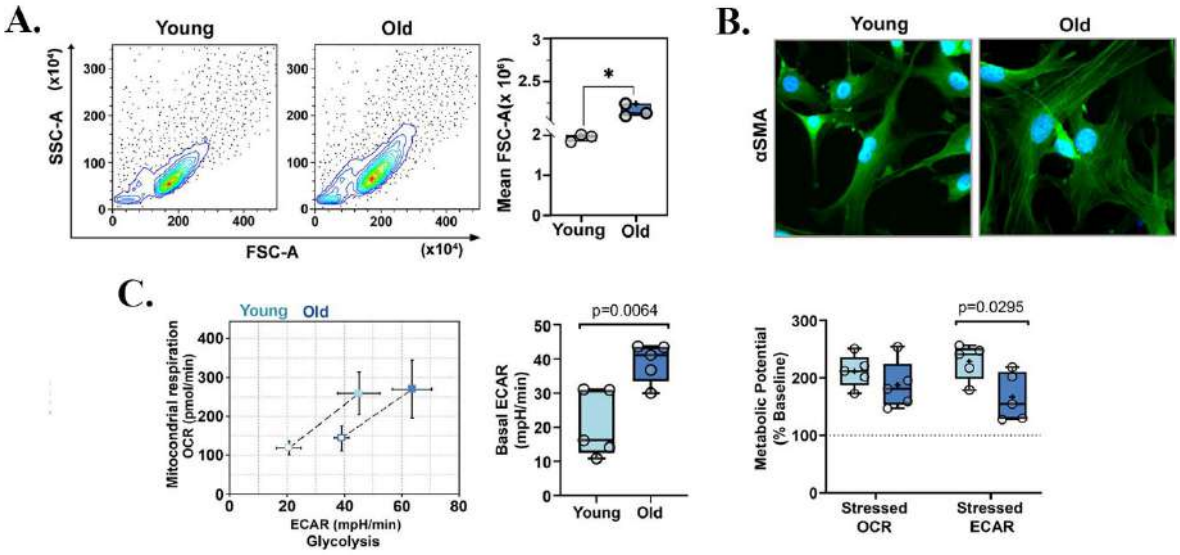

Figure 5. Differences in cardiac fibroblast derived from young and old mice. *(A.) Scatter plot showing the size of cardiac fibroblast from young and old mice; (B.) Fluorescence microscopy images showing differences in the distribution pattern of alpha-SMA protein (The pictures are representative from three experiments); (C.) Metabolic differences between young and old fibroblast under basal and stress conditions.*

Study 2-*"* MiRNAs generated from Meg3-Mirg locus are downregulated during aging". In this study, we demonstrated that natural ageing in cardiac fibroblast was associated with moderate changes in the expression of 88 miRNA, of which 60 show significant downregulation (Fig. 6A). To identify those miRNAs with significantly altered expression that may reliably reflect ageing-associated changes we map their genomic position and the frequency of steady, upregulated and downregulated miRNAs were interrogated for each chromosome. The results reveal that among the 60 downregulated miRNAs, 30 originated from the Meg3-Mirg locus on chromosome 12 (Fig. 6B). This locus consists exclusively of non-coding RNAs, i.e. 3 long-noncoding RNAs (Meg3, Rian, Mirg), several small nucleolar RNAs (C/D snoRNAs) and 57 miRNA genes (Fig. 6C).

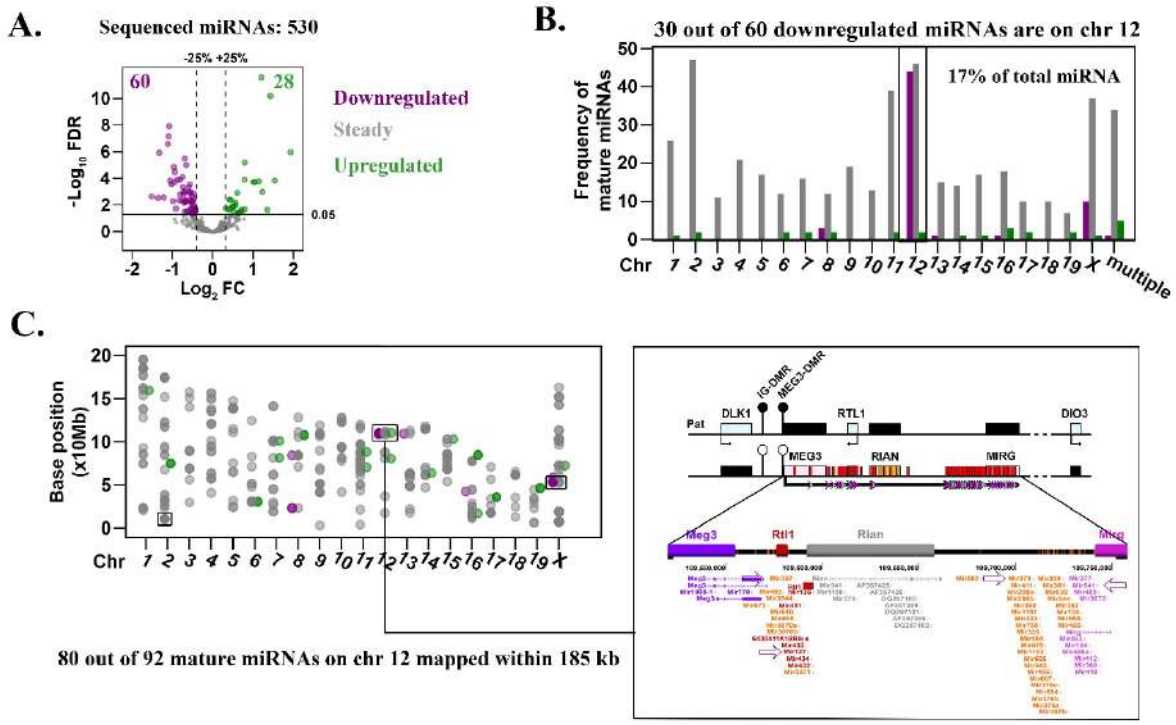

Figure 6. Identification of miRNAs in cardiac fibroblast isolated from young and old mice. *(A.) Volcano plot showing the analysis of differentially expressed miRNA; (B.) The frequency of mature miRNAs mapped to each mouse chromosome or to multiple chromosomes; (C.) The genomic location of mature miRNAs represented by the position at which the corresponding gene begins (mature miRNAs with multiple genomic locations were not showed) and schematic representation of the Meg3-Mirg locus as part of the paternally imprinted Dlk1-Dio3 locus. The Meg3-Mirg locus is maternally expressed and contain exclusively non-coding RNAs, namely lncRNAs (Meg3, Rian, Mirg), several snoRNAs (orange bar) and 57 miRNA genes (red bars). Representative miRNAs from the Meg3-Mirg cluster are highlighted with arrows.*

To determine whether the ageing associated downregulation of miARNs from the Meg3-Mirg locus is a feature specific to cardiac fibroblasts or also affected other organs or cardiac cell types, we selected four mature miARNs (miR-337-5p, miR-127-3p, miR-379-5p, miR-541-5p) as representative of the locus. These miARNs were chosen based on their genomic positions across the cluster and their consistent expression levels. The results demonstrated that natural ageing is associated with a coordinated repression of these four representative miRNAs (miR-337-5p, miR-127-3p, miR-379-5p, miR-541-5p), a phenomenon observed not only in cardiac fibroblasts, but also in other organs such as skeletal muscle, liver and cardiac ventricles (Fig.7).

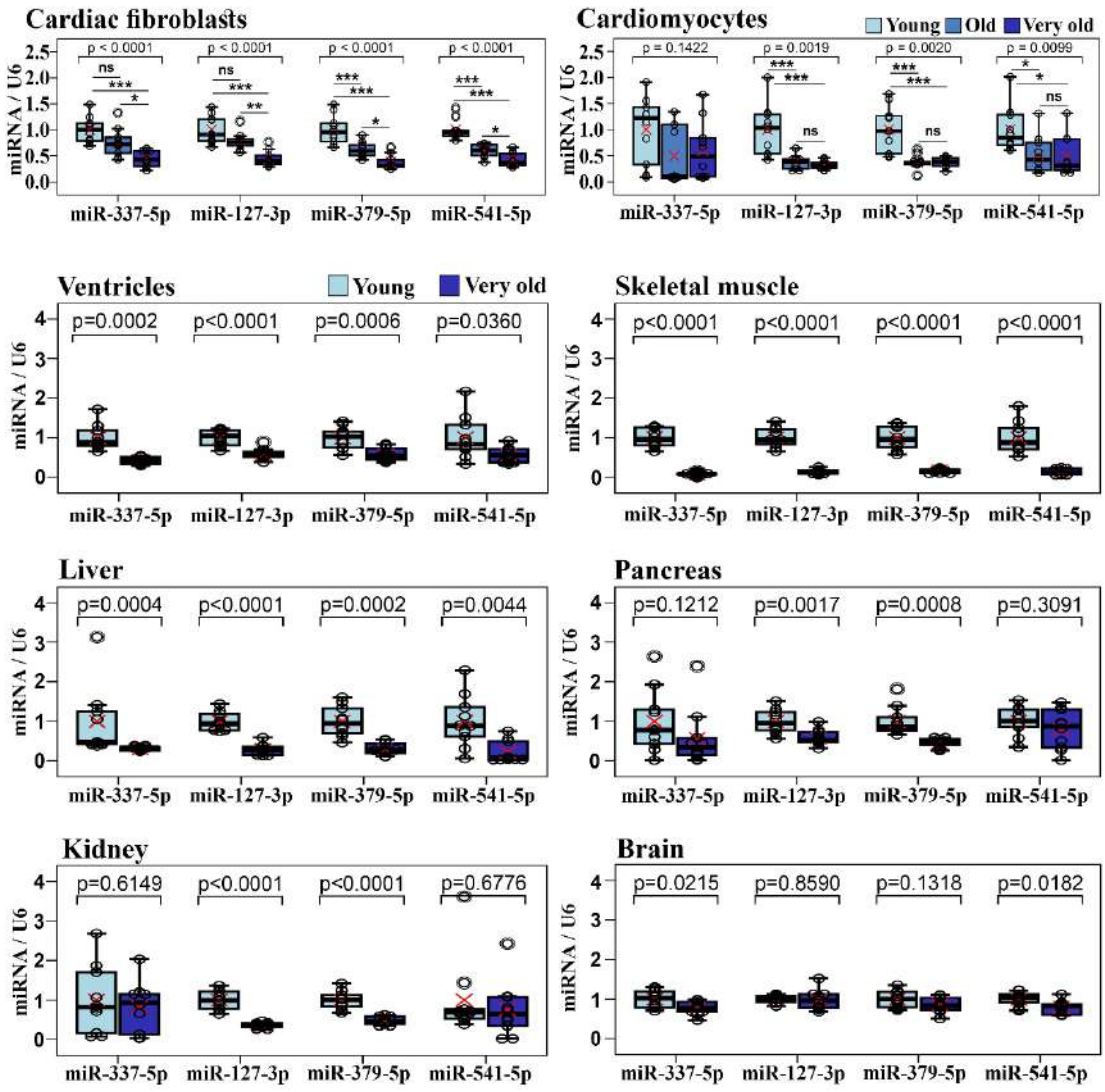

Figure 7. RT-qPCR Analysis of the four representative miRNAs from the Meg3-Mirg locus in cardiac cells and multiple organs collected from young and old mice. *For each miARN, the expression level is shown relative to the young group; n=8-10/group. Data are represented as mean* $2^{-\Delta\Delta Cq}$ *values, ± SD.*

Subsequently to determine the biological role of the downregulation of miRNAs from the Meg3-Mirg locus, 27 representatives of this locus were included in an in silico analysis to identify their predicted target genes. Bioinformatic analysis revealed that the predicted targets of all miRNAs were significantly enriched in KEGG pathways related to longevity, inflammation and fibrosis, suggesting a central role of this locus in regulated age-associated processes (Fig. 8A). Furthermore, by intersecting the target genes of the 27 miRNAs with the genes unregulated during ageing from the Tabula Muris Senis data set, we identify and validated Itgb2 (Fig. 8B-C) as a relevant target gene of Meg3-Mirg miRNAs, and found it

to be overexpressed in several aged organs (heart, brain, kidney pancreas and cardiac fibroblast).

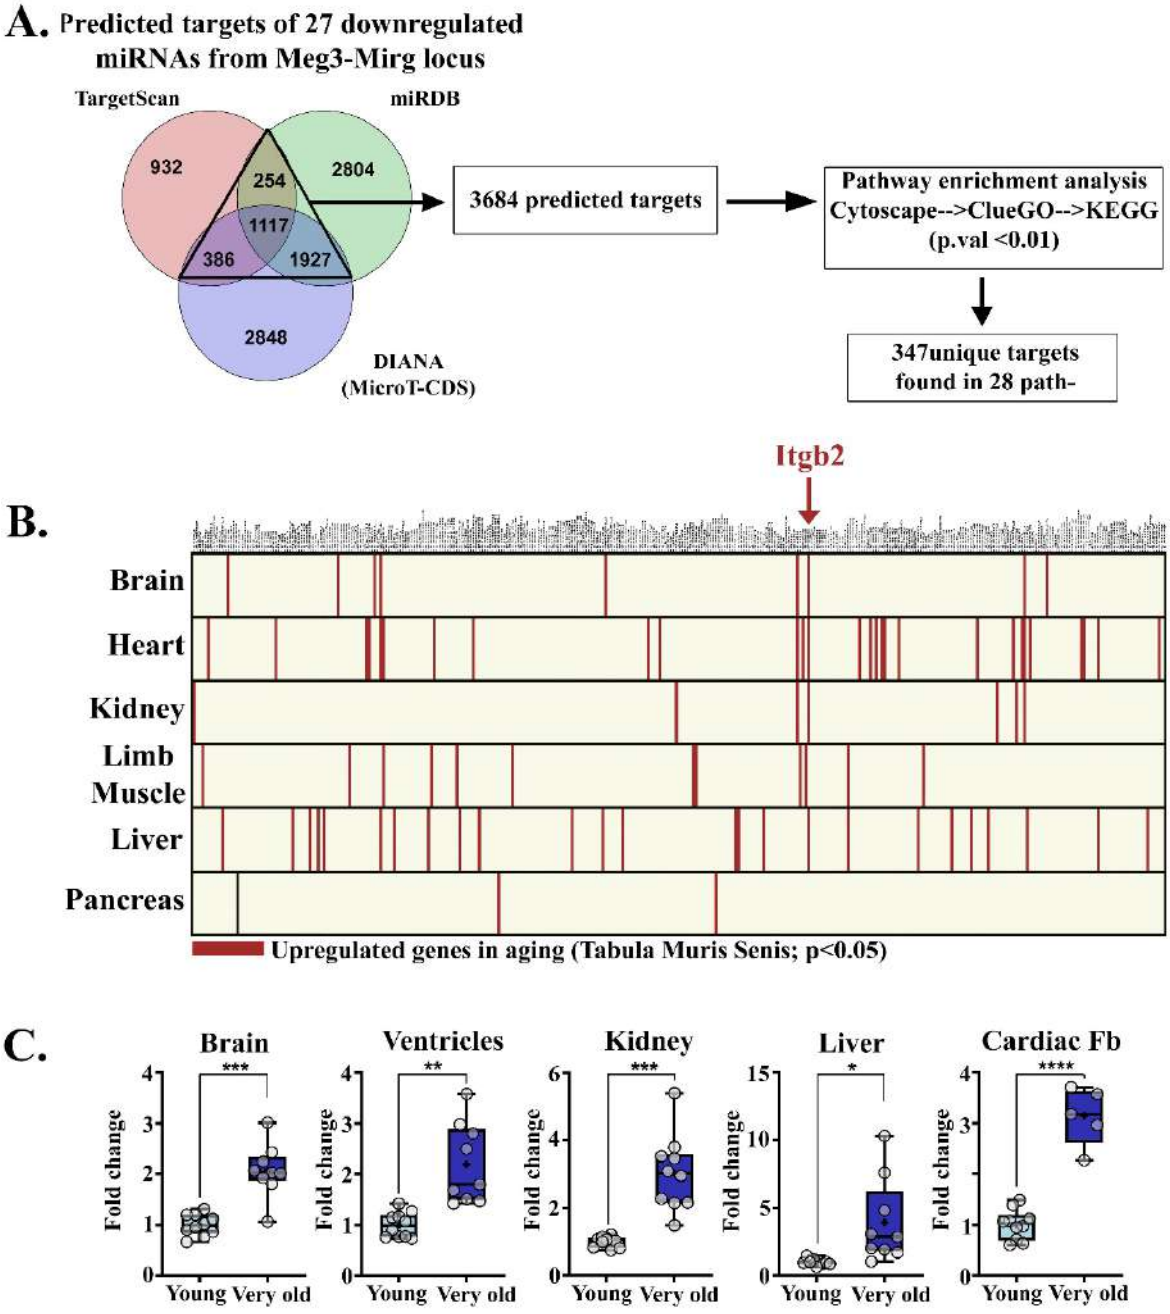

Figure 8. Gene upregulated during ageing that are targeted by the miRNAs from the Meg3-Mirg locus. *(A.) Venn diagram illustrating the predicted targets of 27 miRNAs; (B.) Graphical representation of the intersection between the unique gene identified in KEGG pathways and the genes that are upregulated in the Tabula Muris Senis database. Upregulated genes are highlighted for each organ. Itgb2 was identified as the only gene*

upregulated in 4 out of 6 organs; (C.) The expression Itgb2 gene in the brain, ventricles, kidney, liver and cultured cardiac fibroblasts.

Chapter 3 - INVESTIGATION OF MIRNAs WITH INCREASED EXPRESSION IN CARDIAC FIBROBLASTS DURING NATURAL AGEING. This chapter includes the study "*Activation of miR-10b in cardiac fibroblasts attenuates the adverse remodelling after myocardial infarction during aging by targeting Lpar2*". In this study, we focused on identifying the roles of the upregulated miRNAs in cardiac fibroblasts, in the process of post-MI remodelling during ageing. Using in vivo functional studies, molecular biology techniques, biochemistry, cloning and cell culture experiments, we identified miR-10b-5p as being overexpressed in cardiac fibroblasts (cFbs) during ageing (Fig.9A). The increase was also confirmed in the aged heart and was attributed exclusively to the accumulation of miR-10b in cardiac fibroblasts, and not in cardiomyocytes, suggesting an important role for this miRNA in the fibrotic remodelling process associated with ageing (Fig.9B).

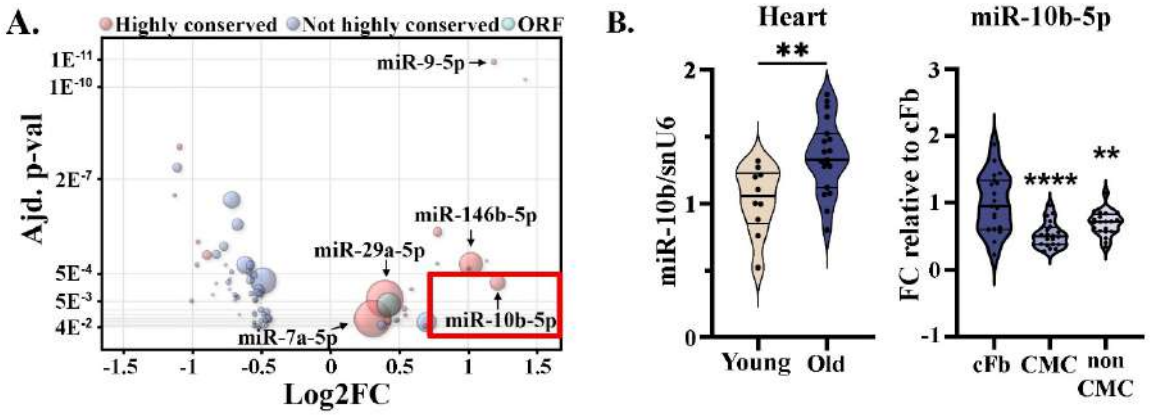

Figure9. Dysregulation of miR-10b expression during cardiac ageing. *(A.) Volcano bubble plot showing the dysregulated miRNAs in cardiac fibroblasts during ageing. Bubble size represents the mean expression level (RPM-reeds per million), while the colour indicates the conservation status: red= highly conserved (across vertebrates); blue= conserved only in mammals; (B.) Relative expression of miR-10b in the heart and isolated cardiac cells from young and old mice. N=10-20/group. Data are presented as mean* $2^{-\Delta\Delta Cq}$ *values ± SD.*

Thus, we hypothesized that miR-10b expression might also be altered in post-MI cardiac fibrosis. Our data showed that miR-10b exhibited a biphasic regulation during myocardial infarction being reduced during the inflammatory phase (1-3 days post-MI) and increased during the reparative/maturation phase (7-14 days post- MI) (Fig.10A-B). We showed that inflammatory signals such as TNF-alpha inhibited its expressions, thereby facilitating

fibroblast activation and matrix deposition. In contrast, increased levels of miR-10b in the presence of inflammatory stimuli promoted fibroblast apoptosis (Fig.10C). Furthermore, we demonstrated that in vitro overexpression of miR-10b in cardiac fibroblasts exerts an anti-fibrotic role by inhibiting their proliferation end migration and by reducing ECM molecules, such as *Ctgf* (Fig.10D-E). Collectively, these miR-10b - mediated processes may contribute to stabilising the post-MI scar and preventing excessive ECM accumulation.

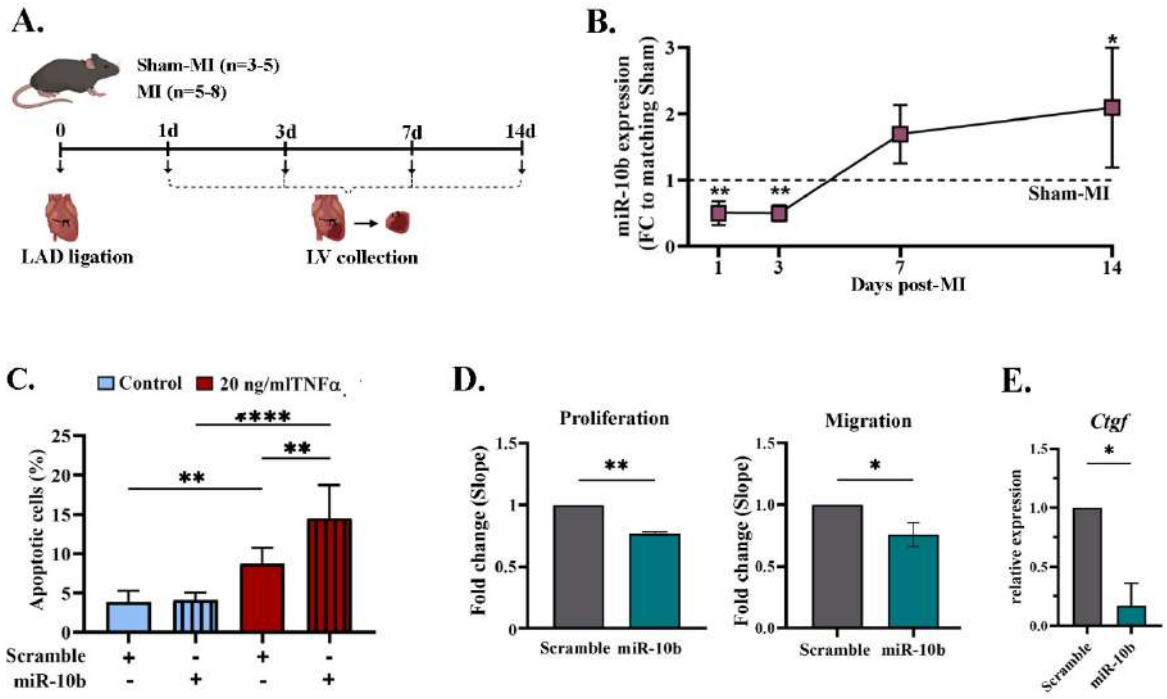

Figure10. The expressions and role of miR-10b during post-MI reparative phases. *(A.) Schematic representation of the experimental design. Myocardial infarction was induced in young C57Bl/6 mice (2-3 months) by ligation of the left anterior descending coronary artery (LAD). The infected region on the left ventricle was collected in liquid nitrogen at 1,3,7 and 14 days pos-MI; (B.) miR-10b expression at different time intervals after MI. Data are calculated relative to the corresponding Sham group at each collection time point (mean ±SD; n=3-9); (C.) The impact of miR-10b overexpression in 3T3 fibroblasts on cell apoptosis under inflammatory conditions; (D.) The effect of miR-10b on proliferation and migration of cardiac fibroblasts using the xCELLigence RTCA Biosensor system. Bar plots shows slope analysis describing the inclination, gradient and rate of change of the cell index curves measured over time. Three independent experiments were performed and slope results for each experiment were normalized to 1; (E.) Evaluation of Ctgf expression following miR-10b transfection in immortalized aged cardiac fibroblasts.*

To validate this hypothesis, we assessed the contribution of miR-10b in post-MI ventricular remodelling. For this purpose, we investigated the underlying mechanisms through which this miRNA influences ischemia-induced ventricular remodelling during aging. The results showed that miR-10b was upregulated in cardiac fibroblasts isolated 7 days post-MI from the infarcted region (Fig11A). Bioinformatic analysis and functional assays further identified Lpar2 as a direct target of miR-10b (Fig.11B). Accordingly, overexpression of miR-10b in aged cardiac fibroblasts reduced Lpar2 at both the transcript and protein level (Fig.11C), and luciferase reporter assays confirmed the direct miR-10b-Lpar2 interaction (Fig.11D). To further elucidate the molecular mechanisms by which the LPA/Lpar2-miR-10b axis regulates cardiac fibrosis, we explored the role of lysophosphatidic acid (LPA) in this process. LPA is a bioactive phospholipid with growth factor-like properties, known to stimulate cell proliferation, migration and survival. Moreover, LPA signalling, mediated through its receptors (Lparl-6), plays a significant role in the development of fibrosis.

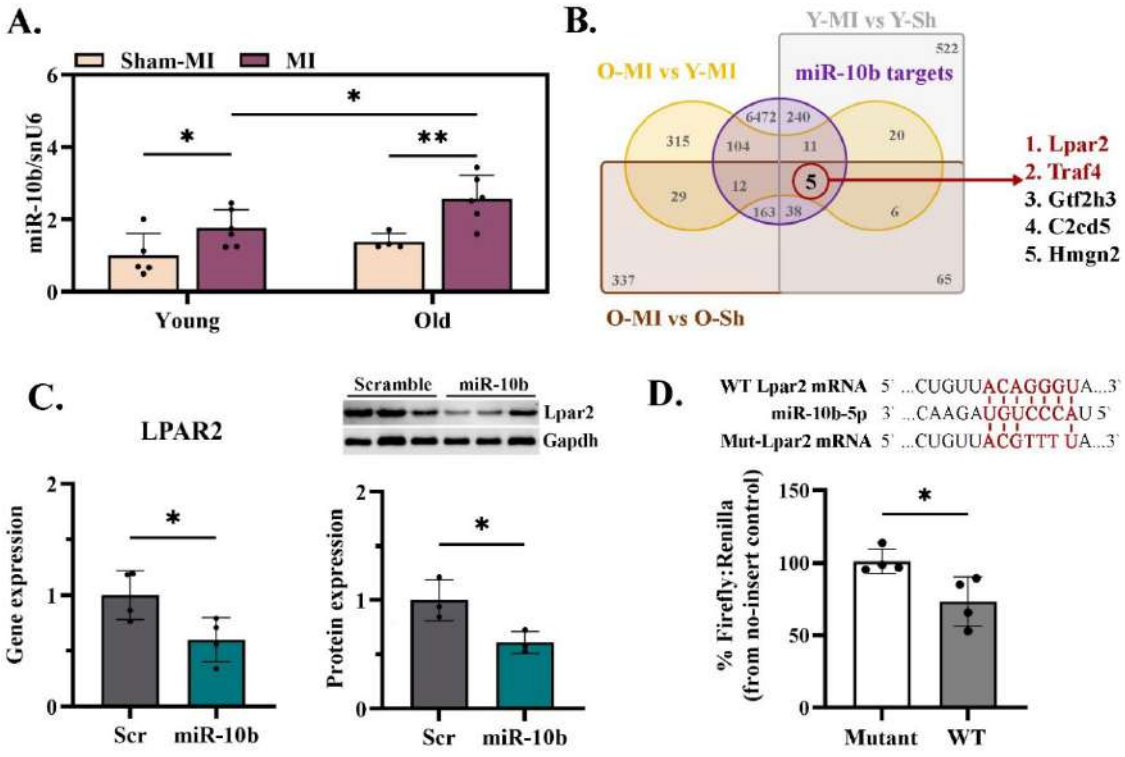

Figure11.Identification and validation of Lpar2 as a target of miR-10b. *(A.) RT-qPCR analysis of miR-10b expression in cardiac fibroblasts isolated from young and old mice 7 days post-MI; (B.) Bioinformatic analysis to identify target genes of miR-10b. The genes found downregulated in the experimental groups Y-MI vs Y-Sham, O-MI vs O-Sham and O-MI vs Y-MI were overlapped with the predicted miR-10b targets identified from four databases; (C.) Gene and protein expression of Lpar2 in old cardiac fibroblasts*

overexpressing miR-10b; (D.) Dual-luciferase reporter assay demonstrating the direct interaction between Lpar2 and miR-10b-5p. The pmiRGLO reporter plasmid containing the seed sequence of the Lpar2-WT or Lpar 2-Mut was co-transfected with miR-10b into HEK293 cells.

Functional essays showed that in the presence of a specific Lpar2 agonist, miR-10b overexpression reduced both proliferation (Fig.12A) and the expression of Collagen I and III genes (Fig.12B) in aged cardiac fibroblasts, further supporting the role of this pathway in fibrosis.

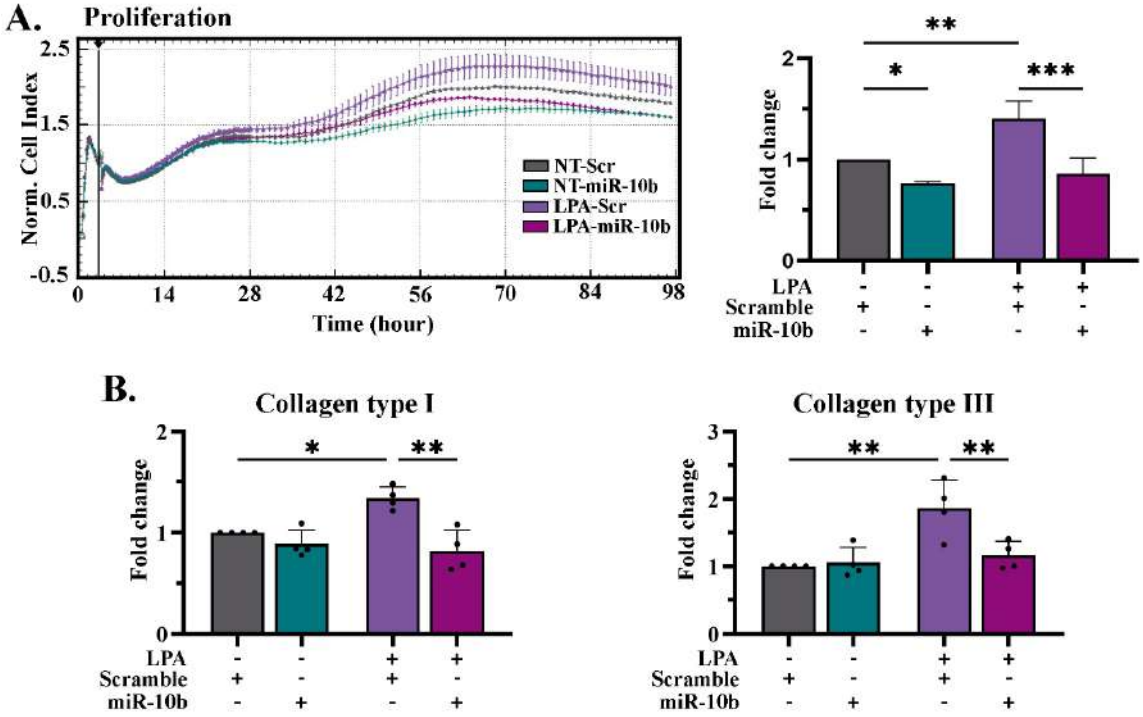

Figure 12. The role of the miR-10b/Lpar2 axis in the fibrotic process. *(A.) Cells were transfected with miR-10b or Scramble for 24 hours and subsequently exposed to the LPA2 agonist for 98 hours. The left plot shows the normalised cell index, represented as mean± SD of two or three individual wells from a representative experiment. The right graph quantifies the slope of proliferation curves from three independent experiments, describing the gradient and rate of change of the cell index curves over the 98 hours treatment period. Results are reported relative to the Scramble control for each experiment; (B.) Relative quantification of Collagen I and III genes in immortalised aged cardiac fibroblasts overexpressing miR-10b after 48 hours of treatment with the LPA2 agonist.*

Finally, we demonstrated that in vivo inhibition of miR-10b using an antagomir (Fig.13A-B) exacerbated the adverse remodelling post-MI in aged mice, leading to significant structural changes in the left ventricle (LV). Specifically, an increase in LV area and diameter was observed, along with the reduction in the anterior wall thickness in both systole and diastole. In addition, both end-diastolic and end-systolic volumes were increased is the anti-10b group (Fig.13C). These results showed that miR-10b inhibition exacerbates the adverse cardiac remodelling after myocardial infarction, manifested primarily by ventricular dilation and define the miR-10b-Lpar2 axis as a critical regulatory mechanism of fibroblast proliferation and extracellular matrix deposition in ageing, with potential for therapeutic exploitation.

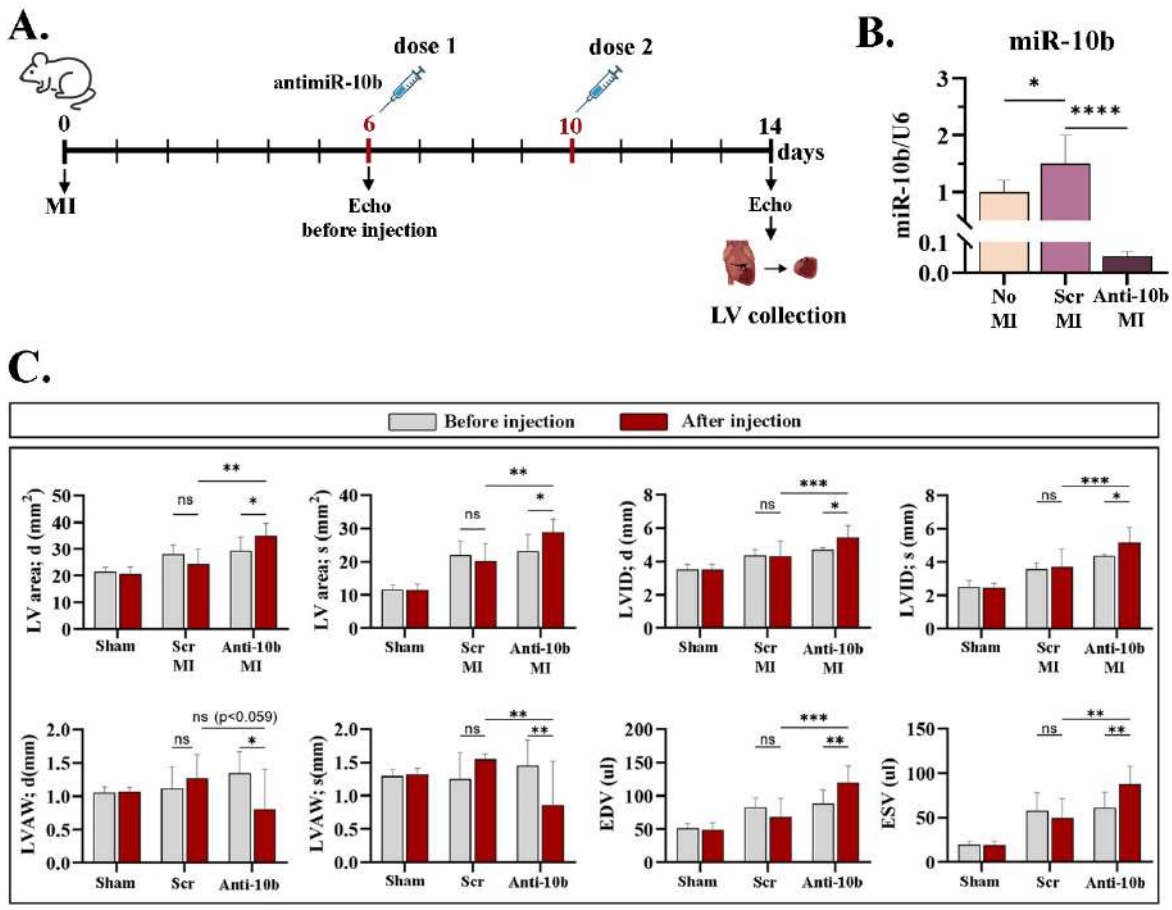

Figure 13. In vivo inhibition of miR-10b after MI. *(A.) Pictogram illustrating the experimental design. Aged C57Bl/6 mice (17-18 months) underwent either Sham or MI induction surgery. A dose of 10 mg/kg Scramble (Scr) or AntagomirR-10b (Anti-10b) was administered to the MI group after 6- and 10-days post-procedure; (B.) The expression level of miR-10b in the left ventricle after myocardial infarction; (C.) Measurements of LV area, LV internal diameter (LVID), LV anterior wall thickness (LVAW) and end-systolic (ESV)*

and end-diastolic (EDV) volumes over a cardiac cycle. Measurements were performed before the first dose of treatment and at the end point of the experiment (after injection).

Original contributions of the thesis

- Standardisation of the protocols for the isolation of adult murine, cardiac fibroblasts and cardiomyocytes for in vitro studies;
- We demonstrated that cardiac fibroblasts from aged heart has a frailty phenotype characterised by stress fibre reorganisation and metabolic changes with a shift towards glycolysis and loss of energetic flexibility under stress conditions;
- We identify and characterise the miRNAs expression profiles in cardiac fibroblasts isolated from young and old mice;
- We identify miR-29a as a globally upregulated miRNA during ageing, exerting a compensatory role with anti-fibrotic effects in this process;
- We demonstrated that miR-10b is increased in the aged male heart due to its overexpression in cardiac fibroblasts, and not in cardiomyocytes;
- We identify a temporal regulation of. miR-10b, with its expression reduced during post-MI inflammatory phase and increased during the reparative and scar maturation phase;
- We demonstrated that the exposure of cardiac fibroblasts to inflammatory stimuli, such as TNF-alpha decreased its expression, while its overexpression under the same conditions promoted cellular apoptosis;
- We demonstrated that miR-10b has an anti-fibrotic role under basal conditions in cardiac fibroblasts by reducing proliferation, migration and *Ctgf* expression;
- We demonstrated that the activation of Lpar2 receptor using an LPA2 agonist is inhibited by miR-10b overexpression in cardiac fibroblasts, leading to reduced cell proliferation and decreased expression of profibrotic genes such as Collagen I and Collagen III, thereby validating the anti-fibrotic role of miR-10b;
- We demonstrated that in vivo inhibition of after MI exacerbates fibrotic remodelling during ageing.

Introducere și obiective

Creșterea longevității a stimulat interesul oamenilor de știință pentru înțelegerea mecanismelor fundamentale care stau la baza îmbătrânirii naturale. Îmbătrânirea este un fenomen extrem de complex și insuficient înțeles, care implică un declin treptat al funcțiilor la nivel celular și la nivelul organelor, conducând la o incidență crescută a bolilor cronice. Multe modificări genetice și epigenetice, precum și dezechilibre ale proceselor biochimice, sunt strâns legate de îmbătrânire, unele dintre acestea fiind recunoscute ca semne caracteristice ale acestui proces (Gupta et al., 2014). Potrivit raportului *Word Heart Report* din 2023, deși rata mortalității standardizate în funcție de vârstă a scăzut cu o treime între anii 1990 și 2019, acestea rămân principala cauză de mortalitate în lume, numărul deceselor provocate de acestea crescând pana la 33% în ultimii 30 de ani (https://heartreport23.world-heart-federation.org/).

Modificările structurale și funcționale care apar în îmbătrânire la nivelul inimii duc în final la insuficienta cardiacă (North and Sinclair, 2012). Principalele manifestări asociate cu îmbătrânirea cardiacă sunt reprezentate de fibroză (Biernacka and Frangogiannis, 2011), inflamație cronică (Ferrucci and Fabbri, 2018), hipertrofie (Olivetti et al., 2000) și angiogeneză afectată (Lähteenvuo and Rosenzweig, 2012). Când se examinează structura și funcția inimii, atenția se îndreaptă frecvent către cardiomiocite, chiar dacă fracția de celule non-miocitară reprezintă majoritatea celulelor din inimă. Acesta fracție include diverse tipuri celulare printre care fibroblaștii cardiaci, un grup eterogen și dinamic de celule care joacă un rol esențial, atât la nivel funcțional, cât și structural, în homeostazia cardiacă, atât în condiții normale, cât și patologice. Fibroblaștii cardiaci reprezintă aproximativ 15% din numărul total de celule în miocardul șoarecelui adult, fiind distribuiți printre cardiomiocite și posedă un program molecular specific ce le permite să integreze și să răspundă rapid la semnalele extracelulare după o leziune (Tallquist and Molkentin, 2017). Activarea căilor de semnalizare fibrotice datorită stimurilor de stres din îmbătrânire determina formarea fibrozei și hipertrofiei cardiace. Acestea sunt două semne importante ale îmbătrânirii cardiace fiind strâns interconectate și declanșate reciproc. În consecință, îmbătrânirea cardiacă este asociată cu disfuncție diastolică și insuficiență cardiacă cu funcție sistolică păstrată (HFpEF), având un efect negativ asupra populației în vârstă (Singam et al., 2020).

Infarctul miocardic (IM) reprezintă unul dintre cele mai devastatoare evenimente cardiovasculare iar îmbătrânirea crește riscul de IM si, mai mult, agravează și evoluția post-

infarct, întrucât inimile vârstnicilor prezintă o angiogeneză deficitară, o rezoluție ineficientă a inflamației și o capacitate regenerativă redusă (Olivetti et al., 1991, Dai et al., 2012). O caracteristică esențială a acestei remodelări maladaptive este fibroza cardiacă, definită prin depunerea excesivă de proteine ale matricei extracelulare (MEC), în special colagen. Deși fibroza stabilizează inițial miocardul lezat, acumularea excesivă de MEC compromite complianța ventriculară, perturbă funcția electrică și, în cele din urmă, duce la apariția insuficienței cardiace (Travers et al., 2016).

Fibroblaștii cardiaci sunt principalii contribuitori la fibroza post-IM, însă ei influențează și alte aspecte ale răspunsului de vindecare, precum inflamația (Theall and Alcaide, 2022) și maturarea cicatricei (Daseke et al., 2020). Dereglarea activării fibroblaștilor cardiaci în fazele precoce după leziune duce la vindecare deficitară și la agravarea performanței cardiace (Deb and Ubil, 2014). Totuși, aceeași cicatrice fibroasă care este inițial critică pentru supraviețuire, ulterior afectează contractilitatea și contribuie la disfuncția sistolică și la insuficiența cardiacă cronică (Smolgovsky et al., 2021).

La nivel molecular, tot mai multe dovezi subliniază importanța microRNA-urilor (miRNA) în îmbătrânirea și patologia cardiovasculară. Astfel, anumite miRNA-uri au fost implicate în patogeneza infarctului miocardic și a remodelării fibrotice având roluri pro- sau anti-fibrotice (Thum et al., 2008, van Rooij et al., 2008). Descoperirea legăturii dintre miARN-uri și anumite patologii a generat un interes semnificativ pentru explorarea potențialului acestora ca nouă clasă de medicamente, iar succesul global al vaccinurilor ARNm împotriva SARS-CoV-2 a sporit interesul pentru imunoterapiile bazate pe ARN. Astfel, terapiile pe bază de ARN au devenit opțiuni reale de tratament (Seyhan, 2024).

Pe baza acestor considerente **ipoteza** de la care am plecat susține că dereglarea profilului de expresie a miRNA-urilor în îmbătrânire afectează mecanismele moleculare de menținere a homeostaziei și determină atât deteriorarea funcțională sistemică, cât și declanșarea unor procese patologice, cum ar fi fibroza cardiacă și remodelarea maladaptativă după infarctul miocardic. Astfel, **scopul** tezei a fost sa exploreze rolul miARN-urilor ca regulatori cheie ai homeostaziei celulare și ca potențiale ținte terapeutice capabile să blocheze procesele patologice, precum remodelarea matricei extracelulare și fibroza cardiacă, contribuind astfel la identificarea unor strategii inovatoare pentru promovarea îmbătrânirii sănătoase și prevenirea complicațiilor asociate vârstei. Pentru a îndeplini acest scop, activitatea mea de cercetare în perioada doctoratului a urmărit următoarele **obiective specifice**:

1. Identificarea profilului de expresie a miRNA-urilor implicate în fiziopatologia sistemului

cardiovascular în populații individuale de celule cardiace izolate de la șoareci bătrâni;

2. Evaluarea *in vitro* a efectelor miARN-urilor asociate îmbătrânirii asupra fibroblaștilor cardiaci, prin analiza impactului lor asupra fenotipului pro-fibrotic și a căilor de semnalizare implicate în îmbătrânire (inflamație și remodelare tisulară);

3. Determinarea efectul terapeutic al modularii expresiei miRNA asupra remodelării maladaptative post-IM în îmbătrânire.

Structura tezei de doctorat

Teza de doctorat este formată din două parți principale:

Partea I-Studiul actual al cunoașterii este divizată în trei capitole. **Capitolul 1** intitulat *"Rolul îmbătrânirii în apariția bolilor cardiace,,* abordează aspecte despre trăsăturile generale ale îmbătrânirii, modificările cardiace asociate cu îmbătrânirea și se concentrează în final pe informații privind remodelarea cardiacă în miocardul bătrân cu boală cardiacă ischemică. **Capitolul 2** denumit *"Fibroblastul cardiac,,* evidențiază aspecte privind fibroblastul cardiac de la trăsăturile generale până la rolul acestui tip celular în homeostazia și fibroza cardiacă. În final, **capitolul 3** se axează pe descrierea rolului *"miRNA-urilor în îmbătrânirea cardiacă și în patologii asociate îmbătrânirii,,*. Acest capitol cuprinde o analiză a literaturii de specialitate privind nomenclatura și organizarea genomică a microARN-urilor, biogeneza acestora, mecanismele de acțiune și dereglarea microARN-urilor în îmbătrânirea cardiacă și bolile cardiace asociate. În final capitolul se sfârșește cu descrierea studiilor preclinice ce vizează utilizarea miARN în terapia fibrozei cardiace.

Partea II-Contribuții originale descrie rezultatele originale corespunzătoare studiilor desfășurate pentru atingerea obiectivelor tezei. Astfel, aceasta parte este împărțită în trei capitole a căror rezultate și concluzii sunt sintetizate mai jos:

Capitolul 1- MIARN IMPLICATE ÎN BOLILE CARDIOVASCULARE: ANALIZĂ ÎN ÎMBĂTRÂNIREA NATURALĂ, cuprinde studiul intitulat *"Creșterea lui miR-29a în îmbătrânire poate fii un mecanism compensator împotriva fibrozei cardiace prin scăderea proteinei Serpinh1,,*. În acest studiu ne-am concentrat pe identificarea rolurilor a patru miRNA (miR-18a, miR-21, miR-22 și miR-29a) cunoscute a fi implicate în boli cardiovasculare în procesul de îmbătrânire cardiacă. Folosind tehnici de biologie moleculară, biochimie și culturi celulare, descrise în secțiunile „*Protocoale experimentale și metode de analiză*" am arătat că fibroza cardiacă asociată îmbătrânirii este însoțită de o creștere a

expresiei miARN-urilor miR-29a, miR-18a, miR-21a și miR-22 în inimă, dintre care miR-29a se remarcă crescut și preponderent exprimat în multiple organe prelevate de la șoareci bătrâni sugerând o semnătură moleculară comună a procesului de îmbătrânire.

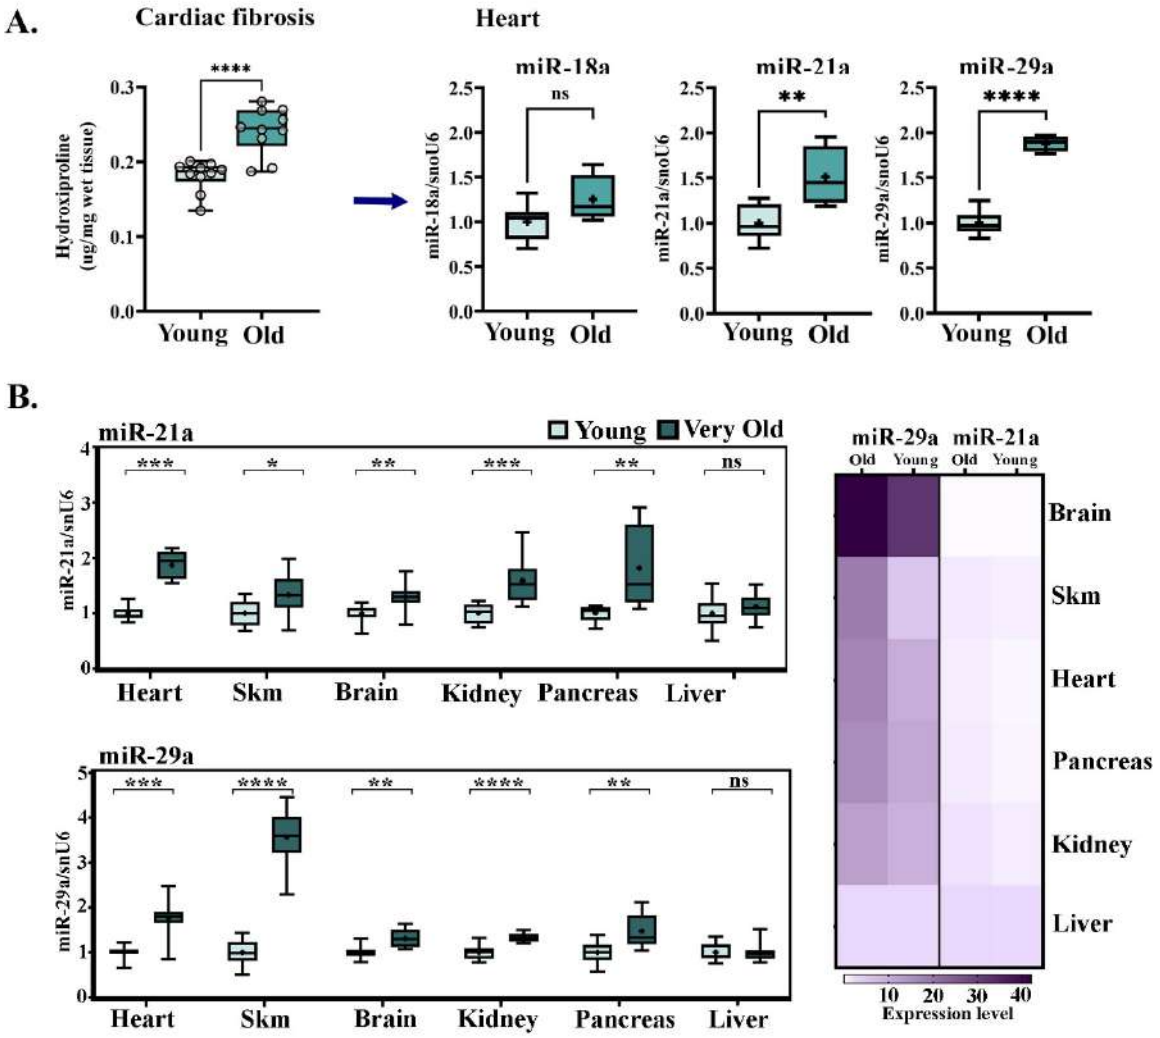

Figura 1. Investigarea profilului de expresie a miARN-urilor implicate în patologii cardiace în îmbătrânirea naturală. *(A.) Cuantificarea hidroxiprolinei și evaluarea miARN-urilor în inimi prelevate de la șoareci tineri și bătrâni; (B.) Evaluarea nivelului de expresie a lui miR-21a și miR-29a în multiple organe prelevate de la soareci tineri și batrani; Graficul de tip "heatmap" indică expresia 2^{-dCt} unde snU6 a fost utilizată ca genă de referință.*

Mai mult, prin analiza bioinformatică am identificat că miR-29a reglează în mod direct organizarea matricei extracelulare prin țintirea Serpinh1, o chaperonă esențială a colagenelor. Validările experimentale au confirmat Serpinh1 ca țintă directă a miR-29a,

expresia acestei gene fiind invers corelată cu nivelurile crescute de miR-29a în organele îmbătrânite.

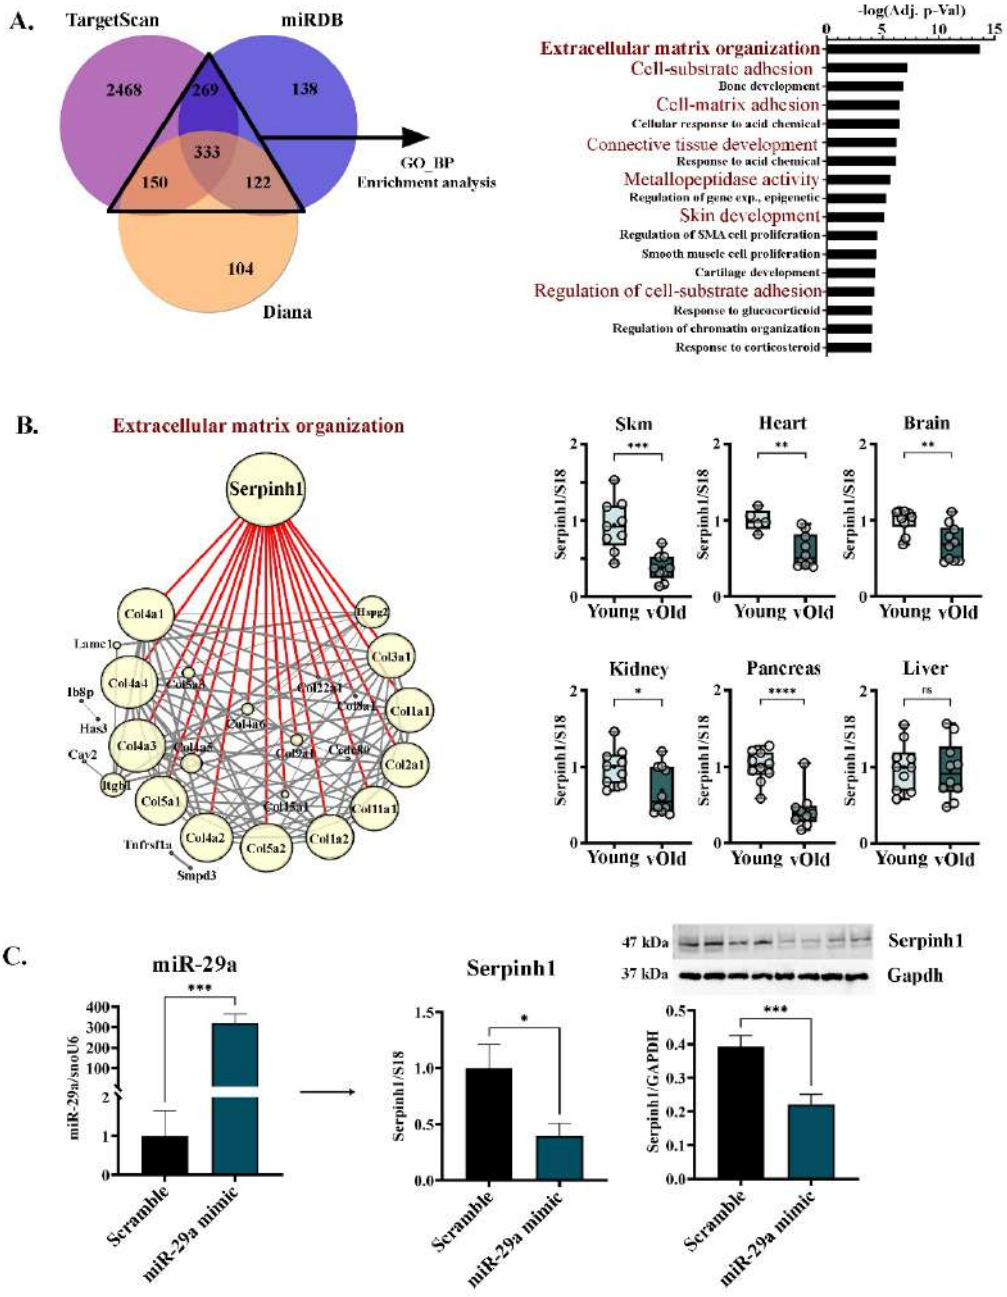

Figura 2. Identificarea Serpinh1 ca țintă al lui miR-29a. *(A.)Analiza bioinformatică de predicție a țintelor și proceselor biologice dereglate de miR-29a; (B.) Analiză PPI ce identifică Serpinh1 ca cea mai importanta proteină din ECM și validarea scăderii acesteia în multiple organe în îmbătrânire; (C.) Confirmarea in vitro a Serpinh1 ca țintă directă a lui miR-29a*

În final, studiile funcționale *in vitro* au evidențiat că supraexpresia miR-29a în fibroblaști și celule musculare cardiace inhibă proliferarea și migrarea celulară și reduce sinteza proteinelor pro-fibrotice, precum colagenul I și III, sugerând astfel că miR-29a funcționează ca un mecanism compensator anti-fibrotic, capabil să limiteze remodelarea patologică a matricei extracelular.

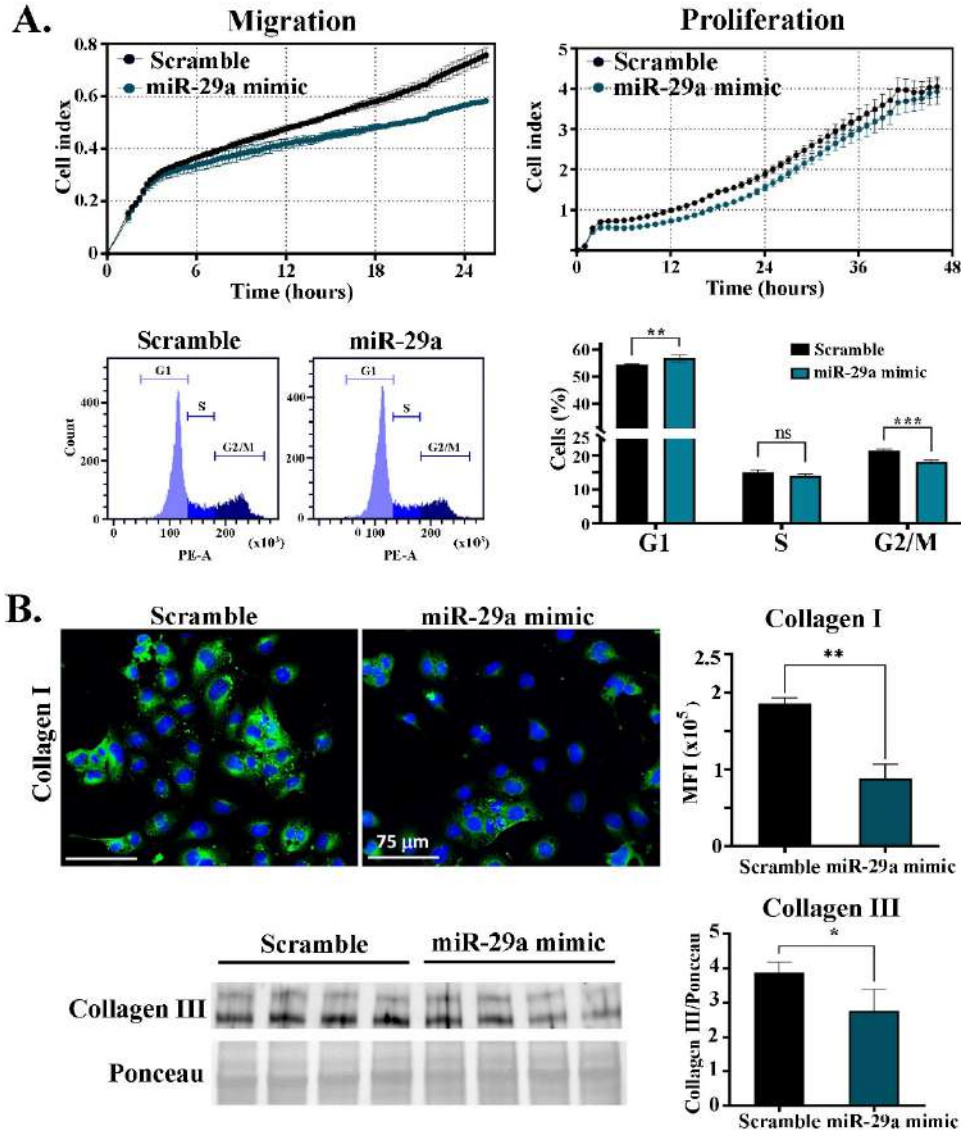

Figura 3. Rolul anti-fibrotic a lui miR-29a. *(A.) Efectul lui miR-29a asupra migrației și proliferării; (B.) Cuantificarea colagenului în celule ce supraexprimă miR-29a*

Capitolul 2- INVESTIGAREA UNOR MOLECULE DE MIARN CU EXPRESII SCĂZUTE ÎN FIBROBLAȘTII CARDIACI ÎN ÎMBĂTRÂNIREA NATURALĂ, cuprinde două studii:

Studiul 1- *"Izolarea şi caracterizarea fibroblaştilor şi cardiomiocitelor primare murine,,* a avut ca scop recuperarea unui număr maxim de celule cardiace, care să fie atât viabile, cât și funcționale. Astfel, cardiomiocitele murine adulte au fost izolate prin perfuzia retrogradă prin aorta, a tamponului de digestie ce a asigurat distribuția uniforma a enzimelor digestive prin rețeaua coronariană, ceea ce a facilitat o digestie eficientă și profundă a țesutului miocardic.

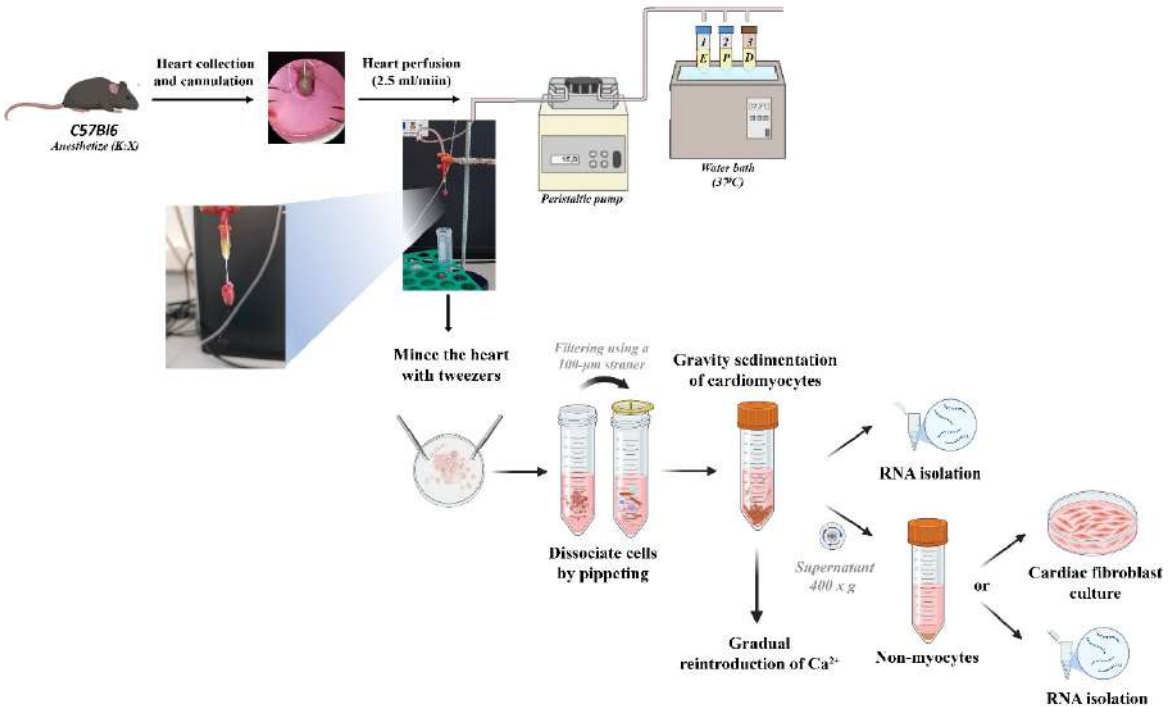

Figura 4. Etapele izolării cardiomiocitelor și celulelor non-miocitare. *Inima este fragmentată cu penseta, iar disocierea celulară este realizată prin pipetare, urmată de filtrare printr-o sită de 100 µm. Separarea cardiomiocitelor de celulele non-miocitare are loc prin sedimentare prin gravitație timp de 20 min; Supernatantul care conține celule non-miocitare este centrifugat (400 × g) pentru a obține un pelet celular, utilizat fie pentru cultura fibroblastelor cardiace, fie pentru izolarea ARN; Dacă miocitele nu sunt cultivate acestea sunt preluate pentru izolarea de RNA; În caz de cultură, cardiomiocitele sunt supuse reintroducerii graduale a calciului (0,34 mM → 0,68 mM → 1,02 mM Ca^{2+}), urmată de însămânțare timp de 1 oră pe suprafețe acoperite cu laminină și apoi menținute în cultură.*

În ceea ce privește fibroblaștii cardiaci, au fost standardizate trei protocoale, bazate pe digestii enzimatice cu enzime diferite. Comparația celor trei protocoale de izolare a dus la concluzia că protocolul bazat pe digestie fracționată a oferit cel mai bun echilibru între randament, viabilitate și puritate, permițând obținerea unor culturi stabile și reproductibile.

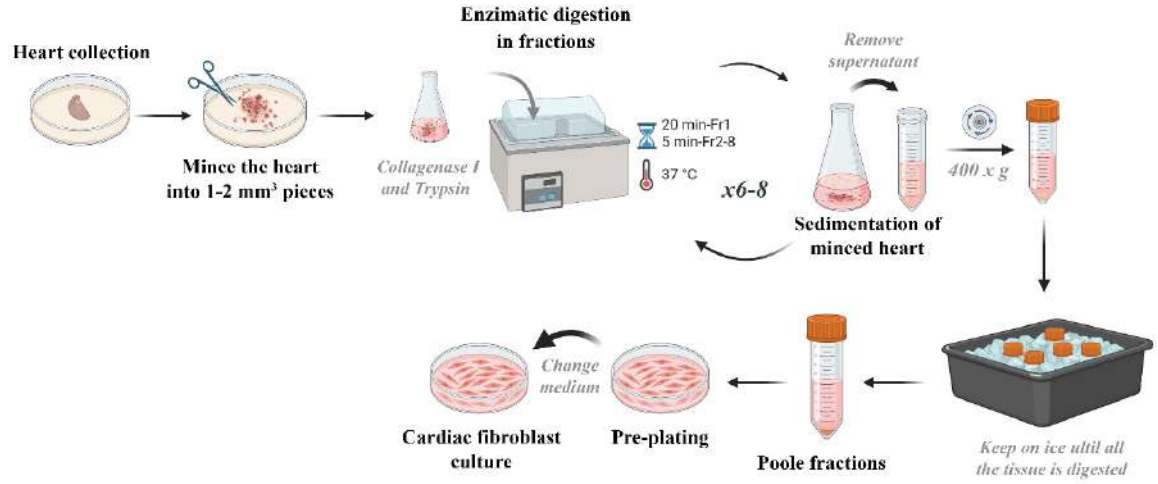

Figura 5. Etapele izolării fibroblaștilor cardiaci utilizând digestia în fracții*. După recoltare, inima este mărunțită în bucăți de 1–2 mm³, urmate de digestie enzimatică în fracții cu colagenază I și tripsină la 37°C. După fiecare rundă de digestie (20 min pentru prima fracție, 5 min pentru următoarele), supernatantul este separat, iar celulele sunt colectate prin centrifugare la 400 × g. Fracțiile obținute sunt păstrate pe gheață până la finalizarea digestiei. La final fracțiile sunt combinate iar celulele sunt însămânțate pentru pre-plating timp de 24h.*

Caracterizarea culturilor primare pure a fost realizată cu succes prin marcarea imunofluorescentă a markerilor specifici (Pdgfra, S100A4, alpha-SMA, Collagen I și Collagen III). Analiza comparativă a fibroblaștilor cardiacii izolați de la șoareci tineri și bătrâni a relevat că schimbările fenotipice asociate îmbătrânirii naturale au fost moderate, dar semnificative, la nivel celular. Astfel, fibroblaștii din animale bătrâne prezintă o ușoară creștere a dimensiunii celulare, o reorganizare a αSMA și o dependență mai mare de metabolismul glicolitic, asociată cu o capacitate redusă de adaptare la stres metabolic.

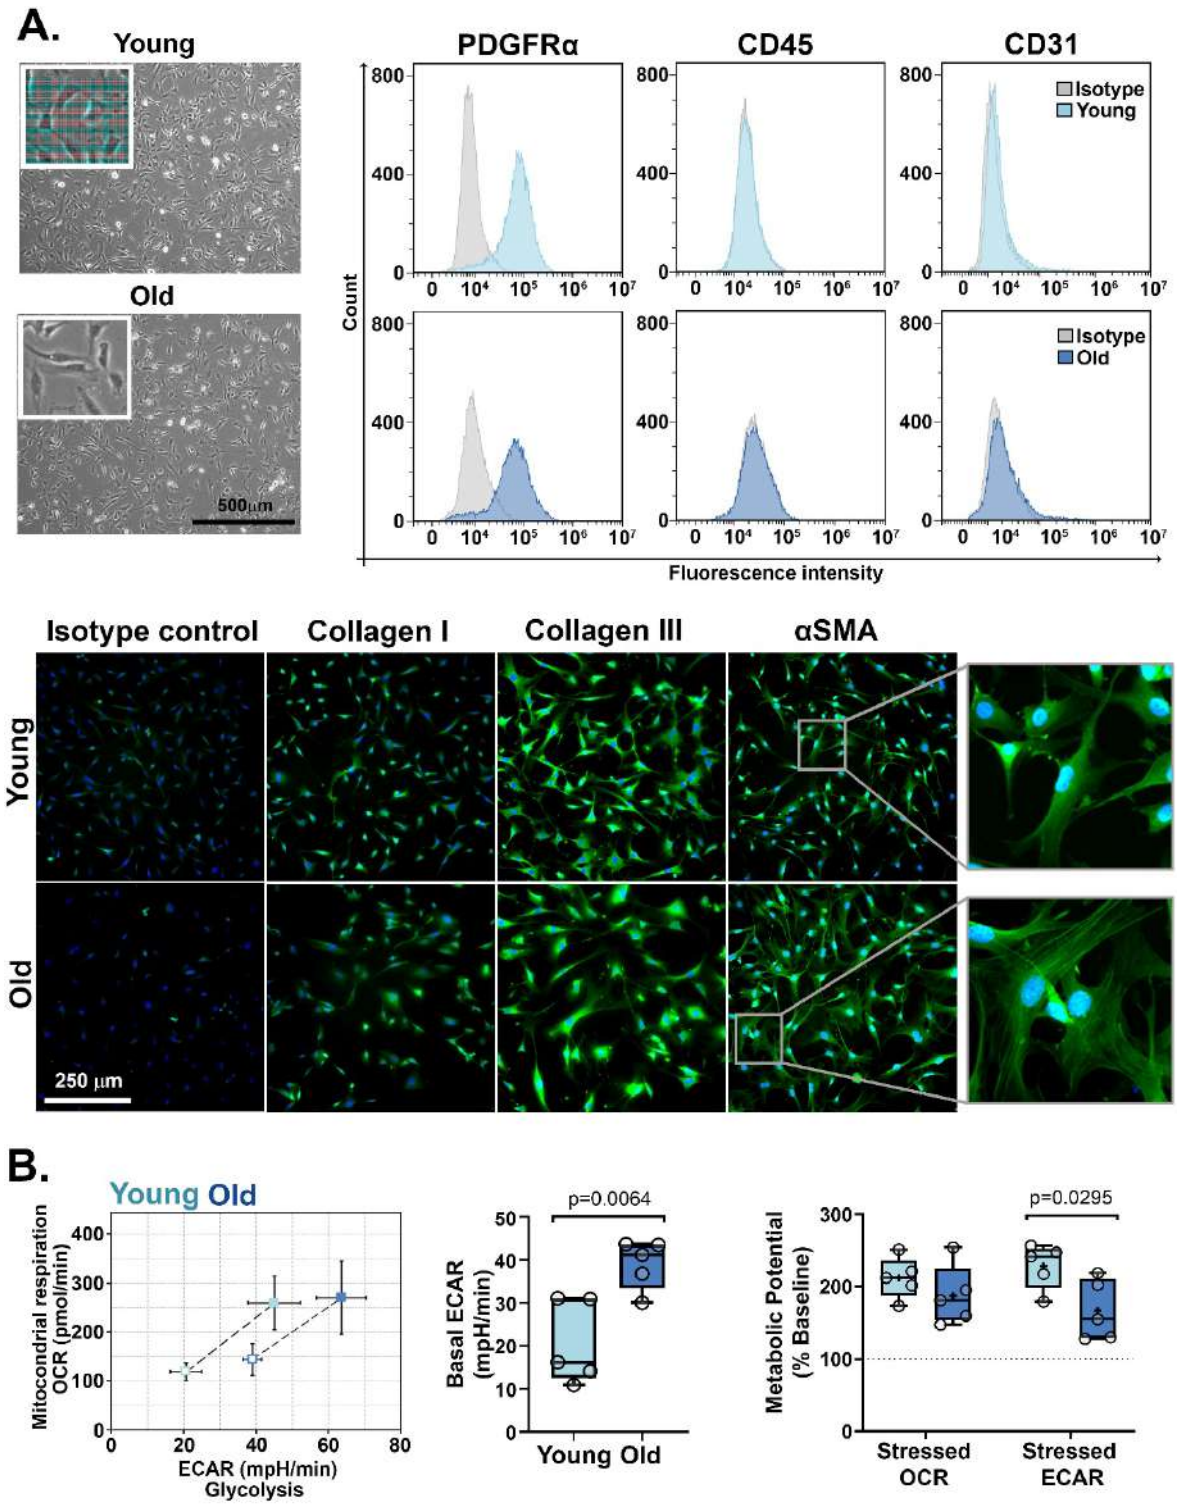

Figura 6. Diferențe ale fibroblaștilor cardiaci derivați de la șoareci tineri și bătrâni. *(A.) Caracterizarea morfologică și imunofenotipică a fibroblaștilor prin citometrie în flux și microscopie de fluorescentă a celulelor derivate de la șoareci tineri și bătrâni după 5 zile de cultură; (B.) Diferențe metabolice între fibroblasti tineri și bărăni*

(C) Imagini de microscopie fluorescentă ilustrând prezența αSMA, colagenului I și colagenului III. Se observă modele diferite de distribuție a SMA în cele două grupuri (caseta). Imaginile sunt reprezentative pentru trei experimente.

Studiul 2-*"MiARN-urile generate de locusul Meg3-Mirg sunt scăzute în timpul îmbătrânirii naturale"*. În acest studiu, am arătat că la nivelul fibroblaștilor cardiaci, îmbătrânirea naturală a fost corelată cu o modificare moderată a expresiei a 88 de miARN-uri. Dintre acestea, 68% au avut scăderi semnificative, iar aproximativ jumătate dintre acestea au avut originea în locusul Meg3-Mirg de pe cromozomul 12.

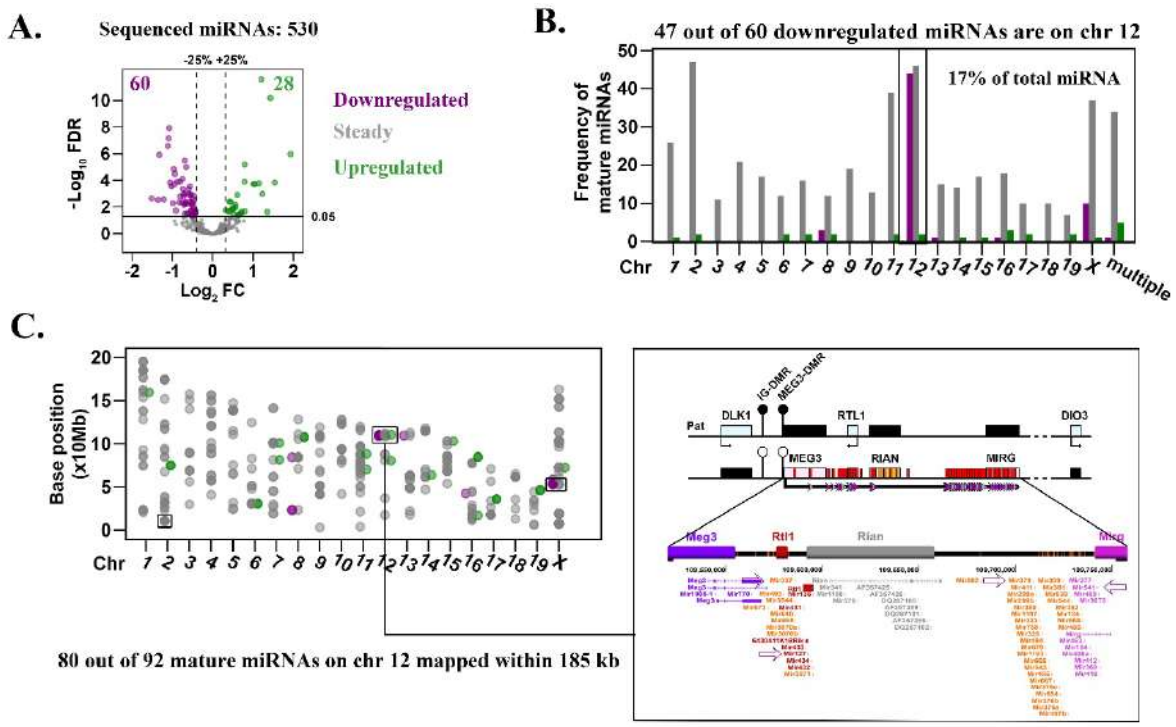

Figura 7. Identificarea miRNA-urilor în fibroblaștii cardiaci izolați de la șoareci tineri și bătrâni. *(A.) Grafic de tip volcano plot ce arată analiza miARN-urilor diferențial exprimate; (B.) Frecvența miRNA-urilor mature mapate pe fiecare cromozom al șoarecelui; (C.) Localizarea genomică a miRNA-urilor mature, reprezentată prin poziția la care începe gena corespunzătoare (miRNA-urile mature cu localizări genomice multiple nu au fost ilustrate) și reprezentarea schematică a locusului Meg3-Mirg ca parte a locusului cu imprinting patern Dlk1-Dio3. Locusul Meg3-Mirg este exprimat de pe alela maternă și conține exclusiv ARN-uri non-codante, adică lncRNA (Meg3, Rian, Mirg), snoRNA (bare portocalii) și miRNA (bare roșii). MiRNA-urile alese ca reprezentative pentru clusterul Meg3-Mirg sunt evidențiate prin săgeți.*

Astfel, îmbătrânirea naturală este asociată cu reprimarea coordonată a patru miRNA-uri reprezentative (miR-337-5p, miR-127-3p, miR-379-5p, miR-541-5p) din mega-clusterul Meg3-Mirg, fenomen observat atât în fibroblaștii cardiaci, cât și în alte organe precum mușchi scheletic, ficat și ventricule cardiace.

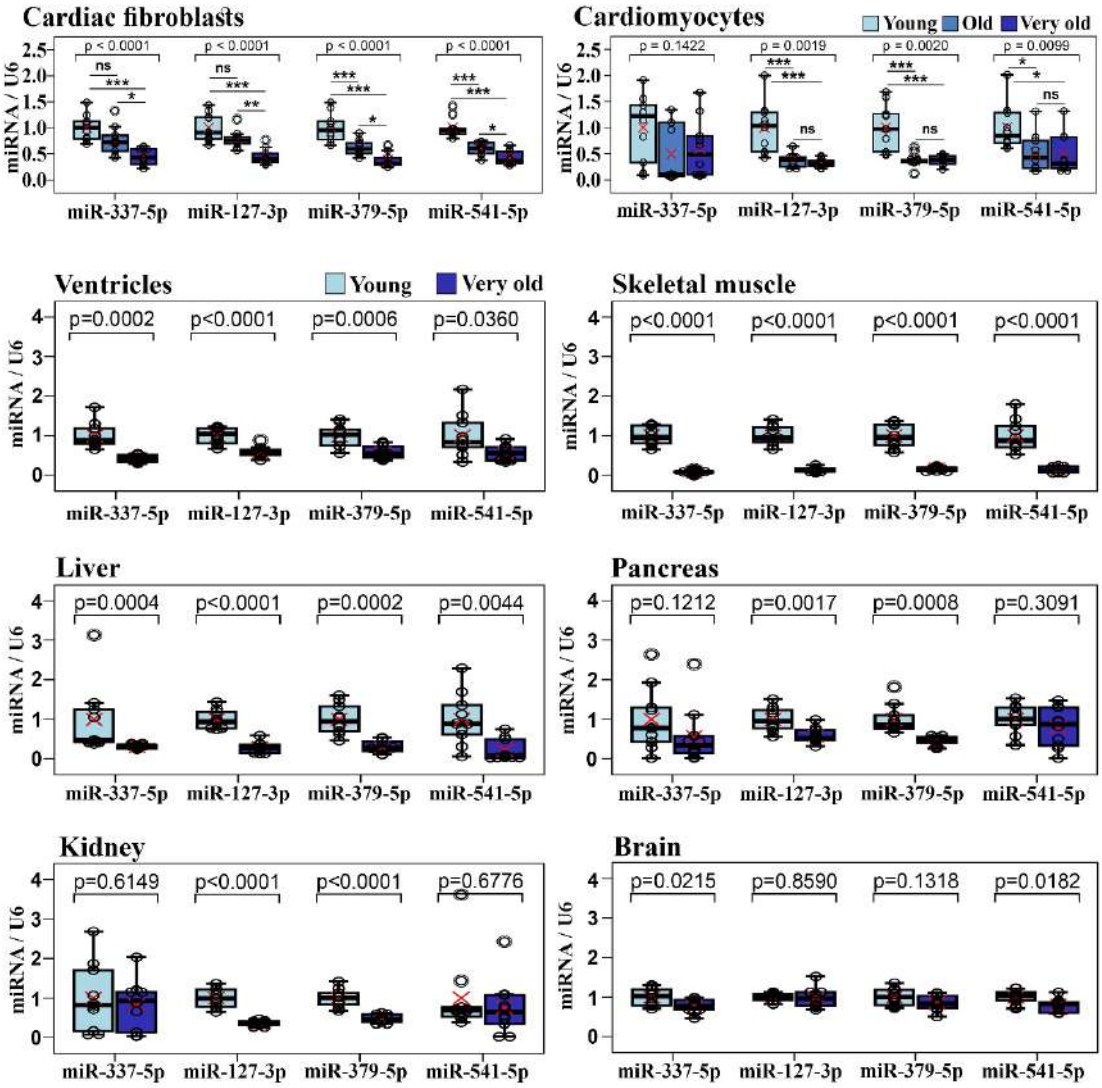

Figura 8. Analiza de RT-qPCR a celor 4 miRNA-uri reprezentative pentru locusul Meg3-Mirg în celule cardiace și multiple organe prelevate de la șoareci tineri și bătrâni.

Mai mult, țintele tuturor miARN-uri din cluster au fost semnificativ îmbogățite în căi KEGG implicate în longevitate, inflamație și fibroză, ceea ce sugerează un rol central al locusului în reglarea proceselor asociate vârstei. Acesta analiza a condus în final la identificarea Itgb2 ca genă-țintă relevantă a miARN-urilor din Meg3-Mirg, fiind supraexprimată în mai multe organe îmbătrânite (inimă, creier, rinichi, pancreas, fibroblaste cardiace).

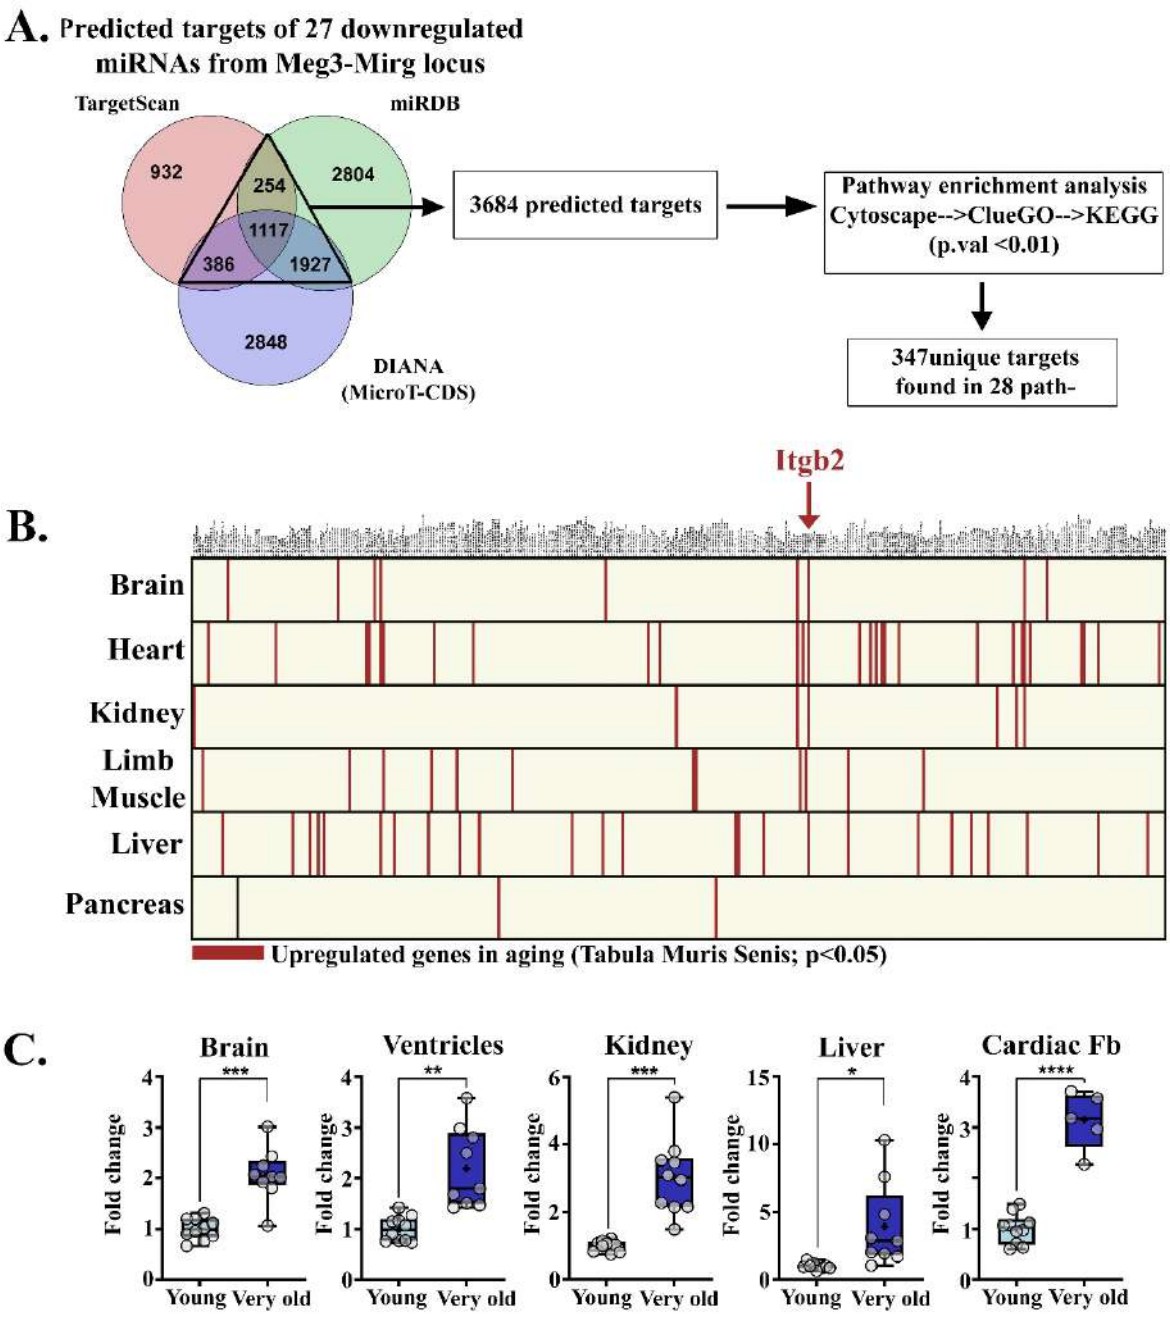

Figura 9. Gene supraexprimate în îmbătrânire care sunt țintite de miRNA-uri din locusul Meg3-Mirg. *(A.) Diagramă Venn care ilustrează țintele prezise ale celor 27 de miRNA-uri cu reglare descendentă; (B.) Ilustrație grafică a intersecției dintre genele unice găsite în calea KEGG și genele supraexprimate identificate în baza de date Tabula Muris Senis. Genele supraexprimate sunt evidențiate pentru fiecare organ.* Itgb2 *a reieșit drept singura genă supraexprimată în 4 din 6 organe; (C.) Expresia genei* Itgb2 *în creier, ventricul, rinichi, ficat și în fibroblaste cardiace cultivate*

Capitolul 3 - INVESTIGAREA UNOR MOLECULE DE MIARN CU EXPRESII CRESCUTE ÎN FIBROBLAȘTII CARDIACI ÎN ÎMBĂTRÂNIREA NATURALĂ, cuprinde studiul intitulat *"Activarea miR-10b în fibroblaștii cardiaci atenuează remodelarea adversă după infarctul miocardic în timpul îmbătrânirii prin țintirea Lpar2„*. În acest studiu ne-am axat pe identificarea rolurilor miARN-urilor crescute în fibroblaștii cardiaci în procesul de remodelare post-IM în timpul îmbătrânirii. Folosind studii funcționale *in vivo*, tehnici de biologie moleculară, biochimie, clonare și culturi celulare, descrise în secțiunile „*Protocoale experimentale și metode de analiză*", am arătat că miR-10b-5p a fost validat ca fiind supraexprimat specific în cFb izolați din șoareci masculi pe parcursul îmbătrânirii. Această creștere a fost confirmată și la nivelul inimii îmbătrânite, fiind atribuită exclusiv acumulării miR-10b în cFb și nu în cardiomiocite (CM), sugerând un rol important al acestui miARN în procesele de remodelare fibrotică asociate îmbătrânirii.

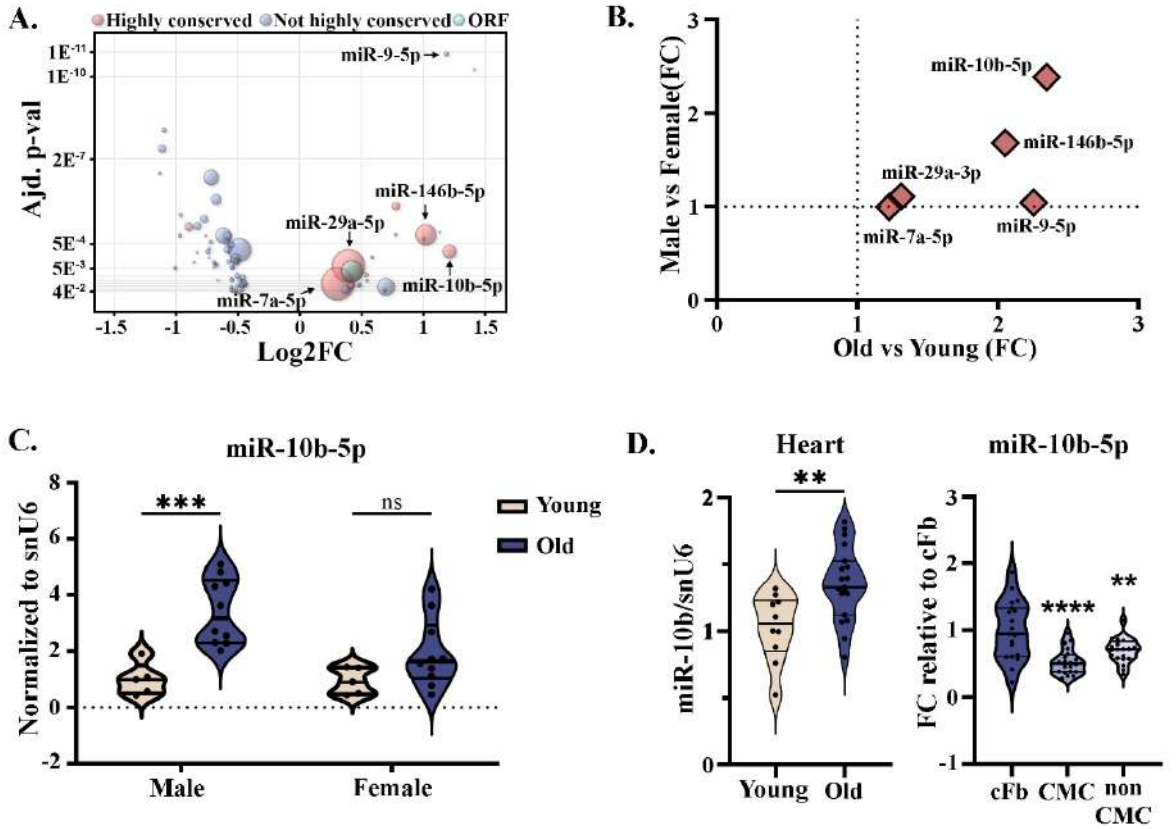

Figura 10. Dereglarea nivelului de expresie a lui miR-10b în îmbătrânirea cardiacă. *(A.) Vulcano bubble plot ce arată totalitatea miARN-urilor dereglate în fibroblaștii cardiaci în timpul îmbătrânirii. Dimensiunea bulelor reprezintă media nivelului de expresie (RPM-citiri pe milion) și culoarea reprezintă statusul de conservare: rosu= înalt conservate (conservate la vertebrate); albastru=conservate doar la mamifere; (B.) Analiza dependenței de sex a genelor supraexprimate în timpul îmbătrânirii; (C.) Validarea expresiei genice prin RT-*

qPCR a miR-10b în fibroblaștii cardiaci izolați de la animale tinere și bătrâne;(D.) Expresia relativă a miR-10b în inimi și celule cardiace izolate la șoareci tineri și bătrâni.

Datele noastre au evidențiat faptul că miR-10b a prezentat o reglare bifazică în timpul infarctului miocardic, fiind redus în faza inflamatorie și crescut în fazele de reparare/maturare ale IM. În faza acută, semnalele inflamatorii precum TNF-α inhibă expresia sa, facilitând activarea fibroblaștilor și depunerea matricei în timp ce creșterea nivelului de miR-10b promovează apoptoza fibroblaștilor și stabilizează cicatricea, prevenind acumularea excesivă de ECM.

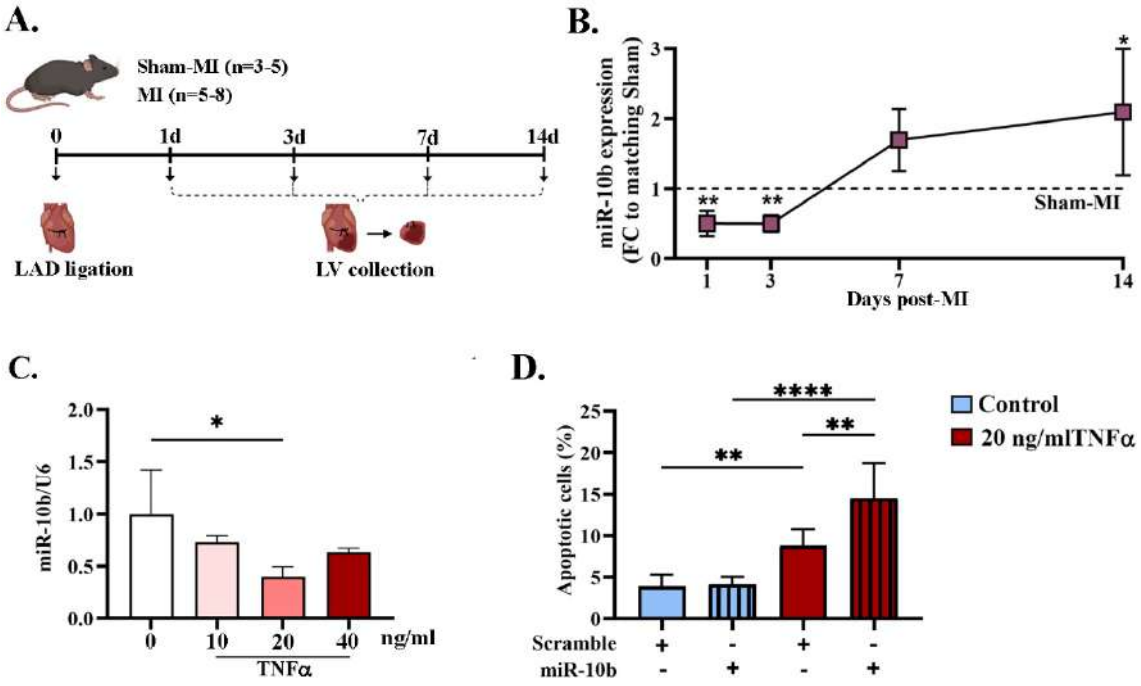

Figura 11. Expresia si rolul lui miR-10b în fazele reparatorii post-MI. *(A.) Reprezentarea schematică a designului experimental. Infarctul miocardic a fost indus la șoarecii C57Bl5 tineri (2-3 luni) prin ligatura arterei coronare descendente anterioare (LAD). Regiunea infarctată a ventriculului stâng a fost recoltată în azot lichid la 1, 3, 7 și 14 zile post-IM; (B.) Evoluția expresiei lui miR-10b la diferite intervale de timp post-MI; (C.) Expresia miR-10b în fibroblaste cardiace expuse 24h la diferite concentrații de TNFα; (D.) Impactul lui miR-10b asupra apoptozei celulare în condiții inflamatorii.*

Analiza bioinformatică și testele funcționale au identificat Lpar2 ca țintă directă a miR-10b. Supraexpresia miR-10b în fibroblaștii cardiaci bătrâni a redus nivelul Lpar2 la nivel transcripțional și proteic, iar testele cu luciferază au confirmat interacțiunea directă miR-10b-Lpar2.

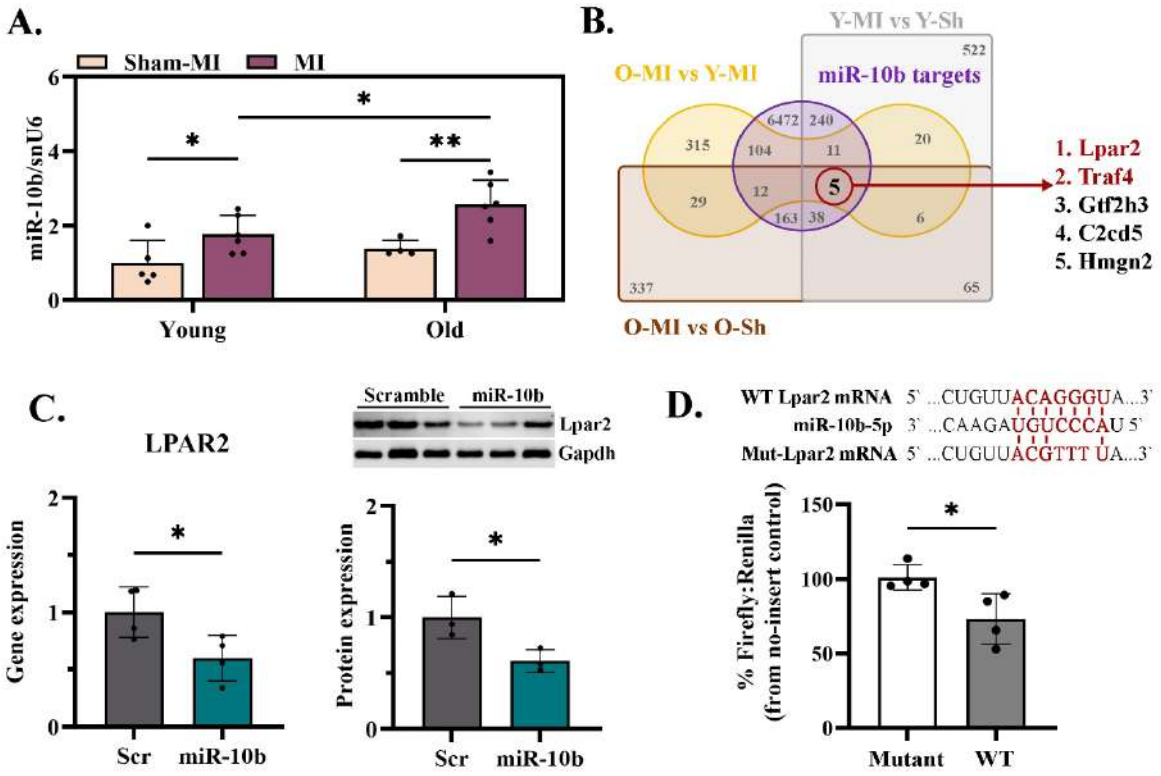

Figura 12. Identificarea și validarea Lpar2 ca țintă al lui miR-10b. *(A.) Analiza RT-qPCR a nivelului genic a lui miR-10b în fibroblaștii cardiaci izolați de la șoareci tineri și bătrâni la 7 zile post-IM; (B.) Analiza bioinformatică de identificare a genelor țintă pentru miR-10b. Genele comune identificate ca fiind scăzute în grupurile experimentale Y-MI vs Y-Sham, O-MI vs O-Sham și O-MI vs Y-MI au fost suprapuse cu țintele prezise ale miR-10b găsite în 4 baze de date; (C.) Expresia genică și proteică a lui Lpar2 în fibroblaștii cardiaci izolați din șoareci bătrâni și testul Dual-luciferase reporter care demonstrează interacțiunea directă dintre Lpar2 și miR-10b-5p.*

În plus, testele funcționale au arătat că, în prezența unui agonist specific pentru Lpar2, supraexpresia miR-10b reduce proliferarea și expresia genelor pentru colagen I/III în cFb bătrâni, consolidând rolul acestei căi de semnalizare în procesul de fibroză.

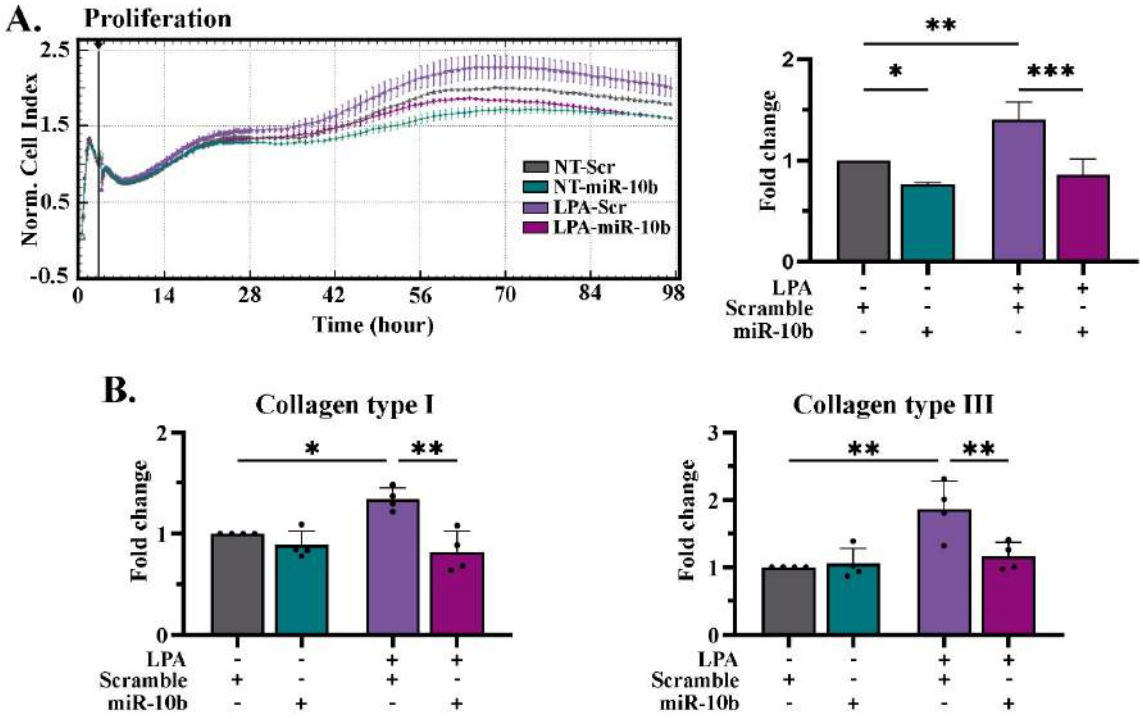

Figura 13. Rolul axei miR-10b/Lpar2 în procesul fibrotic. *(A.) Celulele au fost transfectate cu miR-10b sau Scramble timp de 24 de ore și expuse timp de 98 de ore la agonistul LPA2. Plotul din stânga ilustrează indexul celular normalizat, reprezentând media ± DS a două sau trei godeuri individuale dintr-un experiment reprezentativ. Graficul din dreapta cuantifică panta curbelor de proliferare din trei experimente separate, ce descrie gradientul și rata de modificare a curbelor indexului celular în intervalul de 98h de tratament. Rezultatele sunt raportate la controlul Scramble pentru fiecare experiment în parte; (B.) Cuantificarea relativă prin RT-qPCR a genelor Colagen I și III în fibroblasti cardiaci bătrâni imortalizați ce supraexprimă miR-10b după 48 de ore de tratament cu agoLPA2.*

În final, am demonstrat că inhibiția *in vivo* a miR-10b prin antagomir a exacerbat remodelarea adversă post-IM la șoarecii bătrâni, determinând agravarea dilatării ventriculare, a subțierii peretelui și a disfuncției cardiace. Aceste date definesc axa miR-10b–Lpar2 ca un mecanism critic de control al proliferării fibroblaștilor și al depunerii matricei extracelulare în contextul îmbătrânirii, cu potențial de a fi exploatată terapeutic.

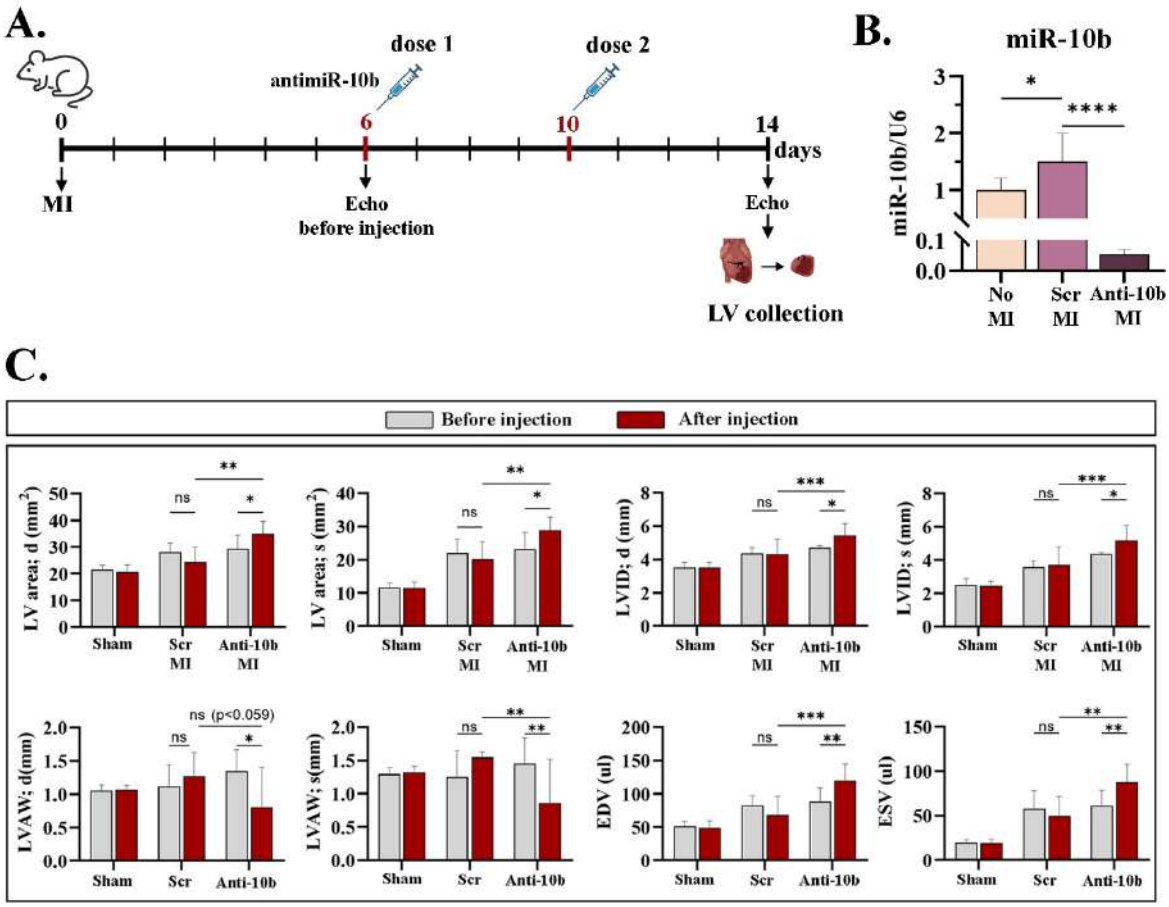

Figura 14. Studiul de inhibiție in vivo a lui miR-10b după IM. *(A.) Cronogramă ce ilustrează designul experimental. Șoareci C57Bl6 batrani (de 17-18 luni) au fost supuși intervenției chirurgicale Sham sau IM. O concentrație de 10 mg/kg Scramble (Scr) sau AntagomiR-10b (Anti-10b) a fost administrat grupului IM în ziua 6 și ziua 10 post-procedură; (B.) Nivelul de expresie a genei miR-10b în ventriculul stâng după infarctul miocardic; (C.) Cuantificarea înregistrărilor ecocardiografice într-un ciclu cardiac a ariei VS, diametrului intern al VS (LVID), peretelui anterior al VS (LVAW) și volumelor telesistolice (ESV) și telediastolice (EDV) la șoareci aflați în cohorta de studiu. Măsurătorile au fost efectuate înainte de prima doză de tratament și la sfârșitul timpului experimental (după injecție).*

Contribuțiile originale ale tezei

- Standardizarea protocoalelor pentru obținerea de fibroblaști cardiaci și cardiomiocite murine adulte pentru studii *in vitro*;
- Demonstrarea unui fenotip de fragilitate la fibroblaștii cardiaci din inimi bătrâne, caracterizat prin reorganizarea fibrelor de stres și schimbări metabolice cu preferință pentru glicoliză și pierderea flexibilității energetice în condiții de stres.
- Identificarea și caracterizarea profilul de expresie a miARN-urilor în fibroblaștii cardiaci izolați de la șoareci bătrâni și tineri.
- Identificarea miR-29a ca având un nivel crescut în mod global odată cu îmbătrânirea, modificarea sa exercitând un rol compensator, cu efecte anti-fibrotice în acest proces.
- Demonstrarea că miR-10b este crescut în inima îmbătrânită a indivizilor masculi, datorită supraexpresiei sale în fibroblaștii cardiaci și nu în cardiomiocite.
- Identificarea lui miR-10b ca fiind reglat temporal, expresia lui fiind scăzută în faza inflamatorie post-IM și crescută ulterior, în fazele de reparare și maturare a cicatricei.
- Demonstrarea că expunerea cFb la stimuli inflamatori, precum TNF-aplha, reduce expresia miR-10b, iar supraexpresia acestuia în aceleași condiții favorizează apoptoza celulară.
- Demonstrarea rolului anti-fibrotic al miR-10b în condiții normale, în cFb, cu impcat asupra scăderea proliferării, migrației și a *Ctgf*
- Identificarea si validarea Lpar2 ca țintă directă a miR-10b, atât la nivel de expresie genică, cât și proteică.
- Demonstrarea că activarea receptorului Lpar2, indusă prin expunerea la agonistul LPA2, este inhibată de supraexpresia miR-10b în cFb, ceea ce conduce la reducerea proliferării celulare și la diminuarea expresiei genelor pro-fibrotice, precum colagenul I și colagenul II. Aceste rezultate validând rolul anti-fibrotic al lui miR-10b.
- Demonstrarea ca inhibiția *in vivo* a lui miR-10b după IM duce la exacerbarea remodelării fibrotice după IM în îmbătrânire.

Introducere si obiectivele generale ale tezei de doctorat

Bolile cardiovasculare (BCV) reprezintă principala cauză de mortalitate la nivel global, cu peste 18.6 milioane de victime anual. Dintre acestea, mai mult de 80% se datorează bolii cardiace ischemice şi bolii cerebrovasculare. Deşi programele de informare a populației cu privire la factorii de risc şi prevenție se bucură de succes, incidența şi răspândirea acestor patologii sunt în continuă creștere (Roth et al., 2018). Povara bolilor cardiovasculare se resimte nu doar în calitatea vieții cetățenilor ci şi la nivel economic, având în vedere că numai în anul 2015 BCV au costat Uniunea Europeană peste 210 miliarde de euro (Elizabeth Wilkins, 2017).

Conform datelor Eurostat, în Romania aproximativ 58% dintre decesele înregistrate în anul 2016 s-au datorat BCV, cu o mai mare incidență în rândul femeilor (64.9%) decât în cazul bărbaților (51.6%). Factorul de risc medical cel mai răspândit este în prezent considerat a fi presiunea sistolică crescută, în timp ce alimentația necorespunzătoare reprezintă factorul comportamental principal asociat cu mortalitatea datorată BCV. Conform perspectivei medicale convenționale, fiziopatologia bolii ischemice cardiace este una multifactorială, având la bază disfuncția microvasculaturii coronariene, vasoconstricția severă, procese inflamatorii și/sau aterogene. Într-adevăr, deși instalarea treptată a ischemiei este favorizată de procesele tipice îmbătrânirii, atenția medicală se îndreaptă cel mai adesea către boala aterosclerotică și ocluzia arterelor coronare, aceasta culminând cu manifestarea infarctului miocardic acut (Elizabeth Wilkins, 2017; Severino et al., 2020).

Lezarea ischemică a miocardului se traduce în pierderea contractilității cardiomiocitelor și disfuncția mecanică, ducând în timp la insuficiență cardiacă. Considerând că inima are o capacitate de regenerare neglijabilă, cu un turn-over anual de doar 1-2% al cardiomiocitelor, sunt de dorit strategii care să inducă regenerarea și recuperarea funcțională a cordului (Hashimoto et al., 2018; Turner et al., 2020). Până în prezent capacitatea redusă de regenerare a cardiomiocitelor a fost abordată din multiple direcții, una dintre cele mai promițătoare căi fiind terapia celulară. Aceasta presupune administrarea directă de celule vii unui pacient, cel mai adesea prin injectare, cu scopul de a obține un efect terapeutic. Printre mecanismele benefice care pot fi declanșate cu ajutorul terapiei celulare se numără regenerarea tisulară, restabilirea unor funcții biologice compromise și creșterea capacității corpului de a combate infecții (Wang et al., 2021). Numeroase studii preclinice au consolidat potențialul terapiei celulare în procesul de recuperare miocardică post-infarct, fapt ce a

accelerat tranziția către testele clinice. Totuși, până în prezent rezultatele studiilor clinice au sugerat că grefarea ineficientă a celulelor transplantate la situsul lezat este un neajuns considerabil al terapiilor cu celule vii, acest lucru limitând în timp efectele benefice induse de celulele administrate (Fernández-Avilés et al., 2017; Pittenger et al., 2019). Din acest motiv, nevoia de a dezvolta o terapie eficientă rămâne de actualitate și reprezintă ținta multor abordări biomedicale inovative. Acestea se înscriu în sfera ingineriei tisulare și utilizează celule, biomateriale precum și arhitecturi complexe obținute prin tehnologia printării 3D. Cel mai probabil, prin progresul acestor domenii distincte se vor putea contura noi soluții pentru tratamentul afecțiunilor cardiovasculare.

Dat fiind impactul infarctului miocardic asupra populației globale, lucrarea de față și-a propus dezvoltarea unei strategii celulare pentru a facilita recuperarea cardiacă post-infarct. Ipoteza principală care a stat la baza cercetărilor a fost că administrarea simultană a două tipuri celulare, remarcate individual pentru proprietățile lor reparatoare, poate produce efecte benefice superioare mono-terapiilor.

De asemenea, în încercarea de a dezvolta pe viitor o structură 3D compatibilă cu încapsularea celulară, am optimizat formularea unui hidrogel care să poată fi aplicat ulterior în ingineria tisulară.

Structura tezei de doctorat

Lucrarea este structurată în două părți: prima dintre acestea, intitulată „Stadiul actual al cunoștințelor", descrie aspecte recente referitoare la bolile cardiovasculare, infarctul miocardic și terapia celulară, cu accent pe celulele stromale mezenchimale (MSC) și celulele formatoare de colonii endoteliale (ECFC), acestea reprezentând cele două tipuri celulare utilizate în partea experimentală. De asemenea, sunt expuse pe larg conceptele esențiale din domeniul ingineriei tisulare și al hidrogelurilor.

Cea de-a doua parte a tezei cuprinde contribuții originale și este împărțită în două studii majore.

Primul studiu, intitulat "**Terapia celulară combinată ameliorează recuperarea miocardică după infarct prin modularea reciprocă a funcțiilor MSC și ECFC**" a investigat potențialul terapeutic al celulelor mezenchimale stromale în prezența celulelor formatoare de colonii endoteliale. Acest prim studiu a avut două obiective principale:

1. Evaluarea eficienței dublului transplant MSC+ECFC comparativ cu mono-transplantul MSC in a restabili funcția cardiacă la șoarecii cu infarct miocardic indus;
2. Investigarea mecanismelor moleculare prin care ECFC modulează MSC și viceversa.

Pentru a îndeplini obiectivele acestui studiu am utilizat atât modele experimentale in vitro cât și un model animal de infarct miocardic, realizat pe șoareci. Experimentele au presupus tehnici de biochimie precum ELISA și Western blotting, tehnici de biologie moleculară precum qRT-PCR, studii pe culturi de celule și caracterizarea acestora prin citometrie în flux. Descrierea amănunțită a protocoalelor poate fi regăsită în secțiunea „Materiale și metode" aferentă acestui capitol al tezei de doctorat.

Rezultatele originale obținute în acest studiu au demonstrat că:

- Dublul transplant de MSC și ECFC îmbunătățește funcția cardiacă după infarctul miocardic, comparativ cu terapia bazată doar pe MSC;
- Terapia celulară dual (MSC+ECFC) promovează expresia Conexinei 43 și a Integrinei alpha5 în inimile infarctizate, sugerând o integrare superioară a celulelor în matricea extracelulară;
- MSC și ECFC prezintă profiluri secretorii distincte, cu efect angiogen;
- Interacțiunea cu ECFC induce în MSC expresia receptorului la fibronectină, indicând o abilitate îmbunătățită a celulelor co-transplantate de a se grefa în țesutul gazdă;
- Contactul direct între MSC și ECFC modulează activitatea lor secretoare, în special la nivelul factorilor de creștere și al citokinelor implicate în angiogeneza, în organizarea matrixului extracelular și în răspunsul inflamator.

Aceste rezultate dovedesc eficiența unei abordări duale în ceea ce privește terapia celulară a miocardului post-infarct, prin modularea reciprocă a proprietăților benefice caracteristice fiecărui tip celular utilizat. Această concluzie confirmă ipoteza inițială, anume aceea că utilizarea simultană a MSC și ECFC, recunoscute individual pentru potențialul lor reparator, are efecte benefice superioare mono-terapiei bazată pe MSC.

Datele originale, cuprinse in primul studiu al prezentei teze de doctorat, s-au concretizat in articolul intitulat „Dual Stem Cell Therapy Improves the Myocardial Recovery Post-Infarction through Reciprocal Modulation of Cell Functions", autori S. Popescu, M.B. Preda, C.I. Marinescu, M. Simionescu, A. Burlacu., publicat în revista International Journal of Molecular Sciences. 2021 May 26;22(11):5631. doi: 10.3390/ijms22115631. (Factor de impact: 5.92, Q1). Articolul a fost premiat în anul 2021 de catre UEFISCDI.

Cel de-**al doilea studiu** cuprins în secțiunea „Contribuții originale" a tezei de doctorat este intitulat „**Obținerea și testarea unei matrici citocompatibile pentru încapsulare celulară**" si a avut ca obiectiv includerea celulelor mezenchimale stromale în structura 3D a unui hidrogel foto-polimerizabil, acesta având aplicabilitate biomedicală. Acest studiu a fost efectuat în cadrul unui stagiu de cercetare Fulbright, în Departamentul de Inginerie Chimica si Biomoleculară al Universității din California, Los Angeles.

Pentru a realiza acest obiectiv am folosit metode chimice de sinteză și polimerizare a hidrogelului, teste mecanice pentru caracterizarea proprietăților acestuia precum și experimente pe culturi de celule pentru a valida cito-compatibilitatea matricei obținute. Detaliile specifice acestor experimente pot fi regăsite în secțiunea „Materiale și metode" aferentă acestui capitol al tezei de doctorat.

Rezultatele obținute în acest studiu au aratat că:

- Funcționalizarea gelatinei cu grupări metacril permite foto-polimerizarea hidrogelului într-un proces controlat din exterior și dependent de expunerea la lumină;
- Durata foto-polimerizării determină proprietățile mecanice ale hidrogelului, într-o relație de proporționalitate directă;
- Hidrogelul obținut este stabil din punct de vedere al degradării în condiții apoase;
- Foto-polimerizarea hidrogelului în contact cu pielea determină adeziunea pe aceasta, un parametru important pentru aplicabilitatea in vivo a biomaterialelor;
- Hidrogelul obținut este înalt citocompatibil iar celulele încapsulate în acesta au o viabilitate înaltă pe parcursul primelor 5 zile de încapsulare;
- Structura internă a hidrogelului permite diseminarea celulelor în interiorul acestuia, o proprietate esențială a matricilor utilizate in încapsulare celulară.

Datele originale cuprinse in acest studiu fac parte dintr-un articol în curs de publicare în colaborare.

În concluzie, rezultatele originale obținute în prezenta teză de doctorat indică o eficiență in vivo superioară a terapiei celulare duale MSC+ECFC comparativ cu mono-terapia bazată pe MSC. Mai mult decât atât, datele indică o reglare reciprocă a celor două tipuri celulare, cu

efectul ultim de stimulare a abilitații de grefare a MSC precum și a proceselor reparatoare individuale. Rezultatele obținute în cel de-al doilea studiu demonstrează versatilitatea hidrogelului foto-polimerizat și compatibilitatea acestuia cu încapsularea MSC, indicând aplicabilitatea sa biomedicală.

Aceste studii confirmă si extind potențialul uriaș al terapiilor celulare în medicina regenerativă și impactul pe care l-ar putea avea în lupta contra bolilor cardiovasculare.

Perspective

In momentul actual există o nevoie considerabilă de soluții terapeutice care să reverseze efectele dramatice ale infarctului miocardic asupra arhitecturii și funcției cardiace, încetinind astfel tranziția către insuficiența cardiacă. Cu obiectivul principal de a contribui la regenerarea cardiacă, în ultimii ani s-au înregistrat progrese semnificative atât în biomedicină cât și în domenii aparent îndepărtate.

Printr-o abordare interdisciplinară, îmi propun continuarea studiului privind terapia celulară duala MSC+ECFC și reunirea acesteia cu hidrogelul optimizat în cea de-a doua parte a tezei. Astfel, va fi posibilă testarea celulelor administrate in vivo sub forma încapsulată, ca patch, comparativ cu injecția clasică de suspensie celulară și determinarea metodei de livrare optime. De asemenea, anticipez experimente de încapsulare in vitro utilizând MSC și ECFC care să pună în evidență nu doar abilitățile secretorii ale celor două tipuri celulare, dar și capacitatea acestora de a se dispune în structuri asemănătoare țesuturilor native.

Asemenea rezultate vor putea stabili dacă administrarea celulelor într-un suport 3D protector este suficient de avantajoasă pentru a putea prelungi în timp eficiența terapiilor celulare.

Contributii personale

Lista lucrărilor publicate şi comunicate pe durata programului doctoral

Lucrare publicată într-o revistă indexată ISI – autor principal

II.1.2. Materiale şi metode 81

II.1.2.1. Izolarea MSC umane din măduva osoasă 81

II.1.2.2. Izolarea MSC umane din ţesutul adipos 82

II.1.2.3. Izolarea fibroblastelor dermale primare 83

II.1.2.4. Obţinerea fibroblastelor dermale prin diferenţierea celulelor stem pluripotente induse umane 84

II.1.2.5. Microscopia electronică de transmisie (TEM) 85

II.1.2.6. Analiza imunofenotipică prin tehnica de citometrie în flux 86

II.1.2.7. Imagistică de fluorescenţă 87

II.1.2.8. Analiza potenţialului de diferenţiere către linia adipogenă, osteogenă şi condrogenă 88

II.1.3. Rezultate 88

II.1.3.1. Obţinerea culturilor pure de MSC primare umane derivate din măduva osoasă şi din ţesutul adipos, precum şi de fibroblaste dermale umane primare 88

II.1.3.2. În cultură, MSC primare umane derivate din măduva osoasă şi din ţesutul adipos, precum şi fibroblastele dermale umane primare exprimă markerii celulari de suprafaţă specifici şi au potenţial de diferenţiere către linia adipogenică, osteogenă şi condrogenică 92

II.1.3.3. Caracterizarea fibroblastelor dermale obţinute prin diferenţierea celulelor stem pluripotente induse umane 94

II.1.4. Discuţii şi concluzii parţiale..... 98

II.2. TESTAREA *IN VITRO* A SECRETOMULUI PROVENIT DE LA O LINIE IMORTALIZATĂ DE MSC DERIVATE DIN ŢESUT ADIPOS (ADSC) URMĂRIND EFECTUL ASUPRA PROCESELOR IMPLICATE ÎN VINDECAREA RĂNILOR CUTANATE..... 99

II.2.1. Introducere şi obiective..... 99

II.2.2. Materiale şi metode..... 100

II.2.2.1. Culturi celulare..... 100

II.2.2.2. Design experimental pentru obţinerea subpopulaţiei clonale de ADSC101

II.2.2.3. Cinetica proliferării celulare..... 102

II.2.2.4. Teste de diferențiere multilinie..... 102

II.2.2.5. Cariotiparea subpopulaţiei clonale de celule imortalizate..... 103

II.2.2.6. Analiza expresiei proteice prin Western Blot..... 104

II.2.2.7. Producerea, colectarea şi păstrarea secretomului..... 104

II.2.2.8. Testarea viabilităţii celulare..... 104

II.2.2.9. Testarea proliferării celulare..... 105

II.2.2.10. Evaluarea migrării celulare prin metoda zgârierii monostratului celular („Scratch test”)..... 105

II.2.2.11. Evaluarea în timp real a chemotaxiei folosind sistemul xCELLigence... 105

II.2.2.12. Testul capacităţii de angiogeneză pe Matrigel..... 106

II.2.2.13. Detecția factorilor angiogeni utilizând kit-ul Angiogenesis Array... 106

II.2.2.14. Evaluarea re-epitelizării utilizând un model *in vitro* de cultură organotipică..... 106

II.2.2.15. Coloraţia Hematoxilină-Eozină..... 107

II.2.2.16. Analiza statistică..... 107

II.2.3. Rezultate..... 107

II.2.3.1. Caracterizarea subpopulaţiei clonale de ADSC imortalizate cu hTERT.. 107

II.2.3.2. Factorii eliberați în secretom (mediul condiționat) de către subpopulația clonală de ADSC transduse cu hTERT au o capacitate mare de a susține viabilitatea, proliferarea și migrarea keratinocitelor și a fibroblastelor dermale 110

II.2.3.3. Secretomul derivat de la subpopulația clonală de ADSC transdusă cu hTERT are proprietăți pro-angiogene.....114

II.2.3.4. Secretomul derivat de la subpopulația clonală de ADSC transdusă cu hTERT stimulează re-epitelizarea rănii realizate pe o cultură organotipică de piele 118

II.2.4. Discuții și concluzii parțiale 119

II.3. STUDIU COMPARATIV PRIVIND PROPRIETĂȚILE FIBROBLASTELOR DERMALE UMANE ŞI A MSC UMANE DERIVATE DIN MĂDUVA OSOASĂ CULTIVATE ÎN SISTEM BI- (2D) ŞI TRIDIMENSIONAL (3D) 123

II.3.1. Introducere şi obiective 123

II.3.2. Materiale şi metode 124

II.3.2.1. Celule utilizate în studiu 124

II.3.2.2. Model de cultură celulară 3D 124

II.3.2.3. Coloraţia Hematoxilină-Eozină 125

II.3.2.4. Detecţia prin imunofluorescenţă a F-actinei 125

II.3.2.5. Microscopia electronică de transmisie (TEM) 126

II.3.2.6. Coloraţia Anexină-PI 126

II.3.2.7. Analiza imunofenotipică prin tehnica de citometrie în flux 127

II.3.2.8. Analiza potențialului de diferențiere către linia adipogenă, osteogenă și condrogenă 128

II.3.2.9. Imagistică de fluorescenţă 128

II.3.2.10. Analiza expresiei proteice prin Western Blot 129

II.3.2.11. Analiza statistică 130

II.3.3. Rezultate 130

II.3.3.1. Caracterizarea comparativă a fibroblastelor dermale primare şi a MSC derivate din măduva osoasă cultivate în sistem 3D şi 2D din punct de vedere al morfologiei şi al menținerii proprietăților definitorii de MSC 130

II.3.3.2. Fibroblastele dermale primare și MSC derivate din măduva osoasă își mențin viabilitatea în culturi 3D 141

II.3.3.3. Evidențierea modificărilor de secreție a componentelor matricii extracelulare şi de exprimare a moleculelor de adeziune celulară prin cultivarea 3D a fibroblastelor dermale primare şi a MSC derivate din măduva osoasă...143

II.3.3.4. Menținerea markerilor de suprafață specifici în urma cultivării fibroblastelor dermale obținute prin diferențierea celulelor stem pluripotente induse în sistem 3D 151

II.3.4. Discuții și concluzii parțiale 153

II.4. TESTAREA *IN VITRO* A EFECTULUI SECRETOMULUI PROVENIT DE LA FIBROBLASTELE DERMALE PRIMARE ŞI DE LA FIBROBLASTELE DERIVATE

DIN CELULELE STEM PLURIPOTENTE INDUSE UMANE CULTIVATE ÎN SISTEM 2D ŞI 3D ASUPRA PROCESELOR IMPLICATE ÎN VINDECAREA RĂNILOR CUTANATE 158

CONCLUZII GENERALE 219

BIBLIOGRAFIE 220

INTRODUCERE ȘI OBIECTIVELE GENERALE

Vindecarea rănilor ţesutului cutanat este un proces fiziologic ce implică o succesiune de evenimente biologice și moleculare interconectate, ca răspuns la apariţia unei leziuni, rezultând reconstituirea integrităţii straturilor pielii şi restaurarea homeostaziei. În timpul acestui proces dinamic și complex, multiple căi biologice sunt activate și sincronizate, interacțiuni coordonate existând între celulele inflamatorii, fibroblastele (Fb) dermale, keratinocite și celulele endoteliale (Paul și Sharma, 2004; Reinke și Sorg, 2012). Totodată, celulele stem rezidente pot fi supuse auto-replicării şi diferențierii în mai multe tipuri celulare şi pot afecta implicit semnalizarea paracrină de la nivelul rănii, iar toate aceste atribute sunt cruciale pentru regenerarea tisulară (Chen și colab., 2009).

În funcție de durata procesului de vindecare, rănile cutanate sunt clasificate în acute și cronice (vindecabile și, respectiv, greu vindecabile) (Robson și colab., 2001). Rănile acute prezintă semne bine definite de recuperare în decurs de 4 până la 12 săptămâni, perioada de vindecare depinzând de amploarea leziunii. În unele cazuri, este imposibilă restabilirea în mod eficient a structurii și funcției normale a țesutului, procesul fiziologic de vindecare al rănilor fiind întrerupt, ca rezultat al disfuncționalităților în reglarea răspunsurilor de reparare tisulară, precum inflamația, angiogeneza, depunerea matricii extracelulare și recrutarea celulelor. Astfel, faza inflamatorie prelungită asociată cu o inflamație excesivă, scăderea angiogenezei, migrarea

și proliferarea slabă a keratinocitelor și Fb sunt elementele ce definesc rănile cronice (Falanga, 2005; Lazarus și colab., 1994).

În prezent, incidența rănilor cronice continuă să crească, reprezintând o provocare clinică semnificativă. De obicei, sunt afectați adulții cu comorbidități, precum ar fi insuficiența venoasă, diabetul, obezitatea, neuropatiile, insuficiența arterială sau cei care prezintă diverşi factori limitativi precum îmbătrânirea, infecțiile, alimentația deficitară, imunosupresia. Rănile cronice sunt clasificate în trei mari categorii: ulcere vasculare, ulcere diabetice și ulcere de presiune (Nunan și colab., 2014).

În ciuda eforturilor depuse de-a lungul timpului, rănile cutanate cronice și vindecarea acestora reprezintă provocări clinice majore, care implică o povară socială și medicală considerabilă. Există însă un interes semnificativ în utilizarea celulelor stem în gestionarea acestei probleme. În ultimele decenii medicina regenerativă a câştigat o atenție considerabilă, bazându-se pe refacerea, înlocuirea sau repararea celulelor, țesuturilor și organelor traumatizate, oferind astfel posibile metode de tratament.

Celulele stromale mezenchimale (MSC) joacă un rol important în acest domeniu. Acestea sunt definite drept un grup heterogen de celule progenitoare nespecializate fusiforme (formă asemănătoare cu cea a Fb), de origine mezodermică, aderente la plastic în condiţii de cultură standard şi capabile să se auto-reînnoiască prin diviziune și să se diferențieze în mai multe linii celulare (Wei și colab., 2013). Aceste celule au fost identificate pentru prima dată în măduva osoasă (BM), însă, recoltarea celulelor de la nivelul BM (aspirat provenit din BM) este o procedură invazivă şi dureroasă, cu randament scăzut de obţinere a MSC (Pittenger și colab., 1999).

Aceste limitări au condus la căutarea unor modalităţi alternative de obținere a celulelor stromale mezenchimale, precum ar fi recoltarea acestora de la nivelul ţesutului adipos sau din alte surse tisulare, ca de exemplu gelatina Wharton, sângele din cordonul ombilical, placenta, lichidul amniotic etc. (Keating, 2006; Ullah și colab., 2015; Gottipamula și colab., 2018; Eom și colab., 2011). Cu toate acestea, sunt preferate sursele care permit proceduri de recoltare minim invazive precum și izolarea unor cantități abundente de celule, cum ar fi ţesutul adipos (Kuhbier și colab., 2010).

Iniţial s-a studiat capacitatea de diferenţiere a MSC ca potenţială terapie regenerativă în vindecarea rănilor ţesutului cutanat. S-a demonstrat însă că transplantul de MSC la locul leziunii acționează în primul rând prin efecte paracrine indirecte, mai degrabă decât prin înlocuirea directă a celulelor afectate. Această acţiune paracrină este datorată secretomului constituit din factorii solubili (citokine, chemokine) şi veziculele extracelulare secretate de celule în spaţiul extracelular. Astfel, în prezent se încearcă abordarea unor noi metode terapeutice acelulare care vizează utilizarea secretomului MSC în vindecarea rănilor prin stimularea angiogenezei, modularea inflamației, reducerea formării cicatricilor și inducerea re-epitelizării (Zarei și Soleimaninejad, 2018; Guillamat-Prats, 2021; Ahangar și colab., 2020). În comparație cu utilizarea celulelor, această terapie acelulară este mai puțin imunogenă și prezintă un risc minim de formare a tumorilor (Vizoso și colab., 2017; Lu și colab., 2017; Ha și colab., 2020), oferind de asemenea şi avantaje în ceea ce privește manipularea și siguranța.

Celulele prezintă un număr limitat de multiplicări (dublări de populaţie) *in vitro,* instalându-se destul de repede senescenţa şi implicit moartea acestora. Astfel, pentru a depăși această limitare, se utilizează tehnici de reactivare a telomerazei (enzima ce contribuie la menţinerea lungimii telomerelor), celulele realizând un număr nelimitat de diviziuni sau metode de inactivare a proteinelor implicate în reglarea ciclului celular. Totodată, celulele obținute prin această metodă sunt similare sau identice din punct de vedere genetic și fenotipic cu celulele de origine. Această abordare poartă numele de ,,imortalizare celulară'' și a fost posibilă datorită cunoașterii bazelor moleculare care susțin acest fenomen *in vivo* în cazul cancerului (Ivanković și colab., 2007; Chalak și colab., 2024; de Bardet și colab., 2023).

Fb și MSC prezintă numeroase caracteristici comune: morfologia fusiformă, localizarea la nivelul țesutului conjunctiv, potenţialul proliferativ, expresia markerilor de suprafaţă specifici, multipotența, lipsa activităţii telomerazei, cât şi tiparele de expresie genică. Mai mult decât atât, acestea prezintă funcţii similare în reglarea imunității. Datorită acestor asemănări, Fb ar putea fi utilizate ca potențială alternativă a MSC pentru utilizarea în aplicații clinice care implică regenerarea țesuturilor, spre exemplu pentru tratamentul rănilor cutanate. Acestea pot fi recoltate cu ușurință în număr mare din diverse țesuturi biologice, cum ar fi pielea, țesutul adipos și gingival, în timp ce sursa cea mai frecvent utilizată de MSC, BM, oferă relativ puțin material de pornire pentru expansiunea celulară și necesită metode de recoltare invazive. În plus, timpul de dublare al populației este semnificativ mai scurt comparativ cu MSC, senescenţa Fb instalându-

se după mai mult de 50 dublări populaţionale (Huang și colab., 2010). Totodată, cerințele mediilor de cultură pentru expandarea și menținerea Fb în cultură nu sunt unele complexe.

Pe de altă parte, potențialul regenerativ al celulelor mezenchimale este influențat de diverși factori, cum ar fi țesutul de origine, vârsta donatorului, condițiile de cultură sau prezența factorilor inflamatori din organism (Ferreira și colab., 2018). Din acest motiv, mai multe strategii de precondiționare a MSC *in vitro*, precum ar fi cultivarea în condiţii hipoxice, în sistem 3D sau tratamentul cu factori inflamatori, au fost utilizate pentru a stimula proprietățile lor secretorii (Haider and Ashraf, 2010; Lu și colab., 2010). Mai mult decât atât, fibroblastelor cultivate sub formă de agregate le-a fost atribuit de către Vaheri și colab. conceptul de ,,nemoză'' (Vaheri și colab., 2009). Mai exact, această noţiune este definită ca o modalitate de activare a celulelor, care este caracterizată prin creșterea producției de COX-2 (ciclooxigenază-2), secreția de prostaglandine, proteinaze, citokine chemotactice, HGF (factorul de creștere al hepatocitelor), VEGF (factorul de creștere endotelial vascular) și exprimarea factorului nuclear activat-kappa B (Vaheri și colab., 2009; Enzerink și colab., 2010). Astfel, prin acest proces pot fi îmbunătăţite proprietăţile paracrine ale Fb, ce pot sta la baza strategiilor terapeutice care utilizează secretomul (terapii ,,fără celule'').

De asemenea, generarea de MSC din celule stem pare să ofere oportunitatea unică de a depăşi majoritatea obstacolelor care există în prezent în ceea ce priveşte utilizarea pe scară largă a MSC ca terapie inovatoare. De-a lungul timpului, s-a raportat faptul că celulele stem pluripotente induse (iPSC) pot fi diferenţiate în MSC, precum şi în Fb. Acestea provin dintr-o singură clonă de iPSC, prezentând omogenitate ridicată pentru aplicații clinice. Mai mult decât atât, performanța lor biologică este mai stabilă și mai previzibilă, întrucât tiparul molecular al MSC native se schimbă subtil între diferite loturi.

Astfel, **scopul** acestei tezei de doctorat a fost de a evalua efectele secretomului provenit de la celulele mezenchimale umane asupra procesului de vindecare a rănilor, atât *in vitro*, cât şi *in vivo* pe un model murin de rană. Pentru îndeplinirea acestui scop au fost propuse mai multe **obiective** utilizându-se surse celulare multiple, toate de origine umană.

Obiectiv 1. Obţinerea şi caracterizarea celulelor stromale mezenchimale (MSC) umane derivate din măduva osoasă și din țesutul adipos, precum și a fibroblastelor dermale umane primare sau obţinute din celule stem pluripotente induse umane.

Obiectiv 2. Testarea *in vitro* a secretomului provenit de la o linie imortalizată de MSC derivate din ţesut adipos (ADSC) urmărind efectul asupra proceselor implicate în vindecarea rănilor cutanate.

Obiectiv 3. Studiu comparativ privind proprietăţile fibroblastelor dermale umane şi a MSC umane derivate din măduva osoasă cultivate în sistem bi- (2D) şi tridimensional (3D).

Obiectiv 4. Testarea *in vitro* a efectului secretomului provenit de la fibroblastele dermale primare şi de la fibroblastele derivate din celulele stem pluripotente induse umane cultivate în sistem 2D şi 3D asupra proceselor implicate în vindecarea rănilor cutanate.

Obiectiv 5. Testarea *in vivo* a secretomului provenit de la fibroblastele dermale primare umane cultivate în sistem 2D şi 3D privind acţiunea acestuia asupra proceselor implicate în vindecarea rănilor cutanate.

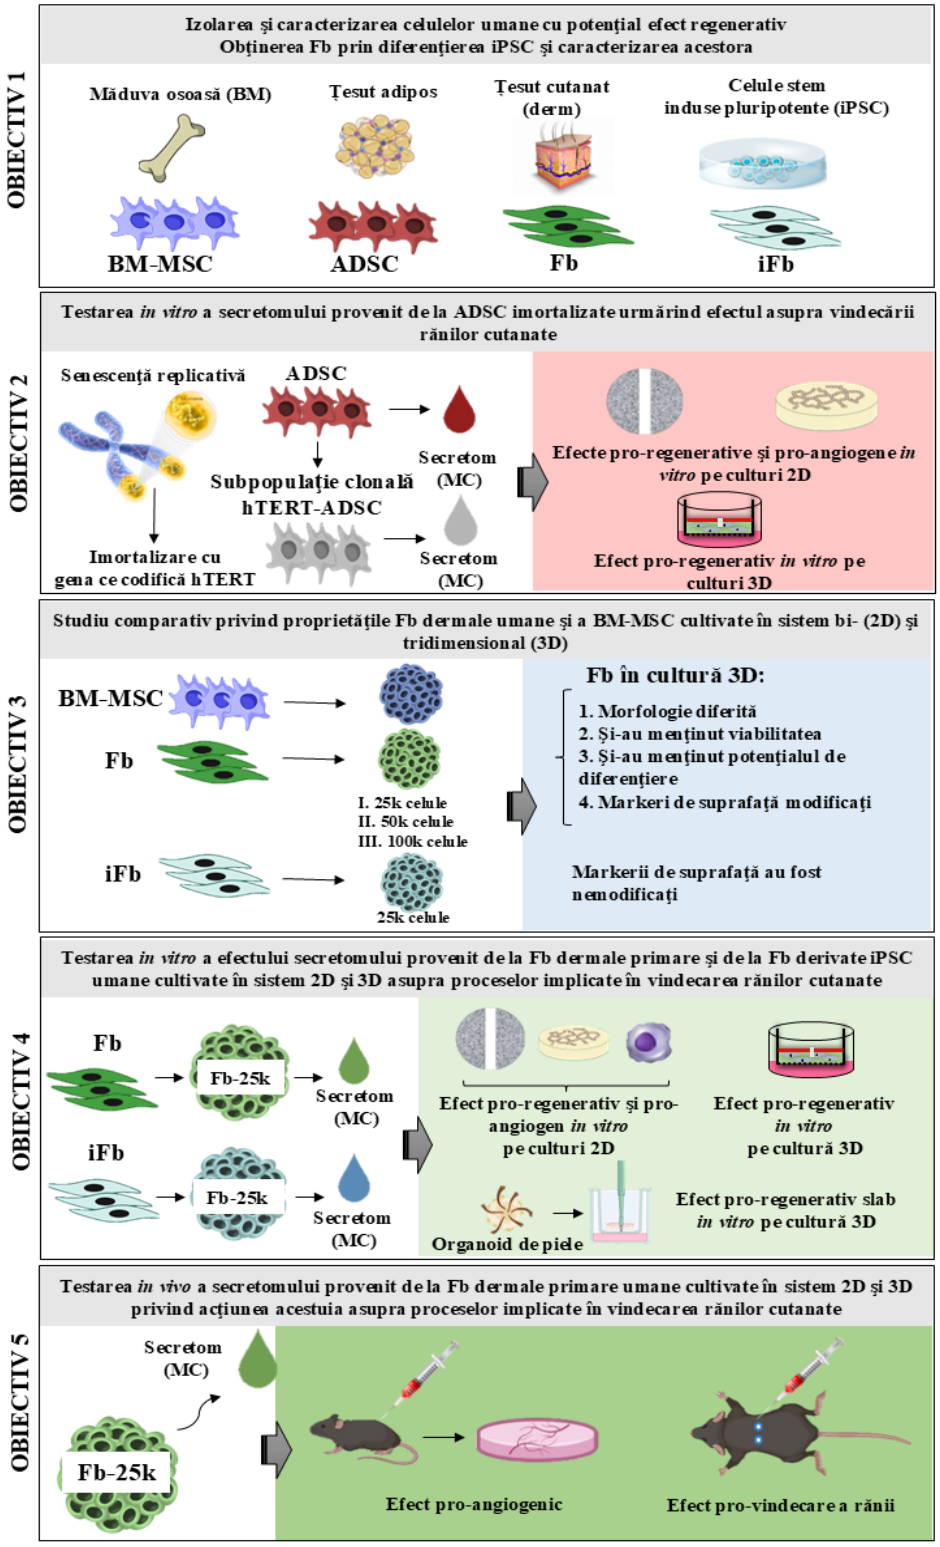
STRUCTURA TEZEI DE DOCTORAT

Teza este structurată în **9 capitole**, cuprinzând atât noţiuni teoretice privind stadiul actual al cunoştinţelor, cât şi rezultatele originale obţinute (partea de contribuţii originale).

Prima parte („Stadiul actual al cunoașterii") este structurată în ***4 capitole*** şi cuprinde date din literatură aduse la zi cu privire la subiectul vizat de această teză. Mai exact, în **capitolul I.1** este prezentată problematica rănilor cutanate, fiind vizate fundamentele anatomice şi fiziologice ale ţesutului cutanat, etapele vindecării rănilor alături de prezentarea succintă a perturbării procesului fiziologic întâlnit în cazul rănilor cronice, dar și abordările terapeutice actuale. **Capitolul I.2** vizează caracteristicile definitorii ale contribuţiei secretomului provenit de la MSC în procesul de vindecare al rănilor cutanate, punându-se accent pe caracterizarea MSC, descrierea compoziţiei secretomului provenit de la acestea, dar şi prezentarea metodelor actuale de potenţare a efectelor. De asemenea, sunt expuse studiile din literatură ce presupun utilizarea secretomului provenit de la celulele stromale mezenchimale drept potenţială terapie pentru rănile cutanate. **Capitolul I.3** se concentrează pe conceptul de utilizare a Fb ca alternativă a MSC, fiind prezentate similitudinile dintre acestea, dar şi studiile existente privind

aplicabilitatea secretomului provenit de la Fb drept posibilă terapie pentru rănile cutanate. În **Capitolul I.4** sunt prezentate potenţiale direcţii pentru obţinerea unei surse inepuizabile de celule mezenchimale: imortalizarea celulară, precum şi generarea acestora din iPSC. Unele date cuprinse în această parte fac parte dintr-un articol de tip *review* publicat anul acesta într-un jurnal indexat ISI: **Gheţu, D-.M.**, Raymond, K., Titorencu, I., Simionescu, M. **2025.** Innovative Strategies: Use of Stromal Cell-Derived Secretome for Chronic Wound Therapy. *International Journal of Molecular Sciences*, *26*(12), p.5609. 10.3390/ijms26125609 (IF/2024 = 4.9, Q1, AIS = 1.121).

A doua parte („Contribuţii originale”) este structurată în ***5 capitole*** care au avut la bază cele 5 obiective enunţate anterior. Astfel, pentru îndeplinirea obiectivelor propuse au fost utilizate tehnici precum cele de culturi celulare, citometrie în flux, biologie moleculară, histologie, precum şi teste pe animale, toate acestea fiind descrise în secţiunile „Materiale şi Metode” aferente fiecărui studiu. Conţinutul capitolelor este schematizat în figura de mai jos şi prezentat succint în cele ce urmează.



Schematizarea conținutului celor 5 capitole (obiective) cuprinse în partea a doua a tezei („Contribuții originale”). MC: mediu condiționat; hTERT: subunitatea catalitică a telomerazei umane.

Capitolul II.1 al tezei este asociat cu primul obiectiv (Obiectiv 1), fiind intitulat „**Obţinerea şi caracterizarea celulelor stromale mezenchimale (MSC) umane derivate din măduva osoasă și din țesutul adipos, precum și a fibroblastelor dermale umane primare sau obţinute din celule stem pluripotente induse umane**”. Acesta prezintă obţinerea de celule primare cu potențial regenerativ pentru vindecarea rănilor (MSC derivate din BM şi ţesut adipos şi Fb izolate de la nivelul dermului) şi caracterizarea acestora din punct de vedere al markerilor specifici şi al capacităţii de diferenţiere către liniile celulare mezodermice: linia adipogenă, osteogenă şi condrogenă. Mai mult decât atât, acesta este axat şi pe obţinerea Fb prin diferenţierea din iPSC şi caracterizarea acestora din punct de vedere al markerilor de suprafaţă şi intracelulari specifici (precum vimentina şi colagenul). Descrierea amănunțită a protocoalelor poate fi regăsită în secțiunea „Materiale și metode” aferentă acestui capitol. Rezultatele arată succesul izolării de celule primare care exprimă markerii specifici şi deţin capacitatea de diferenţiere către liniile celulare mezodermice. De asemenea, au fost obţinute Fb prin diferenţierea iPSC (iFb), exprimând markerii de suprafaţă şi intracelulari specifici. Aceste celule au fost folosite în experimentele *in vitro* şi *in vivo* pentru îndeplinirea celorlalte obiective propuse, care au ca scop utilizarea secretomului (mediului condiţionat) drept terapie „acelulară” pentru rănile cutanate.

Capitolul II.2 (Obiectiv 2) este intitulat „**Testarea *in vitro* a secretomului provenit de la o linie imortalizată de MSC derivate din ţesut adipos (ADSC) urmărind efectul asupra proceselor implicate în vindecarea rănilor cutanate**”. În cadrul acestuia este prezentată generarea unei linii imortalizate de ADSC (subpopulaţie clonală) prin transducția lentivirală a genei care codifică transcriptaza inversă (componenta catalitică) a telomerazei umane (hTERT) pentru inhibarea fenomenului de senescenţă replicativă şi evaluarea *in vitro* a efectelor secretomului (mediului condiţionat) provenit de la aceste celule asupra proceselor cheie asociate vindecării rănilor cutanate. Pe scurt, s-a raportat impactul secretomului (mediului condiţionat) asupra proliferării și migrării keratinocitelor, Fb şi celulelor endoteliale, cât și asupra angiogenezei (procese care au loc în timpul fazei proliferative a vindecării rănilor). Totodată a fost demonstrat şi efectul de susținere a procesului de re-epitelizare a unei răni realizate pe un model de cultură organotipică de piele umană. Rezultatele expuse în acest capitol au fost cuprinse într-o lucrare publicată într-un jurnal indexat ISI: **Iacomi, D. M.**, Roşca A. M., Ţuţuianu, R., Neagu, T. P., Prună, V., Simionescu, M., Titorencu, I. **2022**. Generation of an

immortalized human adipose-derived mesenchymal stromal cell line suitable for wound healing therapy. *International Journal of Molecular Sciences*, 23(16):8925. DOI: 10.3390/ijms23168925 (IF/2022 = 5.6, Q1, AIS = 1.028).

Capitolul II.3 (Obiectiv 3) intitulat „**Studiu comparativ privind proprietăţile fibroblastelor dermale umane şi a MSC umane derivate din măduva osoasă cultivate în sistem bi- (2D) şi tridimensional (3D)**" a implicat analiza comparativă a BM-MSC şi a Fb dermale primare umane (ca sursă celulară alternativă mult mai accesibilă)/diferenţiate din iPSC cultivate în sistem 3D (drept strategie de îmbunătăţire a capacităţii secretorii), mai exact în agregate celulare (sferoizi) obţinute prin cultivarea suspensiei celulare în picături suspendate („*hanging drops*"). Sferoizii/celulele primare din componenţa acestora au fost analizaţi/analizate din punct de vedere al morfologiei, viabilităţii, secreţiei componentelor matricei extracelulare, prezenţei moleculelor de adeziune, dar şi de menţinere al markerilor de suprafaţă specifici şi a potenţialului de diferenţiere către linia adipogenă, osteogenă şi condrogenă. Rezultatele au arătat că ambele tipuri celulare primare prezintă capacitatea de a agrega în sferoizi după 72 de ore, fiind detectată secreţia elementelor matricii extracelulare, menţinerea potenţialului de diferenţiere, însă şi unele modificări morfologice şi de prezenţă a markerilor de suprafaţă specifici. Din punct de vedere al viabilităţii nu s-au remarcat modificări semnificative în urma procesului de agregare. Fb diferenţiate din iPSC au format de asemenea sferoizi, menţinându-şi markerii de suprafaţă specifici în urma agregării. Datele originale cuprinse în acest studiu fac parte dintr-un articol în curs de redactare.

În **capitolul II.4** (Obiectiv 4) - „**Testarea *in vitro* a efectului secretomului provenit de la fibroblastele dermale primare şi de la fibroblastele derivate din celulele stem pluripotente induse umane cultivate în sistem 2D şi 3D asupra proceselor implicate în vindecarea rănilor cutanate**" – sunt prezentate rezultatele obţinute *in vitro* privind evaluarea efectelor secretomului (mediului condiţionat) provenit de la Fb dermale primare cultivate în sistem 3D (sferoizi) asupra proceselor cheie asociate vindecării rănilor cutanate: inflamaţia, angiogeneza şi re-epitelizarea, comparativ cu efectele mediului condiţionat provenit de la Fb cultivate în monostrat (2D). S-a arătat creşterea secreţiei factorilor pro-angiogenici prin cultivarea tridimensională (3D) a Fb dermale umane primare sub formă de sferoizi (25000 celule/sferoid – 25k), îmbunătăţirea proceselor de migrare şi proliferare, cât şi de re-epitelizare la nivelul rănii pe un model 3D de cultură organotipică de piele în prezenţa mediului condiţionat

provenit de la aceste celule. Astfel, rezultatele obţinute confirmă faptul că secretomul provenit de la aceste celule cultivate în sistem 3D reprezintă astfel o posibilă strategie de tratament pentru vindecarea rănilor. Totodată, sunt prezentate şi rezultatele privind evaluarea secretomului obţinut de la Fb derivate din iPSC (iFb) cultivate atât în sistem 2D cât şi 3D (25000 celule/sferoid), însă nefiind evidenţiat un efect de potenţare a re-epitelizării pe un model 3D al unui echivalent de piele obţinut din organoizi. Datele originale cuprinse în acest studiu fac parte dintr-un articol în curs de redactare.

Ultimul capitol al părţii originale, **capitolul II.5** (Obiectiv 5) **-** „**Testarea *in vivo* a secretomului provenit de la fibroblastele dermale primare umane cultivate în sistem 2D şi 3D privind acţiunea acestuia asupra proceselor implicate în vindecarea rănilor cutanate**" este asociat cu evaluarea *in vivo* a efectelor secretomului (mediului condiţionat) provenit de la Fb dermale primare cultivate în sistem 3D (sferoizi alcătuiţi din 25000 celule/25k) din punct de vedere al angiogenezei şi al procesului de re-epitelizare, comparativ cu efectele mediului condiţionat provenit de la Fb cultivate în monostrat. Pe scurt, rezultatele au arătat efectul benefic al secretomului provenit de la Fb dermale umane primare asupra angiogenezei şi a re-epitelizării rănilor cutanate, utilizându-se tehnica Matrigel *plug assay* şi un model de rană la şoareci. Datele originale cuprinse în acest studiu fac de asemenea parte dintr-un articol în curs de redactare.

Conţinutul tezei se încheie cu referințele bibliografice aferente.

Brevete naționale înregistrate

1. Aplicaţie OSIM nr. A/00370 (25.06.2021): „Hidrogeluri polimerice compozite cu proprietăţi antibacteriene şi cicatrizante şi procedeu de obţinere a acestora"; Autori: Simionescu M., Roşca A.M., Titorencu I.D., **Iacomi M.D.**, Ţuţuianu R., Prună V., Lasca I., Chercheriţă I.A., Neagu P.T., Mogoantă L., Mogoşanu G.D., Pirici N.D., Streba C.T., Birca A.C., Burduşel A.C., Stoica A.E., Grumezescu A.L., Chircov C.

CURSURI ŞI SEMINARII EFECTUATE PE DURATA PROGRAMULUI DOCTORAL

1. Training School (Școala de formare) "3D Skin Cultures" organizată în cadrul acțiunii COST CA21108 – Rețeaua Europeană pentru Ingineria și Modelarea Pielii (NETSKINMODELS) – 29 iunie-2 iulie 2025, Nijmegen, Țările de Jos.

2. Prof. Dimitris Kardassis: Lectures to the students (Lipoprotein pathways and their roles in the pathophysiology of atherosclerosis; Transcriptional Regulation of Cardiovascular Genes: Basic principles and methodologies *in vitro* and *in vivo*; Hormone Nuclear receptors: from basic

biology to clinical exploitation in cardiovascular disease), 14-18 noiembrie 2024, Institutul de Biologie şi Patologie Celulară ,,Nicolae Simionescu'', Bucureşti, România.

3. Curs de formare realizat la Universitatea de Medicină şi Farmacie ,,Carol Davila'' din Bucureşti intitulat ,,*Ştiinţa animalelor de laborator"* în perioada 30.01-10.02.2023.

4. INTERA-1 Summer School ,,*Encapsulation of cells and drugs: materials, procedures and applications"*, 13-14 mai 2021, Institutul de Biologie şi Patologie Celulară ,,Nicolae Simionescu'', Bucureşti, România.

5. INTERA Online Workshop ,,*Recent advances in the field of obtaining nanovectors for gene transfection*'', 22 aprilie 2021, Institutul de Biologie şi Patologie Celulară ,,Nicolae Simionescu'', Bucureşti, România.

6. THERAVALDIS Online Workshop ,,*Diabetes in cardiovascular diseases; pathogenic mechanisms and targeted therapies*'', 27 noiembrie 2020, Institutul de Biologie şi Patologie Celulară ,,Nicolae Simionescu'', Bucureşti, România.

7. DIABETER Online Workshop *,,A new therapeutic tool in autoimmune diabetes: Mesenchymal Stromal Cell"*, 20 noiembrie 2020, Institutul de Biologie şi Patologie Celulară ,,Nicolae Simionescu'', Bucureşti, România.

STAGII INTERNAŢIONALE

1. Stagiu internaţional cu o durată de 9 luni (1.09.2023-31.05.2024) realizat la Centrul Medical al Universităţii din Leiden, Ţările de Jos, beneficiind de o bursă acordată de Ministerul Educației din România (conform HG 118/2023).

PREMII

1. Premiul oferit de Ministerul Educației și Cercetării și UEFISCDI ,,Realizări științifice – Articol original '', PN IV, Program 5.2 - Resurse umane – Subprogram 5.2.3 – Suport – Lista 1 – Primele aplicaţii trimise pentru articolele din 2021 şi 2022_13.03.2023 pentru articolul ,,Generation of an immortalized human adipose-derived mesenchymal stromal cell line suitable for wound healing therapy'' publicat în revista ,,International Journal of Molecular Sciences'', Volumul 23 (16), 8925, având factorul de impact în 2022 = 5.6 (**Iacomi, D. M.**, Roşca, A. M., Ţuţuianu, R., Neagu, T. P., Prună, V., Simionescu, M., Titorencu, I.).

2. Premiul oferit de Ministerul Educației și Cercetării și UEFISCDI „Realizări științifice – Articol original ”, Subprogramul 1.1 - Resurse umane - Acordarea rezultatelor cercetării - Articole, Concurență 2021, Rezultatele evaluării_Lista 2 - Cereri de premiere depuse pentru articolele publicate în 2021_18.11.2021 - pentru articolul „Human mesenchymal stromal cell-derived exosomes promote in vitro wound healing by modulating the biological properties of skin keratinocytes and fibroblasts and stimulating angiogenesis” publicat în revista „International Journal of Molecular Sciences”, Volumul 22(12), 6239, 2021, având factorul de impact în 2021 = 5.924 (Ţuţuianu, R., Roşca, A. M., **Iacomi, D. M.**, Simionescu, M., Titorencu, I.).

BURSE OBȚINUTE PE DURATA PROGRAMULUI DOCTORAL ȘI FINANŢAREA CERCETĂRILOR

BURSE

1. Bursă acordată de către Ministerul Educaţiei pentru realizarea unui stagiu de cercetare în străinătate (conform HG 118/2023) la Centrul Medical al Universităţii din Leiden, Ţările de Jos cu durată de 9 luni (1.09.2023-31.05.2024).
2. Bursă de doctorat - Şcoala de Studii Avansate a Academiei Române (2020-2023).

COLABORĂRI ÎN PROIECTE DE CERCETARE

Colaborator în granturi naționale:

1. **PN-IV-P7-7.1-PED-2024-1446**

Proiect experimental demonstrativ

Titlul proiectului**:** Substituenţi inovativi cu structură tridimensională şi activitate antimicrobiană pe bază de colagen pentru reconstrucţia cranio-facială (*Innovative antimicrobial collagen based three dimensional scaffolds for craniofacial reconstruction*)

Perioada: 2025-2027

Coordonator: Institutul de Biologie şi Patologie Celulară „Nicolae Simionescu”, Bucureşti

Director de proiect: Dr. Irina Titorencu

Partener: LMS PLASTIC SURGERY CLINIQUE SRL – Dr. Ana Căruntu

2. **PN-III-P1-1.1-TE-2021-1344**

Proiect de cercetare pentru stimularea constituirii de tinere echipe de cercetare independente

Titlul proiectului: Îmbunătățirea proprietăților paracrine ale fibroblastelor prin agregare tridimensională pentru terapia rănilor cronice *(Enhancing the paracrine properties of fibroblasts by three-dimensional aggregation for chronic wounds therapy)* - FIBROTHER

Perioada: 2022-2024

Director de proiect: Dr. Roşca Ana-Maria

3. **PN-III-P2-2.1-PED-2021-4275**

Proiect experimental demonstrativ

Titlul proiectului: Optimizarea interacţiunii celulelor stem mezenchimale umane cu structuri biomimetice inovative cu aplicabilitate în ingineria tisulară *(Optimization of human mesenchymal stem cells interaction with innovative biomimetic structures for tissue engineering applications)* - BioMimCells

Perioada: 2022-2024

Coordonator: Universitatea Politehnica Bucureşti

Director de proiect: Dr. ing. Diana Maria Vrânceanu

Parteneri:

Institutul de Biologie şi Patologie Celulară „Nicolae Simionescu”, Bucureşti - Responsabil partener: Dr. Irina Titorencu

Institutul National de Cercetare şi Dezvoltare în Optoelectronică (INOE 2000) - Responsabil partener: Dr. Alina Vlădescu

4. **PN III PCCDI 45/2018**

Proiecte complexe realizate în consorţii Cercetare Dezvoltare Inovare

Titlul proiectului: Nanostructuri bioactive pentru strategii terapeutice inovatoare (*Bioactive Nanostructures for Innovative Therapeutic Strategies*) - NANOLIFE

Perioada: 2018-2020

Coordonator: Universitatea de Medinică şi Farmacie din Craiova

Director de proiect: Dr. Laurenţiu Mogoantă

Parteneri:

Universitatea de Medicină și Farmacie „Carol Davila” din București – Responsabil partener: Dr. Ioan Lascăr

Institutului de Biologie şi Patologie Celulară ,,Nicolae Simionescu'', Bucureşti – Responsabil partener: Dr. Irina Titorencu

Universitatea Politehnica Bucureşti - Responsabil partener: Dr. Alexandru Grumezescu

Colaborator în granturi internaționale:

1. **PNRR–III-C9-2022-I8 CF 197/15.11.2022**

Planul Național de Recuperare și Reziliență al României (*Romania's National Recovery and Resilience Plan*) - Proiect finanţat de către Uniunea Europeană

Titlul proiectului: Îmbunătăţirea potențialului endogen anti-oxidant și de îndepărtare a colesterolului prin editare genică în boala ficatului gras; studii preclinice *(Enchancing the endogenous anti-oxidant and cholesterol removal potential by gene editing in fatty liver disease; pre-clinical studies)* - THERAGENLIV

Perioada: 2023-2026

Director de proiect: Prof. Shlomo Sasson

2. ***European Cooperation in Science and Technology***

***CA21108 - European Network for Skin Engineering and Modeling* (NETSKINMODELS)**

Perioada: 2022-2026

Director de proiect: Prof. Sandrine Dubrac

I.2.3.3. Tratamentul celulelor cu diverse molecule inflamatorii 54

I.2.4. Secretomul provenit de la MSC – o potenţială terapie pentru rănile cutanate 55

I.3. UTILIZAREA FIBROBLASTELOR CA ALTERNATIVĂ A MSC 59

I.3.1. Similitudinea dintre fibroblaste şi MSC 59

I.3.2. Utilizarea secretomului provenit de la fibroblaste în terapia rănilor cutanate.. 60

I.3.2.1. Studii *in vitro* 60

I.3.2.2. Studii *in vivo* 67

I.4. METODE PENTRU OBŢINEREA UNEI SURSE INEPUIZABILE DE CELULE MEZENCHIMALE 69

I.4.1. Imortalizarea celulelor mezenchimale 69

I.4.2. Obţinerea celulelor mezenchimale din celule stem pluripotente induse..... 77

II. CONTRIBUŢII ORIGINALE 80

II.1. OBŢINEREA ŞI CARACTERIZAREA MSC UMANE DERIVATE DIN MĂDUVA OSOASĂ ŞI DIN ŢESUTUL ADIPOS, PRECUM ŞI A FIBROBLASTELOR DERMALE UMANE PRIMARE SAU OBŢINUTE DIN CELULE STEM PLURIPOTENTE INDUSE UMANE 81

II.1.1. Introducere şi obiective 81

II.1.2. Materiale şi metode 81

II.1.2.1. Izolarea MSC umane din măduva osoasă 81

II.1.2.2. Izolarea MSC umane din ţesutul adipos 82

II.1.2.3. Izolarea fibroblastelor dermale primare 83

II.1.2.4. Obţinerea fibroblastelor dermale prin diferenţierea celulelor stem pluripotente induse umane 84

II.1.2.5. Microscopia electronică de transmisie (TEM) 85

II.1.2.6. Analiza imunofenotipică prin tehnica de citometrie în flux 86

II.1.2.7. Imagistică de fluorescenţă 87

II.1.2.8. Analiza potenţialului de diferenţiere către linia adipogenă, osteogenă şi condrogenă 88

II.1.3. Rezultate 88

II.1.3.1. Obţinerea culturilor pure de MSC primare umane derivate din măduva osoasă şi din ţesutul adipos, precum şi de fibroblaste dermale umane primare 88

II.1.3.2. În cultură, MSC primare umane derivate din măduva osoasă şi din ţesutul adipos, precum şi fibroblastele dermale umane primare exprimă markerii celulari de suprafaţă specifici şi au potenţial de diferenţiere către linia adipogenică, osteogenă şi condrogenică 92

II.1.3.3. Caracterizarea fibroblastelor dermale obţinute prin diferenţierea celulelor stem pluripotente induse umane 94

II.1.4. Discuţii şi concluzii parţiale..... 98

II.2. TESTAREA *IN VITRO* A SECRETOMULUI PROVENIT DE LA O LINIE IMORTALIZATĂ DE MSC DERIVATE DIN ŢESUT ADIPOS (ADSC) URMĂRIND EFECTUL ASUPRA PROCESELOR IMPLICATE ÎN VINDECAREA RĂNILOR CUTANATE..... 99

II.2.1. Introducere şi obiective..... 99

II.2.2. Materiale şi metode..... 100

II.2.2.1. Culturi celulare..... 100

II.2.2.2. Design experimental pentru obţinerea subpopulaţiei clonale de ADSC101

II.2.2.3. Cinetica proliferării celulare..... 102

II.2.2.4. Teste de diferențiere multilinie..... 102

II.2.2.5. Cariotiparea subpopulaţiei clonale de celule imortalizate..... 103

II.2.2.6. Analiza expresiei proteice prin Western Blot..... 104

II.2.2.7. Producerea, colectarea şi păstrarea secretomului..... 104

II.2.2.8. Testarea viabilităţii celulare..... 104

II.2.2.9. Testarea proliferării celulare..... 105

II.2.2.10. Evaluarea migrării celulare prin metoda zgârierii monostratului celular („Scratch test”)..... 105

CONCLUZII GENERALE 219

BIBLIOGRAFIE 220

INTRODUCERE ȘI OBIECTIVELE GENERALE

Vindecarea rănilor ţesutului cutanat este un proces fiziologic ce implică o succesiune de evenimente biologice și moleculare interconectate, ca răspuns la apariţia unei leziuni, rezultând reconstituirea integrităţii straturilor pielii şi restaurarea homeostaziei. În timpul acestui proces dinamic și complex, multiple căi biologice sunt activate și sincronizate, interacțiuni coordonate existând între celulele inflamatorii, fibroblastele (Fb) dermale, keratinocite și celulele endoteliale (Paul și Sharma, 2004; Reinke și Sorg, 2012). Totodată, celulele stem rezidente pot fi supuse auto-replicării şi diferențierii în mai multe tipuri celulare şi pot afecta implicit semnalizarea paracrină de la nivelul rănii, iar toate aceste atribute sunt cruciale pentru regenerarea tisulară (Chen și colab., 2009).

În funcție de durata procesului de vindecare, rănile cutanate sunt clasificate în acute și cronice (vindecabile și, respectiv, greu vindecabile) (Robson și colab., 2001). Rănile acute prezintă semne bine definite de recuperare în decurs de 4 până la 12 săptămâni, perioada de vindecare depinzând de amploarea leziunii. În unele cazuri, este imposibilă restabilirea în mod eficient a structurii și funcției normale a țesutului, procesul fiziologic de vindecare al rănilor fiind întrerupt, ca rezultat al disfuncționalităților în reglarea răspunsurilor de reparare tisulară, precum inflamația, angiogeneza, depunerea matricii extracelulare și recrutarea celulelor. Astfel, faza inflamatorie prelungită asociată cu o inflamație excesivă, scăderea angiogenezei, migrarea

și proliferarea slabă a keratinocitelor și Fb sunt elementele ce definesc rănile cronice (Falanga, 2005; Lazarus și colab., 1994).

În prezent, incidența rănilor cronice continuă să crească, reprezintând o provocare clinică semnificativă. De obicei, sunt afectați adulții cu comorbidități, precum ar fi insuficiența venoasă, diabetul, obezitatea, neuropatiile, insuficiența arterială sau cei care prezintă diverşi factori limitativi precum îmbătrânirea, infecțiile, alimentația deficitară, imunosupresia. Rănile cronice sunt clasificate în trei mari categorii: ulcere vasculare, ulcere diabetice și ulcere de presiune (Nunan și colab., 2014).

În ciuda eforturilor depuse de-a lungul timpului, rănile cutanate cronice și vindecarea acestora reprezintă provocări clinice majore, care implică o povară socială și medicală considerabilă. Există însă un interes semnificativ în utilizarea celulelor stem în gestionarea acestei probleme. În ultimele decenii medicina regenerativă a câştigat o atenție considerabilă, bazându-se pe refacerea, înlocuirea sau repararea celulelor, țesuturilor și organelor traumatizate, oferind astfel posibile metode de tratament.

Celulele stromale mezenchimale (MSC) joacă un rol important în acest domeniu. Acestea sunt definite drept un grup heterogen de celule progenitoare nespecializate fusiforme (formă asemănătoare cu cea a Fb), de origine mezodermică, aderente la plastic în condiţii de cultură standard şi capabile să se auto-reînnoiască prin diviziune și să se diferențieze în mai multe linii celulare (Wei și colab., 2013). Aceste celule au fost identificate pentru prima dată în măduva osoasă (BM), însă, recoltarea celulelor de la nivelul BM (aspirat provenit din BM) este o procedură invazivă şi dureroasă, cu randament scăzut de obţinere a MSC (Pittenger și colab., 1999).

Aceste limitări au condus la căutarea unor modalităţi alternative de obținere a celulelor stromale mezenchimale, precum ar fi recoltarea acestora de la nivelul ţesutului adipos sau din alte surse tisulare, ca de exemplu gelatina Wharton, sângele din cordonul ombilical, placenta, lichidul amniotic etc. (Keating, 2006; Ullah și colab., 2015; Gottipamula și colab., 2018; Eom și colab., 2011). Cu toate acestea, sunt preferate sursele care permit proceduri de recoltare minim invazive precum și izolarea unor cantități abundente de celule, cum ar fi ţesutul adipos (Kuhbier și colab., 2010).

Iniţial s-a studiat capacitatea de diferenţiere a MSC ca potenţială terapie regenerativă în vindecarea rănilor ţesutului cutanat. S-a demonstrat însă că transplantul de MSC la locul leziunii acționează în primul rând prin efecte paracrine indirecte, mai degrabă decât prin înlocuirea directă a celulelor afectate. Această acţiune paracrină este datorată secretomului constituit din factorii solubili (citokine, chemokine) şi veziculele extracelulare secretate de celule în spaţiul extracelular. Astfel, în prezent se încearcă abordarea unor noi metode terapeutice acelulare care vizează utilizarea secretomului MSC în vindecarea rănilor prin stimularea angiogenezei, modularea inflamației, reducerea formării cicatricilor și inducerea re-epitelizării (Zarei și Soleimaninejad, 2018; Guillamat-Prats, 2021; Ahangar și colab., 2020). În comparație cu utilizarea celulelor, această terapie acelulară este mai puțin imunogenă și prezintă un risc minim de formare a tumorilor (Vizoso și colab., 2017; Lu și colab., 2017; Ha și colab., 2020), oferind de asemenea şi avantaje în ceea ce privește manipularea și siguranța.

Celulele prezintă un număr limitat de multiplicări (dublări de populaţie) *in vitro,* instalându-se destul de repede senescenţa şi implicit moartea acestora. Astfel, pentru a depăși această limitare, se utilizează tehnici de reactivare a telomerazei (enzima ce contribuie la menţinerea lungimii telomerelor), celulele realizând un număr nelimitat de diviziuni sau metode de inactivare a proteinelor implicate în reglarea ciclului celular. Totodată, celulele obținute prin această metodă sunt similare sau identice din punct de vedere genetic și fenotipic cu celulele de origine. Această abordare poartă numele de ,,imortalizare celulară'' și a fost posibilă datorită cunoașterii bazelor moleculare care susțin acest fenomen *in vivo* în cazul cancerului (Ivanković și colab., 2007; Chalak și colab., 2024; de Bardet și colab., 2023).

Fb și MSC prezintă numeroase caracteristici comune: morfologia fusiformă, localizarea la nivelul țesutului conjunctiv, potenţialul proliferativ, expresia markerilor de suprafaţă specifici, multipotența, lipsa activităţii telomerazei, cât şi tiparele de expresie genică. Mai mult decât atât, acestea prezintă funcţii similare în reglarea imunității. Datorită acestor asemănări, Fb ar putea fi utilizate ca potențială alternativă a MSC pentru utilizarea în aplicații clinice care implică regenerarea țesuturilor, spre exemplu pentru tratamentul rănilor cutanate. Acestea pot fi recoltate cu ușurință în număr mare din diverse țesuturi biologice, cum ar fi pielea, țesutul adipos și gingival, în timp ce sursa cea mai frecvent utilizată de MSC, BM, oferă relativ puțin material de pornire pentru expansiunea celulară și necesită metode de recoltare invazive. În plus, timpul de dublare al populației este semnificativ mai scurt comparativ cu MSC, senescenţa Fb instalându-

se după mai mult de 50 dublări populaţionale (Huang și colab., 2010). Totodată, cerințele mediilor de cultură pentru expandarea și menținerea Fb în cultură nu sunt unele complexe.

Pe de altă parte, potențialul regenerativ al celulelor mezenchimale este influențat de diverși factori, cum ar fi țesutul de origine, vârsta donatorului, condițiile de cultură sau prezența factorilor inflamatori din organism (Ferreira și colab., 2018). Din acest motiv, mai multe strategii de precondiționare a MSC *in vitro*, precum ar fi cultivarea în condiţii hipoxice, în sistem 3D sau tratamentul cu factori inflamatori, au fost utilizate pentru a stimula proprietățile lor secretorii (Haider and Ashraf, 2010; Lu și colab., 2010). Mai mult decât atât, fibroblastelor cultivate sub formă de agregate le-a fost atribuit de către Vaheri și colab. conceptul de ,,nemoză'' (Vaheri și colab., 2009). Mai exact, această noţiune este definită ca o modalitate de activare a celulelor, care este caracterizată prin creșterea producției de COX-2 (ciclooxigenază-2), secreția de prostaglandine, proteinaze, citokine chemotactice, HGF (factorul de creștere al hepatocitelor), VEGF (factorul de creștere endotelial vascular) și exprimarea factorului nuclear activat-kappa B (Vaheri și colab., 2009; Enzerink și colab., 2010). Astfel, prin acest proces pot fi îmbunătăţite proprietăţile paracrine ale Fb, ce pot sta la baza strategiilor terapeutice care utilizează secretomul (terapii ,,fără celule'').

De asemenea, generarea de MSC din celule stem pare să ofere oportunitatea unică de a depăşi majoritatea obstacolelor care există în prezent în ceea ce priveşte utilizarea pe scară largă a MSC ca terapie inovatoare. De-a lungul timpului, s-a raportat faptul că celulele stem pluripotente induse (iPSC) pot fi diferenţiate în MSC, precum şi în Fb. Acestea provin dintr-o singură clonă de iPSC, prezentând omogenitate ridicată pentru aplicații clinice. Mai mult decât atât, performanța lor biologică este mai stabilă și mai previzibilă, întrucât tiparul molecular al MSC native se schimbă subtil între diferite loturi.

Astfel, **scopul** acestei tezei de doctorat a fost de a evalua efectele secretomului provenit de la celulele mezenchimale umane asupra procesului de vindecare a rănilor, atât *in vitro*, cât şi *in vivo* pe un model murin de rană. Pentru îndeplinirea acestui scop au fost propuse mai multe **obiective** utilizându-se surse celulare multiple, toate de origine umană.

Obiectiv 1. Obţinerea şi caracterizarea celulelor stromale mezenchimale (MSC) umane derivate din măduva osoasă și din țesutul adipos, precum și a fibroblastelor dermale umane primare sau obţinute din celule stem pluripotente induse umane.

Obiectiv 2. Testarea *in vitro* a secretomului provenit de la o linie imortalizată de MSC derivate din ţesut adipos (ADSC) urmărind efectul asupra proceselor implicate în vindecarea rănilor cutanate.

Obiectiv 3. Studiu comparativ privind proprietăţile fibroblastelor dermale umane şi a MSC umane derivate din măduva osoasă cultivate în sistem bi- (2D) şi tridimensional (3D).

Obiectiv 4. Testarea *in vitro* a efectului secretomului provenit de la fibroblastele dermale primare şi de la fibroblastele derivate din celulele stem pluripotente induse umane cultivate în sistem 2D şi 3D asupra proceselor implicate în vindecarea rănilor cutanate.

Obiectiv 5. Testarea *in vivo* a secretomului provenit de la fibroblastele dermale primare umane cultivate în sistem 2D şi 3D privind acţiunea acestuia asupra proceselor implicate în vindecarea rănilor cutanate.

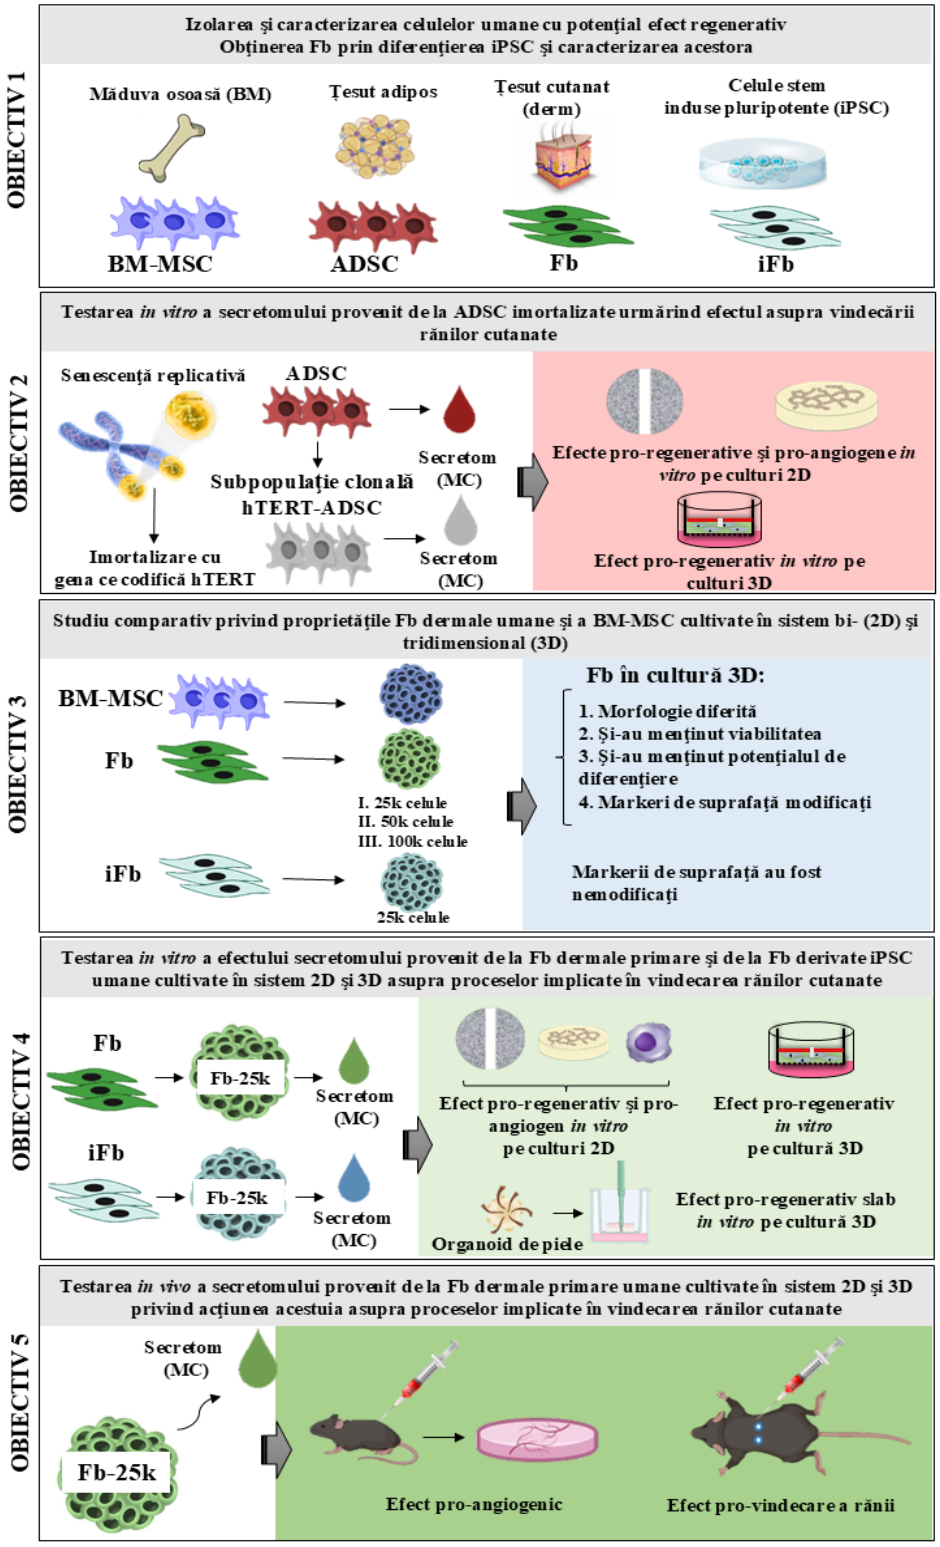
STRUCTURA TEZEI DE DOCTORAT

Teza este structurată în **9 capitole**, cuprinzând atât noţiuni teoretice privind stadiul actual al cunoştinţelor, cât şi rezultatele originale obţinute (partea de contribuţii originale).

Prima parte („Stadiul actual al cunoașterii") este structurată în ***4 capitole*** şi cuprinde date din literatură aduse la zi cu privire la subiectul vizat de această teză. Mai exact, în **capitolul I.1** este prezentată problematica rănilor cutanate, fiind vizate fundamentele anatomice şi fiziologice ale ţesutului cutanat, etapele vindecării rănilor alături de prezentarea succintă a perturbării procesului fiziologic întâlnit în cazul rănilor cronice, dar și abordările terapeutice actuale. **Capitolul I.2** vizează caracteristicile definitorii ale contribuţiei secretomului provenit de la MSC în procesul de vindecare al rănilor cutanate, punându-se accent pe caracterizarea MSC, descrierea compoziţiei secretomului provenit de la acestea, dar şi prezentarea metodelor actuale de potenţare a efectelor. De asemenea, sunt expuse studiile din literatură ce presupun utilizarea secretomului provenit de la celulele stromale mezenchimale drept potenţială terapie pentru rănile cutanate. **Capitolul I.3** se concentrează pe conceptul de utilizare a Fb ca alternativă a MSC, fiind prezentate similitudinile dintre acestea, dar şi studiile existente privind

aplicabilitatea secretomului provenit de la Fb drept posibilă terapie pentru rănile cutanate. În **Capitolul I.4** sunt prezentate potenţiale direcţii pentru obţinerea unei surse inepuizabile de celule mezenchimale: imortalizarea celulară, precum şi generarea acestora din iPSC. Unele date cuprinse în această parte fac parte dintr-un articol de tip *review* publicat anul acesta într-un jurnal indexat ISI: **Gheţu, D-.M.**, Raymond, K., Titorencu, I., Simionescu, M. **2025.** Innovative Strategies: Use of Stromal Cell-Derived Secretome for Chronic Wound Therapy. *International Journal of Molecular Sciences*, *26*(12), p.5609. 10.3390/ijms26125609 (IF/2024 = 4.9, Q1, AIS = 1.121).

A doua parte („Contribuţii originale”) este structurată în ***5 capitole*** care au avut la bază cele 5 obiective enunţate anterior. Astfel, pentru îndeplinirea obiectivelor propuse au fost utilizate tehnici precum cele de culturi celulare, citometrie în flux, biologie moleculară, histologie, precum şi teste pe animale, toate acestea fiind descrise în secţiunile „Materiale şi Metode” aferente fiecărui studiu. Conţinutul capitolelor este schematizat în figura de mai jos şi prezentat succint în cele ce urmează.



Schematizarea conținutului celor 5 capitole (obiective) cuprinse în partea a doua a tezei („Contribuții originale”). MC: mediu condiționat; hTERT: subunitatea catalitică a telomerazei umane.

Capitolul II.1 al tezei este asociat cu primul obiectiv (Obiectiv 1), fiind intitulat „**Obţinerea şi caracterizarea celulelor stromale mezenchimale (MSC) umane derivate din măduva osoasă și din țesutul adipos, precum și a fibroblastelor dermale umane primare sau obţinute din celule stem pluripotente induse umane**”. Acesta prezintă obţinerea de celule primare cu potențial regenerativ pentru vindecarea rănilor (MSC derivate din BM şi ţesut adipos şi Fb izolate de la nivelul dermului) şi caracterizarea acestora din punct de vedere al markerilor specifici şi al capacităţii de diferenţiere către liniile celulare mezodermice: linia adipogenă, osteogenă şi condrogenă. Mai mult decât atât, acesta este axat şi pe obţinerea Fb prin diferenţierea din iPSC şi caracterizarea acestora din punct de vedere al markerilor de suprafaţă şi intracelulari specifici (precum vimentina şi colagenul). Descrierea amănunțită a protocoalelor poate fi regăsită în secțiunea „Materiale și metode” aferentă acestui capitol. Rezultatele arată succesul izolării de celule primare care exprimă markerii specifici şi deţin capacitatea de diferenţiere către liniile celulare mezodermice. De asemenea, au fost obţinute Fb prin diferenţierea iPSC (iFb), exprimând markerii de suprafaţă şi intracelulari specifici. Aceste celule au fost folosite în experimentele *in vitro* şi *in vivo* pentru îndeplinirea celorlalte obiective propuse, care au ca scop utilizarea secretomului (mediului condiţionat) drept terapie „acelulară” pentru rănile cutanate.

Capitolul II.2 (Obiectiv 2) este intitulat „**Testarea *in vitro* a secretomului provenit de la o linie imortalizată de MSC derivate din ţesut adipos (ADSC) urmărind efectul asupra proceselor implicate în vindecarea rănilor cutanate**”. În cadrul acestuia este prezentată generarea unei linii imortalizate de ADSC (subpopulaţie clonală) prin transducția lentivirală a genei care codifică transcriptaza inversă (componenta catalitică) a telomerazei umane (hTERT) pentru inhibarea fenomenului de senescenţă replicativă şi evaluarea *in vitro* a efectelor secretomului (mediului condiţionat) provenit de la aceste celule asupra proceselor cheie asociate vindecării rănilor cutanate. Pe scurt, s-a raportat impactul secretomului (mediului condiţionat) asupra proliferării și migrării keratinocitelor, Fb şi celulelor endoteliale, cât și asupra angiogenezei (procese care au loc în timpul fazei proliferative a vindecării rănilor). Totodată a fost demonstrat şi efectul de susținere a procesului de re-epitelizare a unei răni realizate pe un model de cultură organotipică de piele umană. Rezultatele expuse în acest capitol au fost cuprinse într-o lucrare publicată într-un jurnal indexat ISI: **Iacomi, D. M.**, Roşca A. M., Ţuţuianu, R., Neagu, T. P., Prună, V., Simionescu, M., Titorencu, I. **2022**. Generation of an

immortalized human adipose-derived mesenchymal stromal cell line suitable for wound healing therapy. *International Journal of Molecular Sciences*, 23(16):8925. DOI: 10.3390/ijms23168925 (IF/2022 = 5.6, Q1, AIS = 1.028).

Capitolul II.3 (Obiectiv 3) intitulat „**Studiu comparativ privind proprietăţile fibroblastelor dermale umane şi a MSC umane derivate din măduva osoasă cultivate în sistem bi- (2D) şi tridimensional (3D)**" a implicat analiza comparativă a BM-MSC şi a Fb dermale primare umane (ca sursă celulară alternativă mult mai accesibilă)/diferenţiate din iPSC cultivate în sistem 3D (drept strategie de îmbunătăţire a capacităţii secretorii), mai exact în agregate celulare (sferoizi) obţinute prin cultivarea suspensiei celulare în picături suspendate („*hanging drops*"). Sferoizii/celulele primare din componenţa acestora au fost analizaţi/analizate din punct de vedere al morfologiei, viabilităţii, secreţiei componentelor matricei extracelulare, prezenţei moleculelor de adeziune, dar şi de menţinere al markerilor de suprafaţă specifici şi a potenţialului de diferenţiere către linia adipogenă, osteogenă şi condrogenă. Rezultatele au arătat că ambele tipuri celulare primare prezintă capacitatea de a agrega în sferoizi după 72 de ore, fiind detectată secreţia elementelor matricii extracelulare, menţinerea potenţialului de diferenţiere, însă şi unele modificări morfologice şi de prezenţă a markerilor de suprafaţă specifici. Din punct de vedere al viabilităţii nu s-au remarcat modificări semnificative în urma procesului de agregare. Fb diferenţiate din iPSC au format de asemenea sferoizi, menţinându-şi markerii de suprafaţă specifici în urma agregării. Datele originale cuprinse în acest studiu fac parte dintr-un articol în curs de redactare.

În **capitolul II.4** (Obiectiv 4) - „**Testarea *in vitro* a efectului secretomului provenit de la fibroblastele dermale primare şi de la fibroblastele derivate din celulele stem pluripotente induse umane cultivate în sistem 2D şi 3D asupra proceselor implicate în vindecarea rănilor cutanate**" – sunt prezentate rezultatele obţinute *in vitro* privind evaluarea efectelor secretomului (mediului condiţionat) provenit de la Fb dermale primare cultivate în sistem 3D (sferoizi) asupra proceselor cheie asociate vindecării rănilor cutanate: inflamaţia, angiogeneza şi re-epitelizarea, comparativ cu efectele mediului condiţionat provenit de la Fb cultivate în monostrat (2D). S-a arătat creşterea secreţiei factorilor pro-angiogenici prin cultivarea tridimensională (3D) a Fb dermale umane primare sub formă de sferoizi (25000 celule/sferoid – 25k), îmbunătăţirea proceselor de migrare şi proliferare, cât şi de re-epitelizare la nivelul rănii pe un model 3D de cultură organotipică de piele în prezenţa mediului condiţionat

provenit de la aceste celule. Astfel, rezultatele obţinute confirmă faptul că secretomul provenit de la aceste celule cultivate în sistem 3D reprezintă astfel o posibilă strategie de tratament pentru vindecarea rănilor. Totodată, sunt prezentate şi rezultatele privind evaluarea secretomului obţinut de la Fb derivate din iPSC (iFb) cultivate atât în sistem 2D cât şi 3D (25000 celule/sferoid), însă nefiind evidenţiat un efect de potenţare a re-epitelizării pe un model 3D al unui echivalent de piele obţinut din organoizi. Datele originale cuprinse în acest studiu fac parte dintr-un articol în curs de redactare.

Ultimul capitol al părţii originale, **capitolul II.5** (Obiectiv 5) **-** „**Testarea *in vivo* a secretomului provenit de la fibroblastele dermale primare umane cultivate în sistem 2D şi 3D privind acţiunea acestuia asupra proceselor implicate în vindecarea rănilor cutanate**" este asociat cu evaluarea *in vivo* a efectelor secretomului (mediului condiţionat) provenit de la Fb dermale primare cultivate în sistem 3D (sferoizi alcătuiţi din 25000 celule/25k) din punct de vedere al angiogenezei şi al procesului de re-epitelizare, comparativ cu efectele mediului condiţionat provenit de la Fb cultivate în monostrat. Pe scurt, rezultatele au arătat efectul benefic al secretomului provenit de la Fb dermale umane primare asupra angiogenezei şi a re-epitelizării rănilor cutanate, utilizându-se tehnica Matrigel *plug assay* şi un model de rană la şoareci. Datele originale cuprinse în acest studiu fac de asemenea parte dintr-un articol în curs de redactare.

Conţinutul tezei se încheie cu referințele bibliografice aferente.

CONTRIBUŢII PERSONALE

LISTA LUCRĂRILOR PUBLICATE ŞI COMUNICATE PE DURATA PROGRAMULUI DOCTORAL

Lucrări publicate în reviste indexate ISI – autor principal

1. **Gheţu, D.-M**, Raymond, K., Titorencu, I., Simionescu, M. **2025**. Innovative Strategies: Use of Stromal Cell-Derived Secretome for Chronic Wound Therapy. *International Journal of Molecular Sciences*, 26(12). DOI: (IF/2024 = 4.9, Q1, AIS = 1.121).

2. Sorca†, B. V., Kaya, D. A., Kaya, M. G. A., Enăchescu, M., **Ghetu†, D.-M.**, Enache, L.-B., Boeraşu, I., Coman, A. E., Rusu, L. C., Constantinescu, R., Titorencu, I. **2025**. Bone Fillers

with Balance Between Biocompatibility and Antimicrobial Properties. *Biomimetics*, 10(2), 100. DOI: 10.3390/biomimetics10020100 (IF/2023 = 3.4, Q2, AIS = 0.567).

A/00370 (25.06.2021): „Hidrogeluri polimerice compozite cu proprietăţi antibacteriene şi cicatrizante şi procedeu de obţinere a acestora"; Autori: Simionescu M., Roşca A.M., Titorencu I.D., **Iacomi M.D.**, Ţuţuianu R., Prună V., Lasca I., Chercheriţă I.A., Neagu P.T., Mogoantă L., Mogoşanu G.D., Pirici N.D., Streba C.T., Birca A.C., Burduşel A.C., Stoica A.E., Grumezescu A.L., Chircov C.

CURSURI ŞI SEMINARII EFECTUATE PE DURATA PROGRAMULUI DOCTORAL

1. Training School (Școala de formare) "3D Skin Cultures" organizată în cadrul acțiunii COST CA21108 – Rețeaua Europeană pentru Ingineria și Modelarea Pielii (NETSKINMODELS) – 29 iunie-2 iulie 2025, Nijmegen, Țările de Jos.

2. Prof. Dimitris Kardassis: Lectures to the students (Lipoprotein pathways and their roles in the pathophysiology of atherosclerosis; Transcriptional Regulation of Cardiovascular Genes: Basic principles and methodologies *in vitro* and *in vivo*; Hormone Nuclear receptors: from basic

biology to clinical exploitation in cardiovascular disease), 14-18 noiembrie 2024, Institutul de Biologie şi Patologie Celulară ,,Nicolae Simionescu'', Bucureşti, România.

3. Curs de formare realizat la Universitatea de Medicină şi Farmacie ,,Carol Davila'' din Bucureşti intitulat ,,*Ştiinţa animalelor de laborator"* în perioada 30.01-10.02.2023.

4. INTERA-1 Summer School ,,*Encapsulation of cells and drugs: materials, procedures and applications"*, 13-14 mai 2021, Institutul de Biologie şi Patologie Celulară ,,Nicolae Simionescu'', Bucureşti, România.

5. INTERA Online Workshop ,,*Recent advances in the field of obtaining nanovectors for gene transfection*'', 22 aprilie 2021, Institutul de Biologie şi Patologie Celulară ,,Nicolae Simionescu'', Bucureşti, România.

6. THERAVALDIS Online Workshop ,,*Diabetes in cardiovascular diseases; pathogenic mechanisms and targeted therapies*'', 27 noiembrie 2020, Institutul de Biologie şi Patologie Celulară ,,Nicolae Simionescu'', Bucureşti, România.

7. DIABETER Online Workshop *,,A new therapeutic tool in autoimmune diabetes: Mesenchymal Stromal Cell"*, 20 noiembrie 2020, Institutul de Biologie şi Patologie Celulară ,,Nicolae Simionescu'', Bucureşti, România.

STAGII INTERNAŢIONALE

1. Stagiu internaţional cu o durată de 9 luni (1.09.2023-31.05.2024) realizat la Centrul Medical al Universităţii din Leiden, Ţările de Jos, beneficiind de o bursă acordată de Ministerul Educației din România (conform HG 118/2023).

PREMII

1. Premiul oferit de Ministerul Educației și Cercetării și UEFISCDI ,,Realizări științifice – Articol original '', PN IV, Program 5.2 - Resurse umane – Subprogram 5.2.3 – Suport – Lista 1 – Primele aplicaţii trimise pentru articolele din 2021 şi 2022_13.03.2023 pentru articolul ,,Generation of an immortalized human adipose-derived mesenchymal stromal cell line suitable for wound healing therapy'' publicat în revista ,,International Journal of Molecular Sciences'', Volumul 23 (16), 8925, având factorul de impact în 2022 = 5.6 (**Iacomi, D. M.**, Roşca, A. M., Ţuţuianu, R., Neagu, T. P., Prună, V., Simionescu, M., Titorencu, I.).

2. Premiul oferit de Ministerul Educației și Cercetării și UEFISCDI „Realizări științifice – Articol original ”, Subprogramul 1.1 - Resurse umane - Acordarea rezultatelor cercetării - Articole, Concurență 2021, Rezultatele evaluării_Lista 2 - Cereri de premiere depuse pentru articolele publicate în 2021_18.11.2021 - pentru articolul „Human mesenchymal stromal cell-derived exosomes promote in vitro wound healing by modulating the biological properties of skin keratinocytes and fibroblasts and stimulating angiogenesis” publicat în revista „International Journal of Molecular Sciences”, Volumul 22(12), 6239, 2021, având factorul de impact în 2021 = 5.924 (Ţuţuianu, R., Roşca, A. M., **Iacomi, D. M.**, Simionescu, M., Titorencu, I.).

BURSE OBȚINUTE PE DURATA PROGRAMULUI DOCTORAL ȘI FINANŢAREA CERCETĂRILOR

BURSE

1. Bursă acordată de către Ministerul Educaţiei pentru realizarea unui stagiu de cercetare în străinătate (conform HG 118/2023) la Centrul Medical al Universităţii din Leiden, Ţările de Jos cu durată de 9 luni (1.09.2023-31.05.2024).
2. Bursă de doctorat - Şcoala de Studii Avansate a Academiei Române (2020-2023).

COLABORĂRI ÎN PROIECTE DE CERCETARE

Colaborator în granturi naționale:

1. **PN-IV-P7-7.1-PED-2024-1446**

Proiect experimental demonstrativ

Titlul proiectului**:** Substituenţi inovativi cu structură tridimensională şi activitate antimicrobiană pe bază de colagen pentru reconstrucţia cranio-facială (*Innovative antimicrobial collagen based three dimensional scaffolds for craniofacial reconstruction*)

Perioada: 2025-2027

Coordonator: Institutul de Biologie şi Patologie Celulară „Nicolae Simionescu”, Bucureşti

Director de proiect: Dr. Irina Titorencu

Partener: LMS PLASTIC SURGERY CLINIQUE SRL – Dr. Ana Căruntu

2. **PN-III-P1-1.1-TE-2021-1344**

Proiect de cercetare pentru stimularea constituirii de tinere echipe de cercetare independente

Titlul proiectului: Îmbunătățirea proprietăților paracrine ale fibroblastelor prin agregare tridimensională pentru terapia rănilor cronice *(Enhancing the paracrine properties of fibroblasts by three-dimensional aggregation for chronic wounds therapy)* - FIBROTHER

Perioada: 2022-2024

Director de proiect: Dr. Roşca Ana-Maria

3. **PN-III-P2-2.1-PED-2021-4275**

Proiect experimental demonstrativ

Titlul proiectului: Optimizarea interacţiunii celulelor stem mezenchimale umane cu structuri biomimetice inovative cu aplicabilitate în ingineria tisulară *(Optimization of human mesenchymal stem cells interaction with innovative biomimetic structures for tissue engineering applications)* - BioMimCells

Perioada: 2022-2024

Coordonator: Universitatea Politehnica Bucureşti

Director de proiect: Dr. ing. Diana Maria Vrânceanu

Parteneri:

Institutul de Biologie şi Patologie Celulară „Nicolae Simionescu”, Bucureşti - Responsabil partener: Dr. Irina Titorencu

Institutul National de Cercetare şi Dezvoltare în Optoelectronică (INOE 2000) - Responsabil partener: Dr. Alina Vlădescu

4. **PN III PCCDI 45/2018**

Proiecte complexe realizate în consorţii Cercetare Dezvoltare Inovare

Titlul proiectului: Nanostructuri bioactive pentru strategii terapeutice inovatoare (*Bioactive Nanostructures for Innovative Therapeutic Strategies*) - NANOLIFE

Perioada: 2018-2020

Coordonator: Universitatea de Medinică şi Farmacie din Craiova

Director de proiect: Dr. Laurenţiu Mogoantă

Parteneri:

Universitatea de Medicină și Farmacie „Carol Davila” din București – Responsabil partener: Dr. Ioan Lascăr

Institutului de Biologie şi Patologie Celulară ,,Nicolae Simionescu'', Bucureşti – Responsabil partener: Dr. Irina Titorencu

Universitatea Politehnica Bucureşti - Responsabil partener: Dr. Alexandru Grumezescu

Colaborator în granturi internaționale:

1. **PNRR–III-C9-2022-I8 CF 197/15.11.2022**

Planul Național de Recuperare și Reziliență al României (*Romania's National Recovery and Resilience Plan*) - Proiect finanţat de către Uniunea Europeană

Titlul proiectului: Îmbunătăţirea potențialului endogen anti-oxidant și de îndepărtare a colesterolului prin editare genică în boala ficatului gras; studii preclinice *(Enchancing the endogenous anti-oxidant and cholesterol removal potential by gene editing in fatty liver disease; pre-clinical studies)* - THERAGENLIV

Perioada: 2023-2026

Director de proiect: Prof. Shlomo Sasson

2. ***European Cooperation in Science and Technology***

***CA21108 - European Network for Skin Engineering and Modeling* (NETSKINMODELS)**

Perioada: 2022-2026

Director de proiect: Prof. Sandrine Dubrac

ŞCOALA DE STUDII AVANSATE A ACADEMIEI ROMÂNE

INSTITUTUL DE BIOLOGIE ŞI PATOLOGIE CELULARĂ
„NICOLAE SIMIONESCU" AL ACADEMIEI ROMÂNE

TEZĂ DE DOCTORAT

Identificarea şi analiza microARN asociaţi lipoproteinelor serice; corelaţii cu parametrii clinici şi biochimici ai pacienţilor cu boli cardiovasculare

REZUMAT

Conducător ştiinţific:
Acad. ANCA V. SIMA

Doctorand:
NATALIA SIMIONESCU

BUCUREŞTI
2017

CUPRINS

CUVÂNT ÎNAINTE **1**
INTRODUCERE ŞI OBIECTIVE **3**
LISTĂ ABREVIERI **6**

PARTEA I – STADIUL ACTUAL AL CUNOŞTINŢELOR
I.1. ATEROSCLEROZA ARTERELOR CORONARE **8**
Structura inimii 8
Fiziologia inimii 10
Circulaţia coronariană 11
Formarea plăcii aterosclerotice 12
Ateroscleroza arterelor coronare 15
Boala coronariană stabilă 17
Sindromul coronarian acut 18

I.2. LIPOPROTEINE SERICE **19**
Proprietăţile şi compoziţia principalelor lipoproteine serice umane 19
Metabolismul lipoproteinelor serice 23
Lipoproteine pro-aterogene 28
Lipoproteine anti-aterogene – HDL 29

I.3. MICRO-ARN PREZENŢI ÎN CIRCULAŢIA SANGVINĂ **32**
Nomenclatura miRNA 33
Organizarea genomică a microARN 34
Biosinteza microARN 34
MicroARN implicaţi în metabolismul LDL 38
MicroARN implicaţi în metabolismul HDL 39
MicroARN ce influenţează evoluţia plăcii aterosclerotice 40
MicroARN circulanţi 42
MicroARN în circulaţia sangvină a pacienţilor cu boli cardiovasculare şi patologii asociate 44
Problematica investigării miRNA prezenţi în circulaţia sangvină 46

PARTEA II – CONTRIBUŢII ORIGINALE

OBIECTIVELE GENERALE ALE PROIECTULUI 48

II.1. IDENTIFICAREA ŞI ANALIZA MICRO-ARN ÎN SERURI ŞI LIPOPROTEINE IZOLATE DE LA PACIENŢI HIPERLIPIDEMICI ŞI/SAU HIPERGLICEMICI 49

Introducere şi obiective 49

Protocoale experimentale şi metode de analiză 50

Selecţia pacienţilor şi încadrarea în grupe 50

Metode de analiză a parametrilor lipidici şi inflamatori în serul pacienţilor 51

Izolarea lipoproteinelor prin ultracentrifugare în gradient de densitate 54

Izolarea microARN din ser şi lipoproteine 55

Realizarea profilului microARN serici (screening) 56

Revers-transcrierea microARN şi real time-PCR cantitativ 57

Analiza statistică a datelor 58

Rezultate 59

Parametrii serici lipidici şi inflamatori 59

Profilul microARN în seruri hiperlipidemice şi/sau hiperglicemice 59

Analiza microARN selectaţi în serurile individuale 67

Corelarea nivelurilor de microARN serici cu parametrii lipidici şi inflamatori 70

Asocierea microARN cu lipoproteinele serice 73

Discuţii şi concluzii 74

II.2. IDENTIFICAREA ŞI ANALIZA MOLECULELOR DE MICRO-ARN SERICE SAU ASOCIATE CU LIPOPROTEINE IZOLATE DE LA PACIENŢI CU BOLI CORONARIENE 78

Introducere şi obiective 78

Protocoale experimentale şi metode de analiză 79

Selecţia pacienţilor cu boală coronariană (CAD); criterii clinice 79

Metode de analiză a parametrilor serici lipidici şi inflamatori 82

Protocoale de izolare şi caracterizare a lipoproteinelor serice 83

Izolarea microARN din seruri şi lipoproteine 84

Analiza profilului seric al unor microARN asociaţi cu CAD 84

Revers-transcrierea microARN şi real time-PCR cantitativ 85
Analiza statistică a datelor 86
Rezultate **87**
Parametrii serici şi caracteristicile clinice ale pacienţilor 87
Profilul microARN în serurile pacienţilor CAD 90
Analiza microARN selectaţi în serurile pacienţilor CAD 95
Distribuţia microARN în lipoproteine de la pacienţi CAD 97
Distribuţia microARN în lipoproteine izolate de la pacienţi CAD după 12 luni de la includerea în studiu 100
Discuţii şi concluzii **102**

II.3. EFECTUL HIPERGLICEMIEI ASUPRA MICRO-ARN CIRCULANŢI ŞI STIMULAREA PRODUCŢIEI DE MICRO-ARN ÎN MACROFAGE UMANE ÎN CULTURĂ DE CĂTRE SERURILE HIPERGLICEMICE DE LA PACIENŢI CU BOLI CORONARIENE **105**
Introducere şi obiective **105**
Protocoale experimentale şi metode de analiză **106**
Selecţia pacienţilor; criterii clinice 106
Metode de analiză a parametrilor serici 107
Izolarea şi caracterizarea lipoproteinelor serice 108
Analiza miRNA în seruri şi lipoproteine 108
Culturi celulare şi model experimental 108
Analiza miRNA şi a expresiei genice în macrofagele THP-1 109
Analiza statistică 111
Rezultate **111**
Caracteristicile clinice şi parametrii serici ale pacienţilor 111
Analiza microARN în serurile pacienţilor CAD normoglicemici şi hiperglicemici 113
Analiza microARN în HDL izolate din serurile pacienţilor CAD normoglicemici şi hiperglicemici 117
Serurile ACS induc creşterea expresiei genice a proteinelor maşinăriei de procesare şi producţia miRNA în macrofagele umane 120
Concentraţiile crescute de glucoză cresc producţia miRNA în macrofage umane expuse la serurile pacienţilor CAD 122
Discuţii şi concluzii **124**

III. CONCLUZII GENERALE **127**
PERSPECTIVE **127**

IV. BIBLIOGRAFIE **128**

Lucrări publicate în cadrul tezei de doctorat **154**
Rezumate ale lucrărilor prezentate la manifestări ştiinţifice **155**
Specializări şi cursuri efectuate **158**
Premii naţionale obţinute **159**
Burse câştigate prin competiţie pentru participarea la manifestări ştiinţifice internaţionale **159**
Finanţarea cercetărilor **160**

Cuvinte cheie: ateroscleroză, microARN, hiperlipidemie, hiperglicemie, boală coronariană, angină stabilă, sindrom coronarian acut, lipoproteine, model regresie logistică, biostatistică, monocite/macrofage.

Bolile cardiovasculare (CVD) sunt cauza principală de morbiditate şi mortalitate în lume, în ciuda cercetărilor ample şi a terapiilor aflate în continuă îmbunătăţire. Ateroscleroza şi complicaţiile sale sunt responsabile de iniţierea şi evoluţia a mare parte din bolile cardiovasculare. Ateroscleroza este o boală cronică inflamatorie, generată sau agravată de dereglări ale metabolismului lipidelor şi al glucozei [1-3].

Boala arterelor coronare (*coronary artery disease*, CAD) este rezultatul dezvoltării plăcilor aterosclerotice în peretele arterelor coronare. În primele stadii de formare a plăcii, celulele endoteliale se activează şi virează către un fenotip secretor, ducând la dezvoltarea unei lamine bazale hiperplazice şi la expresia de molecule chemoatractante ce duc la recrutarea celulelor inflamatoare din sânge [4]. Monocitele circulante aderă la endoteliu, pătrund în subendoteliu şi se diferenţiază în macrofage, devenind actorii principali în evoluţia plăcii aterosclerotice [5]. Proteinele serice, lipoproteinele aterogene (LDL) şi lipoproteinele anti-aterogene (HDL) ajung în subendoteliu prin transcitoză *via* celulele endoteliale [6]. Lipoproteinele se acumulează în lamina bazală hiperplazică şi în matricea extracelulară, suferă modificări şi interacţionează cu macrofagele, ducând la încărcarea acestora cu lipide şi formarea celulelor spumoase [4].

Progresul şi stabilitatea plăcii aterosclerotice sunt dificil de evaluat şi de aceea este importantă găsirea unor metode neinvazive pentru a urmări evoluţia CAD şi, în special, a sindromului coronarian acut (ACS). De asemenea, un aspect important este diagnosticul timpuriu şi identificarea unor noi ţinte moleculare ce pot ajuta la o intervenţie terapeutică rapidă, care poate îmbunătăţi prognosticul.

Din întregul genom, secvenţele care codează sinteza proteinelor reprezintă mai puţin de 3%, în timp ce restul genomului este alcătuit din secvenţe necodante, care produc molecule de ARN active funcţional, cu roluri importante în reglarea homeostaziei tisulare şi a condiţiilor patofiziologice.

MicroARN (miRNA) sunt molecule de ARN mici (18-25 nucleotide), monocatenare, necodante, ce reglează post-transcripţional expresia genică prin inhibiţia translaţiei şi/sau promovarea degradării ARN mesager (ARNm), datorate împerecherii parţiale sau complete cu regiunile 3'-UTR ale ARNm [7, 8]. Împreună cu alte mecanisme moleculare, miRNA sunt reglatori genici post-transcripţionali puternici [9].

În nucleu, miRNA sunt transcrişi de către ARN polimeraza II ca pri-miRNA [10] şi procesaţi mai departe în pre-miRNA de către complexul microprocesor alcătuit din RNaza III Drosha împreună cu subunitatea sa reglatoare DGCR8 [11, 12]. Pre-miRNA sunt apoi transportaţi activ în citoplasmă de către Exportina-5 [13], unde sunt clivaţi în intermediari miRNA de tip duplex de către RNaza III Dicer [14]. Apoi,

catena miRNA conducătoare este selectată şi încărcată în complexul de silenţiere indus de miRNA (miRISC) ce reglează expresia genelor ţintă [14].

MiRNA pot fi exportaţi în spaţiul extracelular şi pot circula în fluxul sangvin asociaţi cu microparticule, exozomi, lipoproteine sau complexe proteice, putând acţiona ca mesageri extracelulari la distanţă mare [15-18].

MicroARN au roluri importante în patologie, fiind molecule de răspuns la stres şi având expresii modificate în cursul evoluţiei bolilor [19, 20]. Expresia celulară modificată a miRNA şi profilul alterat al miRNA circulanţi au fost asociate cu diferite tulburări, incluzând diferite tipuri de cancer, bolile neuro-degenerative, ateroscleroza, obezitatea, diabetul sau boala coronariană [21-25]. Profilul miRNA circulanţi poate reflecta modificarea expresiei tisulare sau a comunicării intercelulare, sugerând posibila utilizare a lor ca biomarkeri [26].

Evoluţia bolii aterosclerotice este influenţată de prezenţa factorilor de risc cum ar fi dislipidemia (în special hipercolesterolemia), hipertensiunea şi diabetul [27]. Studiile realizate până la ora actuală arată rolul major al microARN în modularea căilor metabolice implicate în aceste afecţiuni.

Prima parte a tezei de doctorat reprezintă **stadiul actual al cunoştinţelor** şi este structurată în 3 capitole ce abordează noţiuni teoretice despre ateroscleroza arterelor coronare, lipoproteinele serice şi biologia microARN.

Partea a doua a tezei prezintă **rezultatele originale obţinute în cadrul studiilor doctorale** şi este structurată pe 3 capitole, primele 2 reprezentând studii *in vivo* pe grupuri de pacienţi cu hiperlipidemie/hiperglicemie sau boli coronariene, iar al 3-lea capitol abordând în plus şi experimente *in vitro* pe modele de culturi celulare.

Astfel, lucrarea de faţă a avut 3 **obiective specifice**:

Obiectiv 1. Identificarea şi analiza microARN în seruri şi lipoproteine izolate de la pacienţi hiperlipidemici şi/sau hiperglicemici.

Obiectiv 2. Identificarea şi analiza microARN serici şi a celor asociaţi cu lipoproteine izolate de la pacienţi cu boală coronariană.

Obiectiv 3. Evaluarea modulării producţiei de microARN în macrofage umane în cultură de către serurile de la pacienţi cu boli coronariene.

Pentru atingerea acestor obiective am utilizat tehnici de biochimie, biologie moleculară şi biologie celulară, dintre care am adaptat **unele metode noi** în laborator. Astfel, am adaptat **metoda ELISA** pentru cuantificarea apolipoproteinelor A-I, B100 şi E şi a interleukinei 1β în serul pacienţilor investigaţi, pornind de la un kit ELISA de dezvoltare de metodă. Astfel, am redus consumul de reactivi şi de probă utilizaţi pentru măsurătoare.

Pentru **izolarea miRNA din lipoproteine**, am adaptat în laborator metoda descrisă de producător pentru izolarea miRNA cu kitul miRNeasy pentru ser/plasmă (Qiagen, Dusseldorf, Germany), utilizând 300 µL lipoproteine izolate (corespunzând la 120 µg proteină totală) şi mimic sintetic cel-miR-39 ca miRNA de referinţă pentru normalizarea conţinutului de miRNA în biofluide.

Am optimizat metoda descrisă de producător pentru **revers-transcrierea miRNA**, utilizând un amestec de amorse stem-loop specifice şi realizând o singură reacţie de revers-transcriere per probă pentru toate miRNA. Astfel, am reuşit să reducem semnificativ consumul de reactivi fără a compromite valoarea datelor obţinute.

Am pus la punct un **protocol nou de revers-transcriere dual a ARN** celular (izolat din macrofage umane în cultură), utilizând kit-ul de revers-transcriere High Capacity cDNA Reverse Transcription, amorse pentru revers-transcriere cu secvenţă aleatorie (*random primers*) şi un amestec de amorse TaqMan stem-loop miRNA-specifice (toate de la Applied Biosystems, Thermo Fisher Scientific), pe un sistem PCR Veriti. Astfel, am redus consumul de reactivi şi de probă, realizând o singură reacţie de revers-transcriere per probă, cu rezultate optime.

Am elaborat **modele de regresie logistică binară** pentru estimarea riscului de evenimente coronariene, folosind programul SPSS for Windows v21.

În **primul capitol** de rezultate originale, am detaliat un studiu pe un grup de pacienţi cu hiperlipidemie şi/sau hiperglicemie şi ne-am propus să evaluăm asocierea unui set de molecule de microARN din circulaţia sangvină cu hiperlipidemia şi/sau hiperglicemia. Studiul a cuprins 30 subiecţi recrutaţi din populaţia generală din Bucureşti, Romania, împărţiţi în patru grupuri: subiecţi sănătoşi (C), pacienţi cu hiperlipidemie (HL), pacienţi cu hiperglicemie (HG) şi hiperlipidemici-hiperglicemici (HLG), în funcţie de nivelurile serice de lipide şi glucoză *à jeun*.

Exista kituri comerciale pentru analiza distribuţiei microARN în celule, ţesuturi sau lichide biologice, ce utilizează amorse specifice pentru detectarea anumitor microARN implicaţi în diferite patologii (boli cardiovasculare, diabet, cancer etc.). Deoarece nu există un kit comercial specific care să conţină un set de miRNA pentru metabolismul lipidic şi al glucozei, am utilizat un PCR array specific pentru miRNA implicaţi în CVD (*Pathway-focused Human Cardiovascular Disease*) pentru determinarea profilului miRNA în seruri de la pacienţi hiperlipidemici (HL) şi/sau hiperglicemici (HLG). Selecţia miRNA pentru analiza individuală s-a bazat pe mărimea creşterii nivelului seric detectată în urma analizei profilului miRNA în ser şi pe datele disponibile în literatură. Astfel, am selectat şi analizat individual un set de opt miRNA (miR-122, miR-125a, miR-486, miR-92a, miR-146a, miR-10a, miR-21 şi miR-33a) în seruri de la pacienţi şi de la subiecţi sănătoşi.

Mai departe, am analizat corelaţiile dintre nivelurile miRNA selectaţi şi unii parametri lipidici şi inflamatori serici. Pentru a determina distribuţia acestor miRNA în clasele de lipoproteine, am izolat lipoproteine de joasă densitate (LDL) şi lipoproteine de înaltă densitate (HDL) din seruri hiperlipidemice şi/sau hiperglicemice şi am identificat prezenţa miRNA selectaţi.

Rezultatele arată că profilul miRNA din serurile HLG prezintă niveluri crescute de miR-122, miR-125a, miR-486 şi miR-92a. De asemenea, nivelurile miR-122, miR-125a, miR-146a, miR-10a, miR-21 şi miR-33a măsurate individual sunt crescute în serurile HL şi se corelează pozitiv cu principalii parametri lipidici şi inflamatori, în timp ce miR-92a şi miR-486 sunt crescuţi doar în serurile de la pacienţi HG. Toţi miRNA selectaţi sunt prezenţi predominant în HDL, doar miR-33a se regăseşte în cantităţi similare atât în HDL, cât şi în LDL. În plus, toţi miRNA analizaţi au niveluri crescute în HDL izolate din seruri hiperlipidemice (HL şi HLG).

Până la ora actuală, aceasta este primul studiu care identifică niveluri cuantificabile de miR-33a în LDL. Până la publicarea acestor rezultate (în *Molecular Biology Reports* şi *Annals of the Romanian Society of Cell Biology*), nu existau date în literatură care să descrie distribuţia miR-125a şi miR-10a circulanţi în serurile pacienţilor hiperlipidemici şi/sau hiperglicemici.

Aceste date originale au fost publicate în ***Molecular Biology Reports*** (revistă indexată ISI cu factor de impact 1,828, având în prezent **13 citări**) şi în ***Annals of the Romanian Society of Cell Biology*** (revistă indexată BDI, având în prezent **1 citare**) şi au fost comunicate la două manifestări ştiinţifice cu participare internaţională sub forma unei **comunicări orale** şi a unui **poster**.

Cel de-**al doilea capitol** de rezultate originale prezintă de asemenea un studiu clinic în care ne-am propus să identificăm miRNA din circulaţia sangvină asociaţi cu diferite subclase de lipoproteine izolate din serurile unor pacienţi în diferite stadii ale CAD: pacienţi cu angină stabilă (SA), pacienţi cu angină instabilă (UA) şi pacienţi la o lună după un infarct miocardic acut (MI) comparativ cu un grup de subiecţi sănătoşi. Grupul SA a fost considerat categorie CAD de referinţă, iar grupurile UA şi MI împreună au fost considerate ca grupuri de CAD vulnerabilă (categorie de risc). Toţi pacienţii au fost recrutaţi de la Clinica de Cardiologie a Spitalului Universitar de Urgenţă Elias, Bucureşti. Subiecţii control au fost donatori sănătoşi de la Centrul de Transfuzie Sangvină, Bucureşti, fără factori de risc cardiovascular sau alte boli în evidenţă (conform istoricului medical, examinării clinice şi testelor de laborator).

Un scop adiţional a fost determinarea miRNA specifici care, împreună cu un set de parametri lipidici cunoscuţi, sunt capabili să prezică vulnerabilitatea pacientului CAD. În acest scop, am izolat lipoproteine de densitate intermediară (IDL), LDL şi HDL din seruri de la pacienţi CAD şi am investigat prezenţa miRNA şi distribuţia lor în subclasele specifice de lipoproteine.

Date publicate anterior arată rolul miRNA în evoluţia CVD şi importanţa utilizării lor ca instrumente de diagnostic [28]. Până la ora actuală, puţine studii au investigat asocierea miRNA cu lipoproteinele circulante şi implicarea lor în evoluţia CAD [18, 24, 29].

Datele obţinute în acest studiu arată că miR-486, miR-92a, miR-122 au cele mai mari niveluri în serurile pacienţilor CAD versus serurile subiecţilor control, dar nivelurile lor serice individuale nu diferă din punct de vedere statistic între grupurile CAD. Nivelurile miR-486 şi miR-92a considerate împreună cu nivelurile de HDL-C, apolipoproteine şi cu activitatea PON1 pot discrimina între pacienţii CAD stabili şi cei vulnerabili, cu un nivel de predicţie de circa 85%.

Datele noastre arată că toţi miRNA selectaţi sunt asociaţi în principal cu HDL, fiind în acord şi extinzând studii ale altor grupuri, recent publicate [15, 18]. Astfel, miR-486, miR-92a, miR-122, miR-125a şi miR-146a sunt asociaţi în principal cu HDL serice şi de zece ori mai puţin cu IDL şi LDL. În plus, miR-486 şi miR-92a au cele mai mari niveluri în HDL izolate de la pacienţi CAD vulnerabili (UA şi MI) versus SA şi distribuţia lor diferă între subfracţiile de HDL, miR-486 predominând în HDL_2, în timp ce miR-92a predomină în HDL_3.

Experimentele noastre arată o distribuţie preferenţială a miRNA în subpopulaţiile HDL (HDL_2 şi HDL_3), nivelurile de miR-486 şi miR-92a putând discrimina între pacienţii CAD stabili şi vulnerabili. Astfel, rezultatele noastre arată o creştere specifică a nivelurilor miR-486 în HDL_2 şi a miR-92a în HDL_3, în special în cele izolate din serurile pacienţilor CAD vulnerabili (pacienţii UA şi MI) comparativ cu pacienţi SA. Aceste date sunt mai departe confirmate de rezultatele care arată că nivelurile serice ale miR-486 şi miR-92a pot estima riscul de CAD vulnerabilă într-un model de regresie logistică binară corectat pentru nivelurile serice de lipide, apolipoproteine şi activitatea enzimelor asociate cu HDL.

Aceste date originale au fost publicate în ***PLoS ONE*** (revistă indexată ISI cu factor de impact 2,806, având în prezent **15 citări**) şi au fost comunicate la 9 manifestări ştiinţifice internaţionale sub forma a **3 comunicări orale** şi **7 postere** şi la 1 manifestare ştiinţifică naţională sub formă de **poster**. Rezumatele a 5 postere au fost publicate în 4 reviste indexate ISI (*FEBS Journal*, *European Heart Journal*, *Cardiovascular Research x2*) şi 1 revistă BDI (*Romanian Journal of Cardiology*).

În cel de-**al treilea capitol** de rezultate originale, am evaluat nivelurile a şase miRNA (miR-223, miR-92a, miR-486, miR-122, miR-125a şi miR-146a) în seruri şi HDL de la pacienţi cu SA, pacienţi cu ACS şi subiecţi sănătoşi. Toţi pacienţii CAD au fost recrutaţi de la Clinica de Cardiologie a Spitalului Universitar de Urgenţă Elias, Bucureşti, iar subiecţii control au fost donatori sănătoşi recrutaţi din personalul Institutului de Biologie şi Patologie Celulară „Nicolae Simionescu” şi al Spitalului Elias, neavând boli cardiovasculare în antecedente sau alte afecţiuni cunoscute.

Este general acceptat că hiperglicemia este un factor accelerant în evoluţia CAD [30], de aceea am urmărit să investigăm efectul concentraţiilor crescute de glucoză asupra macrofagelor umane în cultură, mai exact asupra expresiei genice a proteinelor maşinăriei de procesare a miRNA (Dicer, Drosha, DGCR8) şi asupra producţiei miRNA analizaţi.

Datele obţinute în acest studiu privind efectul hiperglicemiei asupra miRNA arată că în serurile ACS hiperglicemice, nivelurile miR-223, miR-92a, miR-486, miR-122, miR-125a şi miR-146a sunt crescute comparativ cu serurile ACS normoglicemice. De asemenea, efectul hiperglicemiei se observă şi asupra lipoproteinelor, în HDL izolate din seruri ACS hiperglicemice, nivelurile miR-223, miR-92a şi miR-486 sunt crescute comparativ cu seruri normoglicemice şi sunt semnificativ diferite între pacienţii ACS şi SA.

În studiul nostru, corelaţiile parametrice arată că miR-92a şi miR-486 se corelează negativ cu doi factori de risc pentru CAD: LDL mici şi dense (exprimate ca raportul LDL-C/apoB-100) şi HDL disfuncţional (exprimat ca raportul activitatea PON1/apoA-I). Aceasta sugerează că atunci când LDL mici şi dense şi HDL disfuncţional coexistă, nivelurile miR-92a şi miR-486 cresc, completând rezultatele noastre anterioare care arată o asociere preferenţială a miR-92a şi miR-486 la pacienţii CAD vulnerabili. De asemenea, analiza logistică a parametrilor specifici ai pacienţilor a arătat că nivelurile serice de miRNA (în special miR-92a şi miR-486), împreună cu obezitatea, hipertensiunea, hiperglicemia şi disfuncţionalitatea HDL, au potenţialul de a prezice riscul de producere a unor evenimente cardiovasculare la pacienţi CAD.

În acest capitol arătăm, de asemenea, că în macrofage umane expuse în cultură la seruri izolate de la pacienţi normoglicemici, serurile ACS induc creşterea expresiei genice a Drosha, DGCR8 şi Dicer (proteine implicate în biogeneza miRNA) şi a producţiei miR-223, miR-92a, miR-486, miR-125a şi miR-146a comparativ cu serurile SA, iar concentraţiile crescute de glucoză potenţează efectele observate, mai ales în cazul serurilor ACS. Din informaţiile pe care le avem până la acest moment, acesta este primul studiu care evaluează efectele serurilor de la pacienţi CAD asupra expresiei miRNA şi a componentelor maşinăriei de procesare a acestora în macrofage umane.

Adăugarea glucozei în serurile normoglicemice (pentru a mima concentraţiile crescute existente în serurile hiperglicemice) induce o creştere atât a nivelurilor intracelulare de miRNA (miR-125a, miR-486, miR-92a, miR-146a, miR-223), cât şi a expresiei unor proteine din maşinăria de procesare a miRNA (Drosha, DGCR8 şi Dicer).

Din informaţiile pe care le avem până la acest moment, acestea sunt primele date care arată efectul concentraţiilor crescute de glucoză asupra producţiei miRNA în macrofage umane. Creşterea producţiei miRNA observată în macrofage în cultura este în acord cu nivelurile crescute ale miRNA specifice în seruri.

Aceste date originale au fost publicate în ***PLoS ONE*** (revistă indexată ISI cu factor de impact 2,806, având în prezent **3 citări**) şi au fost comunicate la 3 manifestări ştiinţifice internaţionale sub forma a **2 postere** şi la 1 manifestare ştiinţifică naţională sub formă de **poster**. Rezumatul unui poster a fost publicat în o revistă indexată ISI (*Atherosclerosis*).

În urma rezultatelor obţinute în studiile cu pacienţi şi prin experimentele *in vitro* utilizând macrofage umane în cultură, se pot contura următoarele **concluzii generale**:

1. Nivelurile miR-122, miR-125a, miR-486, miR-92a, miR-146a, miR-10a, miR-21 şi miR-33a circulanţi sunt corelate cu lipidele serice, cu nivelurile de CRP şi IL-1β în serurile pacienţilor hiperlipidemici şi/sau hiperglicemici.
2. Nivelurile miR-125a şi miR-146a circulanţi sunt asociate cu hiperglicemia serică.
3. MiR-122, miR-125a, miR-486, miR-92a, miR-146a, miR-10a şi miR-21 circulanţi sunt asociaţi în principal cu HDL, iar miR-33a este asociat şi cu LDL.
4. Nivelurile serice ale miR-486 şi miR-92a împreună cu nivelurile apoA-I, apoE, cu activitatea PON1 şi cu raportul HDL-C/LDL-C (într-un model de regresie logistică binară) pot fi utilizaţi ca markeri adiţionali pentru diagnosticul CAD vulnerabilă.
5. MiR-486 şi miR-92a se asociază preferenţial cu subpopulaţiile HDL (miR-486 cu HDL_2 şi miR-92a cu HDL_3) şi nivelurile lor discriminează între pacienţii CAD vulnerabili (UA şi MI) şi cei cu angină stabilă.
6. Concentraţiile serice crescute de glucoză se corelează cu nivelurile crescute de miR-223, miR-92a, miR-486 în seruri şi HDL izolate de la pacienţi CAD, aceşti miRNA asociaţi cu HDL fiind capabili să discrimineze între pacienţii ACS şi SA.
7. Expunerea macrofagelor umane în cultură la seruri ACS comparativ cu seruri SA determină creşterea producţiei intracelulare a miR-223, miR-92a, miR-486, miR-125a şi miR-146a prin creşterea expresiei Drosha, DGCR8 şi Dicer, acest efect fiind augmentat de creşterea concentraţiei de glucoză.

Perspective:

Pe baza rezultatelor originale obţinute în cadrul tezei de doctorat, dorim să continuăm studiul microARN prin investigarea funcţionalităţii miR-486 şi miR-92a, utilizând metode *in silico*, *in vitro* şi *in vivo*. Astfel, vom determina genele ţintă ale miR-486 şi miR-92a prin bioinformatică, vom testa ţintirea directă de către mimici ai miRNA a genelor inserate în plasmide şi vom evalua efectele terapiei cu inhibitori pentru miRNA la hamsterul hiperlipidemic.

De asemenea, dorim să analizăm distribuţia microARN în fragmente vasculare recoltate de la pacienţi cu boli cardiovasculare şi să o corelăm cu nivelurile lor circulante şi cu gravitatea bolii.

Institute of Cellular Biology and Pathology
"Nicolae Simionescu"
8, B.P. Hasdeu Street, POB 35 – 14, Bucharest, Romania
Phone: (+4021) 319.45.18; 319.45.20; www.icbp.ro

RULES OF ORGANISATION AND OPERATION

„NICOLAE SIMIONESCU" INSTITUTE OF CELL BIOLOGY AND PATHOLOGY ROMANIAN ACADEMY

CHAPTER I
General framework.....3

CHAPTER II
Subject matter.....4

CHAPTER III
Organisation of the Institute of Cell Biology and Pathology "Nicolae Simionescu".....4

CHAPTER IV
Final provisions.....9

CHAPTER I
General Framework

Article 1
The Institute of Cell Biology and Pathology was established on the 15th of April 1978, according to Decree no.152; from its establishment until 1990 the Institute was under the Ministry of Education and Training, after which it became part of the Romanian Academy.
The official name of the Institute is: Institute of Cell Biology and Pathology "Nicolae Simionescu" (hereafter, ICBP "NS").

Article 2
(1) ICBP "NS" is a Romanian legal entity of public interest and operates in accordance with the regulations governing the activity of the research institutes of the Romanian Academy (the tutelary forum), as well as its own regulations adopted within the limits conferred by law.

(2) ICBP "NS" is coordinated by the Biological Sciences Section of the Romanian Academy, and the economic-financial activity is coordinated and controlled by the administrative apparatus of the Romanian Academy, according to the Statute of the Romanian Academy, art. 43, para. 1-5.

Art. 3
(1) ICBP "NS" has its headquarters in Romania, Bucharest, 8 B.P. Hasdeu Street, sector 5, postal code 050568. In the individual land register no. 47925 of the Municipality of Bucharest, sector 5, ICBP "NS" has cadastral no. 14962.

Art. 4
(1) ICBP "NS" administers the funds received from the state budget, through the guardian body, the Romanian Academy, under the conditions of the law.

(2) The own income from contracts with funding from research projects and other contracts with various beneficiaries are administered in compliance with the legal provisions in force and in accordance with the Statute of the Romanian Academy, art. 43, para. 4, with the approval of the Director and/or the Scientific Council, as the case may be.

CHAPTER II
Subject matter

Art. 5 ICBP "NS" has the following objectives:
a. Basic biomedical research and transfer of results to the clinic;
b. to ensure the specialisation and further training of researchers in the field of cell biology and pathology, through post-graduate courses, specialisation traineeships, doctoral and other forms;
c. supporting the teaching process in the disciplines of cell biology and pathology in which students of the faculties of biology, medicine, pharmacy, chemistry, physics, etc. are trained.
d. promotion of modern cell biology and pathology in Romania;
e. to increase international scientific exchanges

Art. 6 Research is carried out within the framework of research programmes and projects approved by the Scientific Council and approved by the Biological Sciences Section of the Romanian Academy, in accordance with the provisions of the Statute of the Romanian Academy, art. 15, para. 5, as well as on the basis of contracts with public partners interested in the research of processes within the scope of activity of the Institute.
Art. 7 Within the framework of its activity, ICBP "NS" collaborates with research institutes, higher education institutions and other units interested in scientific research and application of results in the field of cell biology and pathology. The Institute also collaborates, on the basis of agreements and understandings, with specialized institutions abroad, with international bodies in the field, as well as with prestigious scientific personalities in the field.

CHAPTER III

Organisation of the "Nicolae Simionescu" Institute of Cell Biology and Pathology

Art.8 The organisational structure of the ICBP "NS" comprises the following hierarchical levels:

Scientific Council

Director

Deputy Director,

Scientific Secretary

Research Department

Administrative department

Art. 9 The organisational structure of the ICBP "NS" comprises

A) Research Compartment which includes the departments and laboratories:

1. LIPIDOMICS Department
2. PROTEOMICS Department
3. Department of PATHOPHYSIOLOGY AND CELL PHARMACOLOGY
4. Department of BIOPATOLOGY AND THERAPY OF INFLAMMATION
5. Department of FUNCTIONAL GENOMICS
6. Department of GENE REGULATION AND MOLECULAR THERAPY
7. Department of STEM CELL BIOPATOLOGY,
8. Department of CELL AND TISSUE ENGINEERING and EXPERIMENTAL MODELING PLATFORM

B) Economic-Administrative Department comprising:

1. Human Resources Department, Financial-Accounting Department, Secretariat, Library, Central Store;
2. Technical Service which includes the Technical Administrative Department and the Protection and Security Department;
3. Procurement Department

Art. 10 Powers of the management by hierarchical levels: Scientific Council

(1) The Scientific Council is the scientific management structure of the ICBP "NS", appointed according to art. 46 and 47 of the Statute of the Romanian Academy.

(2) The Scientific Council consists of the President (Director of the Institute), the Deputy Scientific Director, the Scientific Secretary and a number of members. The members of the Romanian Academy working in the Institute, the Deputy Director, the Scientific Secretary and the persons in charge of the research departments/laboratories are ex officio members of the Scientific Council.

(3) The Scientific Council has mainly the following tasks:

3.1 it carries out its activity according to Art. 47 of the Statute of the Romanian Academy and the laws in force;

3.2 it analyzes and approves the research works carried out in the Institute, presenting, when necessary, improvement measures;

3.3 approves the results of the competitions for filling positions in the Institute and submits them for approval to the Biological Sciences Section of the Romanian Academy;

3.4 to set the dates and themes of the scientific sessions organised by ICBP "NS";

3.5 approves/approves the documents elaborated within the PhD, according to the SCOSAAR (School of Advanced Studies of the Romanian Academy) regulations

3.6 annually reviews and approves the continuation of the activity of the scientific researchers I who wish to continue working in the institute after reaching retirement age;

3.7 ensures the regular holding of scientific seminars and progress reports on research topics;

3.8 prepares the documents requested by the Romanian Academy;

3.9 together with the Ethics Committee, supervises the observance of ethical rules by the researchers of the ICBP "NS";

3.10 decides on the participation of researchers from the Institute in congresses, round tables, conferences, courses abroad;

3.11 takes all necessary measures for the good organization and safe conduct of the activity, for the permanent supervision of the equipment and installations, of all the rules of operation, maintenance, repairs, maintenance of order and discipline, organization of the systematic control of the duties of the employees and holding accountable those who violate the obligations of the service;

3.12 take measures to improve working conditions, ensure the conditions of work protection and compliance with the health and hygiene rules according to the legislation in force;

3.13 establishes individual performance objectives and the criteria for evaluating their achievement;
3.14 performs any other tasks related to the scientific activity of the ICBP "NS".
The proceedings of the meetings of the Scientific Council shall be recorded in the relevant minutes.

Art. 11 Duties of the management by hierarchical levels: Director
(1) represent the ICBP "NS" in its relations with other institutions in the country and abroad;
(2) is a tertiary authorising officer, according to the law;
(3) elaborates in collaboration with the Deputy Director, the Scientific Secretary and the heads of scientific departments the scientific research plan of the Institute, submits it to the Scientific Council for discussion and approval by the Biological Sciences Section of the Romanian Academy;
(4) ensures the scientific coordination of the activity of the research departments/laboratories, organizes and controls the activity of the Institute in order to ensure the optimal realization of the research plan;
(5) to ensure the publication and exploitation of scientific research results;
(6) performs the duties incumbent upon him/her and is responsible for the entire activity of the ICBP "NS", according to the law and art. 45 of the Statute of the Romanian Academy.

Art. 12 Duties of the management on hierarchical levels: Deputy Director
(1) shall be appointed by competition for a period of 4 years, according to the provisions of art. 44 para. 1 of the Statute of the Romanian Academy and Law 319/2003. He/she is subordinate to the Director;
(2) The duties of the Deputy Scientific Director are the following:
a.support the Director of the ICBP "NS" in the performance of all his/her duties;
b.to coordinate the elaboration of draft research programmes, monitoring their implementation;
c. to guide and supervise the realization of the scientific events of the ICBP "NS", supporting the Director in ensuring the relations of the ICBP "NS" with other institutions in the country and abroad;
d. to ensure the effective exploitation of the results of scientific research and the collaboration of the ICBP "NS" with other institutions;
e. to follow up the implementation of ICBP "NS" research contracts;
f. to carry out other management activities based on the delegation of tasks, powers and responsibilities by the Director of the ICBP "NS".

Art. 13 Monitoring Commission

(1) In order to monitor, coordinate and methodologically guide the implementation and development of the internal managerial control system, the Director of ICBP "NS"constitutes, by internal decision act, a structure with attributions in this sense, called the Monitoring Commission.

(2) The Monitoring Commission includes the Coordinators of the departments/laboratories included in the first management level of the organizational structure of ICBP"NS", with the exception of the internal public audit department.

(3) The Monitoring Commission is coordinated by a President, who can be the head of the entity or another person with authority, delegated by him and assisted by a technical secretariat.

(4) The way of organization and work of the Monitoring Commission is under the responsibility of its President and is established according to the volume and complexity of the processes and activities, based on the Commission's Organization and Operation Regulation, which is updated whenever is the case.

(5) The President of the Monitoring Commission ensures the management of the meetings, according to the agenda, and approves the minutes of the meetings and, as the case may be, their decisions. Depending on the theme of the agenda of the meetings, at the request of the President of the Monitoring Commission, other persons may also participate as guests.

(6) The Monitoring Commission coordinates the process of updating the general and specific objectives, the procedural activities, the risk management process, the performance monitoring system, the status of the procedures and the monitoring and reporting system, respectively information to the manager public entity.

Art. 14 Internal Management Control System Development Programme

(1) In order to strengthen a system of managerial internal control, the Monitoring Commission shall draw up the Programme for the Development of the System of Managerial Internal Control, referred to as the Development Programme, which shall be updated annually at the level of the ICBP "NS".

(2) The Development Programme shall include the objectives of the public entity in the field of managerial internal control, according to the stage of its implementation and development, and for each standard of managerial internal control, activities, responsible persons and deadlines, as well as other relevant elements in the implementation and development of the managerial internal control system shall be established.

(3) The Development Programme shall also highlight professional development actions in the field of the system of managerial internal control, both for persons with managerial and executive functions, through courses organised in accordance with the relevant legislative regulations.

Article 15 Risk management

(1) The risk management process shall be under the responsibility of the Chairman of the Monitoring Commission, organised according to the size, complexity and specific environment of the ICBP "NS".
(2) In order to ensure effective risk management at all levels of the ICBP "NS", the coordinators of the compartments/laboratories at the first management level of the organisational structure shall appoint a risk officer at their level.
(3) Risk Officers shall advise the staff of the compartments and assist their managers in the risk management process.
(4) Risks related to objectives and/or activities shall be identified and assessed at the level of each compartment in accordance with the minimum elements of the Risk Register; significant risks shall be centralised at the level of the Monitoring Committee in the Risk Register of the ICBP "NS".
(5) The Monitoring Commission analyses and prioritises significant risks, which may affect the achievement of the objectives of the ICBP "NS", by establishing the risk profile and risk tolerance limit, annually, approved by the management of the ICBP "NS".
(6) The Technical Secretariat of the Monitoring Commission, based on the Risk Register of the ICBP "NS", proposes the risk profile and risk tolerance limit which are reviewed and endorsed in the Commission meeting and approved by the Director of the ICBP "NS",.
(7) The coordinator of the department/laboratory submits the control measures for significant risks to the Technical Secretariat of the Monitoring Commission, which annually draws up the Plan for the implementation of control measures for significant risks at the level of the ICBP "NS"; the plan is reviewed by the Monitoring Commission and approved by the Director of the ICBP "NS".
(8) The Technical Secretariat of the Monitoring Commission forwards the approved Plan of Measures to the departments responsible for significant risk management for implementation.
(9) The Technical Secretariat of the Monitoring Commission shall, on the basis of the annual reports of the coordinators of the departments/laboratories at the first management level on the conduct of the risk management and performance monitoring process, prepare a report to the Director of the ICBP "NS", approved by the Chairperson of the Monitoring Commission, on the conduct of the risk management and performance monitoring process at the ICBP "NS".

(10) The briefing shall include an analysis of the risks identified and managed at department/laboratory level and the monitoring of objectives and activities through performance indicators at the level of the ICBP "NS".
(11) The management of the ICBP "NS" shall ensure that documented procedures, i.e. system procedures and operational procedures, for the processes and activities carried out within the CPBC "NS" are developed and communicated to its staff.
(12) In order to ensure the regular, effective, economical and efficient achievement of the objectives of the ICBP "NS", the departments/laboratories shall draw up documented procedures under the coordination of the Monitoring Commission.
(13) The Technical Secretariat of the Monitoring Commission shall review the procedure in terms of compliance with the minimum structure laid down in the Documented Procedure.
(14) Documented procedures shall be signed by the persons responsible for procedural activities when drawn up, by the department/laboratory coordinator when checked, by the Chairman of the Monitoring Commission when endorsed and approved by the Director of the ICBP "NS" or, where appropriate, in accordance with the procedure laid down at ICBP "NS" level.
(15) Depending on the specifics and complexity of ICBP "NS" activities, including internal regulations, ICBP "NS" customizes its procedures in accordance with its own system procedure, necessarily based on the minimum structure provided for in the Documented Procedure.

Art. 16 The attributions of management by hierarchical levels: the Scientific Secretary

(1) is appointed through competition for a period of 4 years, in relation to the provisions of art. 44 para. 1 of the Statute of the Romanian Academy and of Law 319/2003. He is subordinate to the Director of ICBP "NS";
(2) The Scientific Secretary has the following duties:
a. provides administrative services collateral to the doctoral studies carried out by ICBP "NS", the direct sub-coordination of the Director of ICBP "NS", with the approval of SCOSAAR and the Department of Life, Medical and Agricultural Sciences of SCOSAAR;
b. is responsible for the effective implementation of the scientific events organized by ICBP "NS";
c. elaborates the activity reports of the ICBP "NS", participating in the finalization, together with the Director, of the research program projects;
d. supports the Director in coordinating the editorial teams of the ICBP "NS" publications, when they are produced;
e. pursues the effective realization of the valorization of scientific research from ICBP "NS";

f. ensure the creation of the database of the Scientific Council of ICBP "NS".

Art. 17 Attributions of management by hierarchical levels: Chief Accountant

(1) He is appointed through competition and is appointed by the Director, under the conditions of Law 82/1991 - the updated Accounting Law. He is subordinate to the ICBP Director "NS".
(2) It mainly has the following attributions:
a. elaborates the project of the income and expenses budget, following, after approval, its quarterly and annual implementation;
b. manages, organizes and carries out the financial management and accounting activities, following the compliance with the legislation in force;
c. ensures the management and management of the patrimony of ICBP"NS";
d. monitors the progress of collection operations, according to the laws in force;
e. ensures the management, according to laws and contracts, of extrabudgetary revenues;
f. provide other tasks according to the Director's decisions;
g. the position of Chief Accountant is held in relation to the provisions of Law 82/1991 - the updated Accounting Law, by a graduate with higher economic studies.

Art. 18 The attributions of management on hierarchical levels: Head of the Technical Service
(1) He is appointed through competition and is appointed by the Director, according to the legislation in force. He is subordinate to the Deputy Director of ICBP "NS".
(2) It mainly has the following attributions:
a. organizes, coordinates and controls the activity of the Technical Service;
b. elaborates and proposes for approval the ICBP "NS" policies regarding the technical-administrative activity;
c. elaborates the project of the procurement plan for the Technical Service;
d. coordinates the timely commissioning of the newly purchased equipment;
e. executes any other provisions given by the Director in achieving the short, medium and long term strategies of ICBP "NS", within the limits of compliance with the legal basis.
Art. 19 Attributions of heads of organizational structures: Department/Laboratory Coordinator
(1) Ensures the coordination of a research department/laboratory for the realization of projects related to field-specific research programs, having the following attributions:
a. elaborates the projects of the research programs, monitors the realization of the research works included in the research program of ICBP "NS", ensuring the overall coordination of their content;
b. supports and guides researchers in their professional specialization, in improving the working methodology and in the proper operation of the equipment;
c. supports researchers for the exploitation of their results and for the integration of data in the national and international scientific circuit;
d. prepares the research reports of the department/laboratory;
e. prepares the annual evaluations of researchers in the department/laboratory;
f. carries out other tasks received from the management of ICBP "NS".
(2) The Department/Laboratory coordinator is appointed by the Director, after consulting the Scientific Council.

It is subordinate to the Scientific Council, and through it, to the Director.

Art. 20 In the administrative sector, the head of department/office ensures the smooth functioning of the department/office he leads, coordinates the activity of the subordinate staff, is responsible to the ICBP "NS" management for the activity of the department/office. He is appointed by competition according to the legislation in force and is subordinate to the leadership of ICBP "NS".

Art. 21 Purpose and definition of internal managerial control standards

(1) Internal managerial control standards define a minimum of general management requirements that all public entities must follow.

(2) The purpose of control standards is to create a uniform and coherent internal managerial control model that allows comparisons between entities of the same kind or within the same entity, at different times, and makes it possible to highlight the entity's results and its evolution .

(3) The establishment of the internal managerial control system is the responsibility of the management of each public entity and must be based on the internal control standards promoted by the General Secretariat of the Government, pursuant to the law. Their formulation as general as possible is necessary to enable all managers to apply them, despite the significant differences between different public entities. Internal managerial control systems must be developed taking into account the specific legal, organizational, personnel, financing, etc. of each individual public entity.

(4) The standards are grouped into five components of internal managerial control:

– control environment - groups issues related to organization, human resources management, ethics, deontology and integrity;

– performance and risk management - refers to management issues related to goal setting, planning (multiannual planning), programming (management plan), performance (performance monitoring) and risk management;

– control activities - the standards grouped in this component focus on the elaboration of procedures, continuity of processes and activities, separation of duties, supervision;

– information and communication - in this section are grouped the problems related to the creation of an adequate information system and a system of reports regarding the execution of the management plan, the budget, the use of resources, as well as the management of documents;

- evaluation and audit - the issue covered by this group of standards concerns the development of the capacity to evaluate internal managerial control, in order to ensure the continuity of its improvement process.

(5) Each control standard is structured as follows:

– description of the standard - presents the defining features of the specific domain to which the standard refers, domain fixed by its title;

– general requirements - present the determining directions in which to act in order to comply with the standard;

- main references - specify the representative normative acts, which include regulations applicable to the standard, but not exhaustive.

Art. 22 List of internal managerial control standards at public entities

a) The control environment

– Standard 1 - Ethics and integrity

– Standard 2 - Duties, functions, tasks
– Standard 3 - Competence, performance
– Standard 4 - Organizational structure
b) Performance and risk management
– Standard 5 - Objectives
– Standard 6 - Planning
– Standard 7 - Performance monitoring
– Standard 8 - Risk management
c) Control activities
– Standard 9 - Procedures
– Standard 10 - Supervision
– Standard 11 - Business continuity
d) Information and communication
– Standard 12 - Information and communication
– Standard 13 - Document management
– Standard 14 - Accounting and financial reporting
e) Evaluation and audit
– Standard 15 - Evaluation of the internal managerial control system
– Standard 16 - Internal audit

Standard 1-Ethics and integrity.
(1) The management and employees of ICBP "NS" know and support the ethical values and values, ICBP"NS" respects and applies the regulations regarding ethics, integrity, avoiding conflicts of interest, preventing and reporting fraud, acts of corruption and reporting irregularities .
(2) The management of ICBP "NS" supports and promotes, through its decisions and the power of personal example, ethical values, personal and professional integrity of employees.
3. The leadership of ICBP "NS" adopts a code of conduct, develops and implements policies and procedures regarding integrity, ethical values, avoiding conflicts of interest, preventing and reporting fraud, acts of corruption and reporting irregularities.
4. The leadership of ICBP "NS" facilitates the open communication by employees of their concerns in matters of ethics and integrity, by appointing an ethics advisor to monitor compliance with the rules of conduct at the entity level.
5. The action of reporting irregularities by employees must be transparent and must be seen as the exercise of a professional duty.
6. Employees who report irregularities of which, directly or indirectly, they are aware are protected against any discrimination, and managers have the obligation to undertake appropriate investigations, in order to elucidate what has been reported and to take, if necessary, the necessary measures.
7. The management and employees of ICBP "NS" have a constructive approach to internal managerial control, whose operation they support permanently.
8. The declaration of assets, interests and goods received free of charge is carried out by all concerned factors, in accordance with the legal provisions.

Standard 2- Duties, functions, tasks.

1. The management of ICBP "NS" ensures the preparation and updating of the document regarding the mission of ICBP "NS", internal regulations and job descriptions, which it communicates to employees.
2. The regulation of organization and operation of the ICBP "NS" includes in an integral manner, as the case may be, general regulations, the role and functions of the ICBP "NS", the main attributions, the organizational structure, the functional relations, competences and attributions of the departments/laboratories; the regulation is published on the website of the ICBP "NS", if possible.
3. Each employee must know the mission and vision, the general and specific objectives of ICBP "NS" and of the department/laboratory of which he is a part, his role within the department/laboratory, established by the job description, as well as the duties of the position he occupies .
4. The coordinators of the ICBP "NS" departments/laboratories have the obligation to draw up and update, whenever necessary, job descriptions for subordinate staff.
5. The tasks/assignments of the position must be clearly formulated and closely related to the specific objectives and attributions of the department/laboratory.
6. The coordinators of the ICBP "NS" departments/laboratories must identify the new and/or highly complex tasks assigned to the employees and support them in achieving them, offering them a concrete work vision.
7. The ICBP "NS" coordinator orders the identification of sensitive functions based on risk factors, their centralization at the ICBP "NS" level and the establishment of an appropriate policy for their management by developing measures, so that the negative effects on the activities carried out within the ICBP "NS" should be minimal.

Standard 3- Competence and performance

1. The management of ICBP "NS" ensures that positions are filled by competent persons, to whom they entrust tasks according to their skills, and ensures conditions for improving the professional training of employees.
2. The professional performances of employees are evaluated annually in relation to the objectives of the position.
3. The management of ICBP "NS" and the employees have the knowledge, skills and experience that make it possible to carry out the tasks/assignments efficiently and effectively, as well as the good understanding and fulfillment of the responsibilities related to internal managerial control.
4. The competence of the employees and the entrusted tasks must be in permanent balance, to ensure which the management of ICBP "NS" acts by:

– defining the knowledge and skills required for each job;

- conducting recruitment interviews, based on a predetermined evaluation document;

– identifying professional training needs and establishing professional training requirements in the context of the annual evaluation of employees, as well as tracking their career evolution; the training needs identified are correlated with the results from the individual professional performance evaluation reports/sheets.

5. The professional performances of the employees are evaluated at least once a year in relation to the individual annual objectives and are discussed with them by the evaluator.

6. The managers of ICBP "NS" ensure that each employee participates in professional training courses in his field of competence, according to the legislation in the field.

Standard 4- Organizational structure

1. The director of ICBP "NS" defines the organizational structure, competencies, responsibilities, tasks, organizational relationships and communicates the specific documents of the organizational structure to the employees.
2. The director of ICBP "NS" establishes, in writing, the limits of the powers and responsibilities he delegates, in accordance with legal requirements.
3. The organizational structure must be established in accordance with the mission and purpose of ICBP "NS", so that it supports the decision-making process through an adequate delegation of responsibilities and serves to achieve the established objectives in conditions of efficiency, effectiveness and economy.
4. Pursuant to the normative act on the organization and operation of ICBP "NS", the Director of ICBP "NS" approves the organizational structure: departments/laboratories, general directorates, departments, services, offices, compartments.
5. Staffing with management staff and execution staff of the departments/laboratories can be found in the entity's job description and is carried out in compliance with the concordance between the nature of the positions and the professional and managerial skills necessary to fulfill the tasks of the employees.
6. Competence, responsibility, task and obligation to report are attributes associated with the position; they must be well defined, clear, coherent and reflect the elements considered for achieving the ICBP "NS" objectives.
7. The leadership of ICBP"NS" periodically analyzes the degree of adaptability of the organizational structure to the changes made inside and/or outside ICBP "NS".
8. In ICBP "NS", the delegation of duties is carried out through the organization and operation regulations, job descriptions and through express orders/decisions to carry out certain operations and responsibilities.
9. The delegation is conditioned mainly by the potential and degree of workload of the ICBP "NS" management and the employees involved.
10. The act of delegation of duties and powers is compliant when:
– respects the ratio between the complexity of the delegated tasks/assignments and the knowledge, experience and ability necessary to perform the delegated act of authority;
- the completion deadlines and specific criteria for the successful performance of delegated tasks/assignments are specified in its contents;
– all information on the responsibility that will be entrusted is provided by the Director;
- it is confirmed, by signature, by the employee to whom the tasks/attributions have been delegated.
11. The delegated employee is fully responsible for the performance of the task, and the manager who delegated maintains the final responsibility for its performance in front of his superiors.

Standard 5- Objectives

1. The management of ICBP "NS" defines the general objectives, related to the entity's goals, information reliability, compliance with laws, regulations and internal policies, as well as specific objectives and communicates them, as appropriate, to all employees and interested third parties.

2. The objectives of the ICBP”NS” must be clearly formulated, in a way that allows monitoring their fulfillment and be updated whenever necessary.
3. The management of ICBP”NS” establishes the general objectives so that they are correlated with the mission and goals of ICBP”NS” and with respect to the principles of economy, efficiency and effectiveness.
4. The leadership of ICBP”NS” transposes the general objectives into specific objectives and into expected results for each activity and communicates them to the employees.
5. The specific objectives must be defined in such a way as to respond to the package of "SMART" requirements (specific, measurable, appropriate, realistic, with a deadline).
6. Establishing the objectives is within the competence of the ICBP”NS” management, and the responsibility for their achievement lies with both the management and the employees.
7. The establishment of the objectives is based on the formulation of hypotheses/premises, correlated with the provisions of the normative act on the organization and operation of the ICBP"NS". Performance indicators are attached to specific objectives and activities and are communicated to employees by the Director.
8. The management of ICBP"NS" updates/reevaluates the objectives whenever it notices a change in the assumptions/premises that were the basis for setting them. The management of ICBP”NS” draws up plans or other planning documents that align the activities necessary to achieve all the objectives set with the maximum resources possible to allocate, establish deadlines and responsible persons, so that the risks likely to affect the achievement of ICBP"NS" 's objectives should be minimal.

Standard 6- Planning
1. The management of ICBP”NS” draws up plans or other planning documents that align the activities necessary to achieve all the objectives set with the maximum resources possible to allocate, establish deadlines and responsible persons, so that the risks likely to affect the achievement ICBP”NS” objectives to be minimal.
2. The leadership of ICBP”NS” elaborates, as appropriate, a strategy, strategic plan, etc., in which the general objectives of ICBP”NS”, the priorities and the activities to be carried out in the medium and long term, as well as an annual plan of management or any other specific ICBP”NS” planning document in order to establish the specific objectives, the activities necessary to fulfill them and the necessary resources.
3. The distribution of resources requires informed decisions and analyzes regarding the best way of allocation, given the limited nature of resources.
4. Changing the objectives, resources or other elements of the substantiation process requires updating the planning document.
5. In order to achieve the objectives, the ICBP"NS" Director ensures the coordination of the decisions and actions of the departments/laboratories and organizes prior consultations both within the departments and between them.

Standard 7- Performance monitoring
1. The director of ICBP”NS” orders the performance monitoring for the objectives and/or activities of the departments/laboratories, by means of quantitative and/or qualitative indicators, including regarding economy, efficiency and effectiveness.

2. The coordinators of the departments/laboratories monitor the performances of the activities under coordination, by developing a system adapted to the size and specifics of the department/laboratory's activity. The monitoring of the performance of the carried out activities is carried out at the level of each department/laboratory in order to inform the management of ICBP"NS" regarding the achievement of the proposed objectives.
3. The coordinators of the departments/laboratories ensure that at least one performance indicator is established for the established objectives and the activities provided for in the plan and/or carried out, with the help of which achievements are monitored and reported. Based on the established indicators, the head of the department/laboratory prepares a performance monitoring report annually, which can be included in a larger report, such as an activity report or other reporting document of the public entity.
4. On the basis of the annual performance monitoring reports received from the departments/laboratories, an information regarding performance monitoring at the ICBP"NS" level is drawn up by the Director.
5. The structure and complexity of the performance monitoring system are conditioned by the size and specifics of the ICBP"NS" activity, by the modification of the objectives and/or indicators, by the employees' access to information.
6. The management of ICBP"NS" orders the periodic evaluation of performances, ascertains possible deviations from the objectives and takes the necessary preventive and corrective measures.

Standard 8- Risk management
1. The Director of ICBP"NS" organizes and implements a risk management process to facilitate the achievement of its objectives in terms of economy, efficiency and effectiveness.
2. ICBP"NS" defines its own risk management process adapted to the size, complexity and specific environment, in order to identify all possible sources of risk and to reduce or eliminate the probability and impact of risks.
3. The management of ICBP"NS" determines the vulnerabilities and threats related to the objectives and activities, which may affect their achievement.
4. The director of ICBP"NS" has the obligation to organize and implement an effective risk management process, mainly through:
a) the identification of risks in close connection with the activities within the specific objectives, the achievement of which could be affected by the materialization of the risks; the identification of threats/vulnerabilities present within the current activities of the entity that could lead to the failure to achieve the proposed objectives and to the commission of acts of corruption and fraud;
b) risk assessment, by estimating the probability of materialization, of the impact on the activities within the objectives if they materialize; ranking and prioritizing risks according to risk tolerance;
c) establishing the risk management strategy (risk response) by identifying the most appropriate ways to treat risks, including control measures; risk analysis and management according to the risk tolerance limit approved by the entity's management;
d) monitoring the implementation of control measures and reviewing them according to the effectiveness of their results;
e) periodic reporting of the risk situation is carried out whenever necessary or at least once a year, respectively if the risks persist, depending on the appearance of new risks, the effectiveness of the control measures adopted, the reassessment of existing risks, etc.

5. The coordinators of the departments/laboratories included in the first management level of the organizational structure of ICBP”NS” nominate those responsible for risks and ensure the organizational and procedural framework for the identification and assessment of risks, the establishment of the risk management strategy, the monitoring of the implementation of control measures, the review and their periodic reporting.
6. All activities and actions initiated and implemented within the risk management process are rigorously documented, and the synthesis of data, information and decisions made in this process is included in the Risk Register, a document that certifies that within the public entity there is a risk management process and that it works; The register of risks per entity includes only the significant risks.
7. Those responsible for the risks within the departments/laboratories collect the risks related to the activities, identify the risk strategy, draw up the Risk Register at the department level.
departments/laboratories from the first management level, propose control measures and monitor their implementation, after they have been previously approved by the department/laboratory coordinator.
8. Risks are updated at the level of departments/laboratories whenever this is required, but mandatory annually, by completing the changes in the Risk Register. ICBP”NS”, according to an internal procedure and the experience gained in risk management, can use a series of tools specific to the identification and tracking of risks, such as a risk alert form, a risk tracking sheet, etc., without them having a character mandatory.
9. The control measures established by the departments/laboratories are centralized at the ICBP”NS” level and are approved by the ICBP”NS” Director. Control measures are mandatory for the management of significant risks at departmental/laboratory level and are updated whenever necessary.
10. The coordinators of the departments/laboratories in the first management level report annually on the progress of the risk management process, which mainly includes the total number of risks managed at the level of the departments/laboratories, the number of treated and unresolved risks by the end of the year, the stage of implementation of the measures control and possible revisions of the risk assessment, in compliance with the risk tolerance limit approved by the ICBP”NS” management.
11. On the basis of the annual reports received from the departments/laboratories, an information regarding the implementation of the risk management process at the ICBP”NS” level is elaborated; the information is analyzed and approved in the Monitoring Commission, after which it is presented to the ICBP"NS" Director.

Standard 9-Procedures
1. The director of ICBP”NS” ensures the development of documented procedures in a unitary manner for major processes or significant activities carried out within the entity and brings them to the attention of the staff involved.
2. The management of ICBP”NS” ensures that for the processes and activities, declared procedural, there is adequate documentation and that the operations are recorded in documented procedures.
3. In order for the procedures to become effective internal control tools, they must:
– to be specified in written documents (documented procedures);
– refer to all important processes and activities;

– to ensure a correct separation of the functions of initiating, verifying, approving and approving operations;
– to be simple, complete, precise and adapted to the processes and procedural activity;
– to be constantly updated;
- to be brought to the attention of the personnel involved.
4. The documented procedures developed must be in accordance with the structure provided in annex no. 2 of Order 600/2018 and/or with a system procedure regarding the elaboration of procedures at the level of the public entity.
5. The procedures must ensure a separation of the functions of initiating, carrying out, verifying, approving and approving the operations, so that they are entrusted to different people. In this way, the risk of errors, frauds, violations of legislation, as well as the risk of not detecting problems in the flow of a process or an activity is considerably reduced.
6. Managers of public entities in which, due to the small number of employees, the possibility of applying the separation of duties and responsibilities is limited must be aware of the occurrence of the previously mentioned risks and compensate for this limitation through additional control measures implemented on the flow of processes or activities procedural.
7. In ICBP”NS”, access to resources, as well as their protection and correct use, are regulated by administrative documents, which are brought to the attention of employees. Restricting access to resources reduces the risk of their inappropriate use.
8. The management of ICBP”NS” ensures that, for all situations in which, due to special circumstances, deviations from established policies or procedures occur, appropriate documents, approved at an appropriate level, are drawn up before the operations are carried out. The circumstances and the way of managing situations of deviation from the existing policies and procedures are periodically analyzed, in order to draw some conclusions of good practice for the future, which are to be formalized.

Standard 10- Supervision
1. The management of ICBP"NS" initiates, applies and develops appropriate tools for supervision and control of the processes and activities specific to the department, in order to achieve them in conditions of economy, efficiency, effectiveness, safety and legality.
2. The management of ICBP”NS” must monitor the application of the control tools, to ensure that the procedures are respected by the employees effectively and continuously.
3. Supervisory activities involve reviews of the activity carried out by employees, testing through surveys or any other methods that confirm compliance with the procedures.
4. Coordinators of departments/laboratories check and approve the activities of employees, give the necessary instructions to ensure the minimization of errors and losses, the elimination of irregularities and fraud, compliance with the legislation and the correct understanding and application of the instructions.
5. The supervision of the activities is adequate, insofar as:
- each employee is informed of the assigned duties, responsibilities and competence limits;
- the activity of each employee is systematically evaluated;
- the results of the activity in various stages of its realization are approved.

Standard 11- Business continuity

1. The management of ICBP"NS" identifies the main threats regarding the continuity of processes and activities and ensures the appropriate measures so that its activity can continue at any time, in all circumstances and in all plans, regardless of the nature of the threat.

2. ICBP”NS” is an organization whose activity must be carried out continuously through the component departments/laboratories. The eventual interruption of its activity affects the achievement of the established objectives.

3. The coordinators of the departments/laboratories inventory the generative situations that can lead to discontinuities in activity and draw up a business continuity plan, which is based on the identification and evaluation of the causes that can affect operational continuity.

Current situations generating discontinuities: staff turnover; lack of coordination; poor management; fraud; destruction or loss of documents; difficulties and/or malfunctions in the operation of the equipment; malfunctions produced by some service providers; changes in procedures, political and/or legislative instability, etc.

4. The business continuity plan must be known, accessible and applied in practice by employees who have established tasks and responsibilities in its implementation.

5. The management of ICBP"NS" acts in order to ensure the continuity of the activity through measures to prevent the occurrence of situations of discontinuity, for example:

– documented procedures for managing situations that may affect the continuity of processes and activities;

- delegation, in case of temporary absence (leaves, departures on mission, etc.);

- hiring staff in place of those who have retired or left the public entity for other reasons;

– purchases to replace some inadequate equipment in the endowment;

- service for the maintenance of the equipped equipment.

6. The coordinators of the departments/laboratories ensure the continuous review of the business continuity plan, so that it always reflects all the changes occurring in the department/laboratory.

Standard 12- Information and communication

1. In the ICBP”NS” the types of information, their content, quality, frequency, sources, recipients must be established and an efficient internal and external communication system is developed, so that management and employees can effectively and efficiently perform their tasks , and that the information reaches the users complete and on time.

2. The quality of information and effective communication support the entity's management and employees in the performance of tasks, responsibilities and in achieving objectives, including the goal of internal managerial control.

3. The information must be correct, credible, clear, complete, timely, useful, easy to understand and receive.

4. Information must benefit from a rapid circulation, in all directions, including inside and outside, require reduced expenses, by avoiding parallelism, that is, the simultaneous circulation of the same information on different channels or several times on the same channel.

5. The management of ICBP”NS” establishes communication flows and channels to ensure the effective transmission of data, information and decisions necessary to carry out ICBP”NS” processes.

6. The communication system must be flexible and fast, both within the ICBP”NS” and between it and the external environment, and serve the purposes of the users.
7. Communication with external parties must be carried out through established and approved communication channels, respecting the limits of responsibility and delegation of authority, established by the Director.
8. The management of ICBP”NS” systematically and periodically reevaluates information requirements and establishes the nature, size and sources of information and data that correspond to satisfying the entity's information needs.
9. IT systems support adequate data management, including database administration and data quality assurance. Data management systems and operating procedures are in accordance with the entity's IT policy, mandatory security measures and personal data protection rules.

Standard 13- Document management
1. The director of ICBP”NS” organizes and manages the process of creation, review, organization, storage, use, identification and archiving of internal and external documents of ICBP”NS”, providing control over their complete life cycle and accessibility the entity's management and employees, as well as authorized third parties.
2. In the ICBP”NS” clear rules are defined and procedures are established regarding the registration, dispatch, drafting, classification, filing, protection and preservation of documents.
3. The director of ICBP”NS” organizes and monitors the process of receiving, registering and sending documents, and at the level of each department/laboratory, a record of received and sent documents is mandatorily kept.
4.In ICBP”NS” security measures are implemented to protect documents against destruction, theft, loss, fire, etc., as well as measures to comply with regulations regarding the protection of personal data.
5. The leadership of ICBP"NS" ensures the necessary conditions for employees to know and respect the legal regulations regarding access to classified documents and how to manage them.
6. In the ICBP”NS” a document storage/archiving system is created, according to a procedure, in order to ensure their preservation in good conditions and for them to be accessible to the personnel competent to use them.

Standard 14- Accounting and financial reporting
1. The director of ICBP”NS” ensures the smooth running of the processes and the exercise of the appropriate forms of internal control, which guarantee that the data and related information used for the preparation of the annual accounting statements and financial reports are correct, complete and provided on time.
2. The director of ICBP”NS” is responsible for organizing and keeping up to date the accounting and for the timely presentation of the financial statements on the state of the patrimony under his administration, as well as the budget execution, in order to ensure the accuracy of all the accounting information under his control .
3. The coordinator of the financial-accounting department ensures the quality of the accounting information and data used to prepare the accounting statements, which truly reflect the assets and liabilities of ICBP”NS”.

4. The annual financial statements are accompanied by annual performance reports in which the objectives, expected and achieved results, indicators and associated costs are presented for each program.
5. In the ICBP"NS" properly documented accounting procedures and controls are developed aimed at the correct application of the normative acts in the financial-accounting field and internal control.

Standard 15- Evaluation of the internal managerial control system
1. The director of ICBP"NS" assigns responsibilities for evaluating internal managerial control to the Coordinators of departments/laboratories, developing policies, plans and programs for this purpose. The director of ICBP"NS" orders and monitors the evaluation of the internal managerial control through the departments/laboratories, in accordance with annexes no. 3 and 4 of Order 600/2018.
2. The director of ICBP"NS" prepares, annually, by assuming managerial responsibility, a report on his own internal managerial control system.
3. The director of ICBP"NS" ensures the continuous verification and assessment of the operation of the managerial internal control system and its components, in order to timely identify the weak points, respectively the deficiencies of the internal control and to take corrective and/or elimination measures in their useful time.
3. The management of ICBP"NS" performs, at least once a year, a check and self-evaluation of its own managerial internal control system, in order to establish its degree of compliance with the managerial internal control standards.
4. The coordinators of the departments/laboratories within ICBP"NS" take appropriate and prompt measures to remedy the weak points, respectively the deficiencies identified in the self-assessment process of the internal managerial control system; these measures are transposed annually into a program for the development of the internal managerial control system.
5. The leader of the ICBP"NS" annually prepares a report on the managerial internal control system, as a basis for an action plan that contains the identified vulnerable areas, the control tools that need to be implemented, measures and directions for action to increase the capacity of internal control managerial in achieving the entity's objectives.

CHAPTER IV
Final provisions

Art. 23 All organizational structures and salaried staff of ICBP"NS" have the obligation:

- to carry out on time and at the highest quality level the tasks set by the management of ICBP"NS";

- to respect the application of laws and solicitude towards the institutions with which they collaborate.

Article 24

(1) The duties established by the present Organizational and Operating Regulations of the ICBP"NS" are detailed for each position in the organizational structure through the "Job Description".
(2) The job description defines and delimits, mainly, elements regarding the contribution to the achievement of the goals, functions, attributions and objectives of the institution, the content and expected results of the work that will be performed, the limits of authority, the requirements and conditions that must be fulfilled a person to fill that position.
(3) The job descriptions are changed whenever the duties of the positions change.

Art. 25 The leaders of all organizational structures are obliged to ensure the knowledge and compliance of this regulation by all subordinate personnel.

These Regulations have been updated in relation to:

-Government Ordinance no. 119/1999 on internal/managerial control and preventive financial control, republished, with subsequent amendments and additions
-Government emergency ordinance no. 86/2014 regarding the establishment of reorganization measures at the level of the central public administration and for the amendment and completion of some normative acts, approved with amendments and additions by Law no. 174/2015, with subsequent amendments
-Government Decision no. 21/2017 on the organization, functioning and duties of the General Secretariat of the Government, with subsequent amendments and additions
- Order no. 600/2018 regarding the approval of the Internal Managerial Control Code of public entities with Annexes that are an integral part of this Order

Date of approval by the Scientific Council 31.10.2023

DIRECTOR,

SCIENTIFIC SECRETARY,

Acad. Maya Simionescu

Dr. Felicia Antohe

Institute of Cellular Biology and Pathology
"Nicolae Simionescu"

APPROVED

THE PRESIDENT OF THE BIOLOGICAL SCIENCES SECTION

Acad. Maya SIMIONESCU

INTERNAL REGULATIONS
-
"NICOLAE SIMIONESCU"
INSTITUTE OF CELLULAR BIOLOGY AND PATHOLOGY
OF THE ROMANIAN ACADEMY

INTERNAL REGULATIONS

On the 15th of April , 1978, according to Decree no. 152, the Institute of Cellular Biology and Pathology was established; from its establishment until 1990, the Institute was subordinated to the Ministry of Education and Training, after which it entered the structure of the Academy

The official name of the Institute is: "Nicolae Simionescu" Institute of Cellular Biology and Pathology.

The institute has the following objectives:

a. basic biomedical research and the transfer of results to the clinic.

b. ensuring the specialization and improvement of personnel in the field of cell biology and pathology, through post-university courses, specialization internships, doctorates and other forms;

c. supporting the educational process in the subjects of biology and cell pathology in which students of the faculties of biology, medicine, pharmacy, chemistry, physics etc.

d. promoting modern cellular biology and pathology in Romania;

e. the amplification of international scientific exchanges;

As part of its activity, the Institute of Cell Biology and Pathology "Nicolae Simionescu" collaborates with research institutes, higher education institutions and other units interested in scientific research and the application of results in the field of cell biology and pathology.

Also, the Institute collaborates, on the basis of conventions and agreements, with specialized Institutes from abroad, with international profile bodies, as well as with prestigious scientific personalities in the field of biology and cellular pathology.

The management of the Institute elaborated the present regulation approved by the Scientific Council of the Institute.

CHAPTER I

GENERAL DISPOSITIONS

Art.1 (1) The Internal Regulation of the Institute is drawn up in accordance with the Romanian Constitution; Labor Code; Finance Law no. 500/2002, Law 153/2017 Framework on the remuneration of personnel paid from public funds; Law on the unitary pension system no. 263/2010 with subsequent additions and amendments, HG no. no. 250/1992- regarding vacation leave and other leaves of employees from the public administration, from the autonomous regions with special specificity and from the budget units, with subsequent amendments and additions, Order 600/2018 regarding the approval of the Code of Internal Managerial Control of Public Entities, Order 974 /2020 regarding the establishment of the criteria for evaluating individual professional performance for contractual staff and the evaluation form for executive and management staff, OMFP 1917/2005-Order for the approval of the Methodological Norms regarding the organization and management of the accounting of public institutions and its application instructions , with subsequent amendments and additions, Law 752/2001-concerning the organization and operation of the Romanian Academy, with subsequent amendments and updates and with the Statute of the Romanian Academy. The internal regulation is intended to ensure the general framework of the Institute's activity and the necessary conditions for a good development of the research activity.

(2) The provisions of this Internal Regulation apply to all employees of the Institute, regardless of function, duties, place of work or duration of the contract.

(3) It also applies to those who are seconded within the Institute, to those who are pursuing a specialization or doctorate, to those who carry out collaborations in the field of scientific research, as well as to students and master's students who carry out internships or complete graduation theses in the Institute .

Art. 2. - These Internal Regulations specify the organization of research work, the rules regarding protection, hygiene and safety at work, the rights and obligations of the Institute and the employees, the procedure for resolving individual requests or complaints of employees, the rules regarding work discipline in the unit, disciplinary violations and applicable sanctions and the methods of application of specific legal or contractual provisions.

Art. 3. - (1) Labor relations are based on the principle of consensuality and good faith.

The rights and obligations regarding the labor relations between employer and employee are established according to the law and individual labor contracts.

Employees cannot waive their rights recognized by law.

Any transaction aimed at waiving the rights recognized by law to employees or limiting these rights is null and void.

Art. 4. For the smooth development of labor relations, the Institute and the employees will inform and consult each other, in accordance with the law.

Art. 5. - (1) Knowledge of and compliance with the Internal Regulation is mandatory for all categories of personnel within the Institute.

(2) Employees with the duties of heads of departments/departments will inform each employee of the content of this Internal Regulation and will make it available to them, upon request, for documentation and consultation.

(3) Any interested employee may notify the Institute regarding the provisions of the Internal Regulations, to the extent that he proves the violation of his right.

Art.6 (1) The "Nicolae Simionescu" Institute of Cellular Biology and Pathology is managed by the director together with the scientific council.

(2) The appointment of the director is made by the President of the Romanian Academy by decision for a period of four years, after the validation by the Presidium of the Romanian Academy of the results of the competition organized according to

the "Regulations for occupying management positions in the research units of the Romanian Academy" ;

(3) The appointment of the deputy director and the scientific secretary is made by decision of the head of the institute, for a period of four years, following the result of the competition organized according to the "Regulations for occupying management positions in the research units of the Romanian Academy"

(4) The scientific council consists of the president, the scientific secretary and a number of members. The director is the president of the Scientific Council. The members of the Romanian Academy who work in the Institute, the deputy director, the scientific secretary and the persons with the attributions of head of the research departments are members of the Scientific Council by right.

CHAPTER II

THE RIGHTS AND OBLIGATIONS OF THE INSTITUTE AND THE EMPLOYEES

1. THE RIGHTS OF THE MANAGEMENT OF THE INSTITUTE

Art. 7. Management The Institute has, mainly, the following rights:

• to establish the organization and functioning of the activities carried out within the Institute;

• to establish the appropriate duties for each employee, according to the law;

• to give binding provisions for the employee, subject to their legality;

• to exercise control over the way of performing work tasks;

• to ascertain the commission of disciplinary violations and to apply the appropriate sanctions, according to the law and the internal regulation.

2. OBLIGATIONS OF THE MANAGEMENT OF THE INSTITUTE

2.1 General obligations:

Art.8 The director has the following attributions:

- to represent the institute in its relations with other institutions in the country and abroad;

- is a tertiary credit orderer, according to the law;

- to elaborate in collaboration with the Deputy Director, the Scientific Secretary and heads of scientific departments the scientific research plan of the Institute and submit it to the discussion of the Scientific Council and the approval of the Biological Sciences Section of the Romanian Academy;

- to organize and control the activity of the Institute to ensure the optimal realization of the research plan;

- to follow the publication and exploitation of the results of scientific research.

- performs the duties that fall to him, according to the laws and the Statute of the Romanian Academy.

Art. 9 The management of the institute (Chap. I, art. 6.1) has the following obligations:

a. to ensure the favorable framework for the development of the research plan, to follow the publication and valorization of the scientific research results, to verify the correctness of the results and to take severe measures against those who report erroneous results in bad faith;

b. to ensure the rational use of the premises, equipment, materials, energy resources;

c. to take all the necessary measures for the good organization and development of the activity in safe conditions, for the permanent supervision of the devices and installations, of all the norms of exploitation, maintenance, repairs, maintaining order and discipline, organizing the systematic control of the duties of the Employees and drawing to the responsibility of those who violate service obligations;

d. to provide employees with the appropriate technical equipment available to the Institute, materials, documentation and protective and work equipment, to take measures to ensure their proper condition in order to make full use of the research capacity and full and efficient use of time For work;

e. to establish regulations compatible with international provisions and the code of ethics regarding the breeding, accommodation and use of experimental animals;

f. to take measures to improve the working conditions, ensure the conditions of labor protection and compliance with the hygienic-sanitary norms according to the legislation in force;

g. to ensure the conditions for the improvement and specialization of the staff in order to increase the value of the scientific and, in general, professional activity;

h. to ensure the achievement of the objectives of the Institute's activity, so that the staff can benefit from the rights deriving from the quality of employee, provided in the Labor Code and in other normative acts;

i. to take measures for the issuance of access cards (in the institute)/Employees' identification cards.

j. to establish individual performance objectives, as well as the evaluation criteria for their achievement;

k. to ensure the application of the legal provisions in force regarding health and safety at work, including the determination of possible risks that would endanger the running of activities and failure to achieve the intended objectives.

Art 10. to ensure free access to information of public interest according to the laws in force.

Art. 11. to protect professional secrecy until the results are published in specialized magazines.

3. THE RIGHTS OF THE EMPLOYEES OF THE INSTITUTE

Art.12 The staff of the Institute has the following rights:

a. to ensure stability in work, the service or work relationship not being able to terminate or be modified except in the cases provided for by law;

b. to benefit from appropriate working conditions, labor protection measures, social insurance allowance in case of temporary loss of working capacity, pension and other social insurance rights provided for by law;

c. to receive for the submitted activity the salary rights established according to the law, in relation to the professional training, the submitted activity and the performance of the service obligations;

d. to ensure weekly rest and annual paid vacation leave, under the conditions of the law;

e. to benefit from paid or unpaid study leave, under the conditions of the law;

f. to receive support and facilities for improving professional training;

g. to benefit from equal opportunities and treatment according to the law;

h. to cumulate within the ICBP-NS to the basic position and other norms remunerated from funding sources, other than those from the State Budget, under the conditions provided by the legislation in force;

4. OBLIGATIONS OF THE EMPLOYEES OF THE INSTITUTE

Art.13 The employees of the Institute are responsible for the correctness of the results of the scientific research undertaken and for managing the entrusted heritage. Each Employee is responsible for the fulfillment of his own duties and for the smooth running of the general activity of the Institute.

Art.14 The persons employed in the Institute have the following general duties:

a. to respect the work schedule and to use the working time fully and efficiently to fulfill the service obligations;

b. to carry out activities according to both the specialized training and the needs of the Institute; in special situations, determined by the need to ensure the good functioning of the Institute, everyone has the obligation to participate - independently of the function or position they occupy - in the execution of any works and in taking all the measures required by the needs of the Institute;

c. to comply with the rules and instructions regarding the performance of the activity provided for in the Internal Regulation and other internal regulations;

d. to know the constructive and functional peculiarities of the devices, machines and installations with which they work, to apply the norms of their operation and maintenance;

e. to efficiently use reagents, equipment, energy resources and to take the necessary measures to avoid waste and negligence in the preservation and administration of entrusted goods;

f. to comply with the norms of labor protection, use of protective and work equipment, fire prevention or other situations that could endanger the building, the Institute's facilities or the life, bodily integrity or health of some people;

g. to notify the hierarchical boss as soon as he becomes aware of the existence of irregularities, deviations, difficulties or shortages at the workplace, proposing measures to improve the activity, in relation to the possibilities of the Institute;

h. not to leave devices, machines and installations in operation without supervision during the work schedule or outside of it;

i. not to leave the workplace until the arrival of the shift, where there is uninterrupted work; in case of non-presentation of the exchange, to notify the hierarchical boss in order to take the necessary measures;

j. to show up to work in full working capacity, in order to properly perform their duties;

k. to take urgent measures to liquidate damages and the consequences of accidents, to be at the disposal of the Institute or to report to work as soon as possible in case of damages or other needs;

l. to respect the rules of access to the Institute and not to receive people from outside the Institute except in accordance with the rules established in the Internal Regulations;

m. to signal to the person with the duties of a duty officer the devices that operate after the program hours and the parameters of normal operation;

n. to maintain order and cleanliness at the workplace;

o. to respect the confidentiality of documents or information that are not published; research ideas and themes that present elements of novelty or priorities are considered confidential documents;

p. to have a civilized behavior in work relations;

r. to notify the superior in the shortest possible time, but no later than 24 hours, if he is absent from work for valid reasons - accident, illness, etc.

Art.15 The persons with the attributions of department heads and the persons with the attributions of heads of departments/laboratories are responsible for achieving the necessary conditions for the complete safe operation of research installations, machines and devices, for the prevention of accidents or fires, for equipping the places of working with the necessary technical operating instructions, performing technical inspections on time, taking all measures to avoid any accidents or accidental interruptions.

Art. 16 In addition to the obligations stipulated in Art. 13 and 14, the research staff is required to meet the following requirements:

b. to contribute to the expansion and diversification of scientific research in the field of cellular and molecular biology and pathology;

c. to actively participate in scientific debates, in the confrontation of ideas in the specialized scientific field and to contribute, in this way, to defining the directions of research progress, to establishing the means for improving the research process and the valorization of scientific results through publications ;

d. to participate in the training of young people for scientific research by passing on their own experience and knowledge;

e. to maintain absolute discretion over confidential data and scientific results not yet published;. not to engage, in any form, to carry out works or to provide data to natural or legal persons, foreign to the Institute, except with the approval of the Institute's management;

f. have the obligation to submit activity reports requested by the Institute's management; any information on these data, requested from outside the Institute, will be provided only with the approval of the management;

g. the periodic capitalization through publications, communications or other forms of the scientific results obtained in the Institute will be done only with the consent of the Institute's management;

h. upon prolonged temporary leave or permanent leave of the Institute (extended sick leave, maternity leave, leave without pay, transfer, resignation), the employees

engaged in the scientific research activity will hand over to the Institute management all the materials containing information on the scientific research carried out in Institute published or unpublished (workbooks, iconography, preparations, etc.), as well as the materials and reagents held for these researches.

Art.17 It is prohibited:

a. presence in the Institute of persons under the influence of alcoholic beverages; those in this situation will be evicted from the Institution, with the loss of salary rights for the respective day; in case of repetition of these circumstances, severe disciplinary measures will be taken, according to the law; the production of damages to the Institute by Employees under the influence of alcohol determines the termination of the employment contract and the recovery of the damage.

b. the unofficial introduction into the Institute of materials that could cause contamination, poisoning, fires or explosions;

c. smoking in the institute is only allowed in the places designated for this purpose;

d. practicing other activities that are not intended or subordinated to the research process without the approval of the institute management;

e. leaving the workplace unjustified or using working time for purposes other than those that are in the interest of the Institute;

f. executing works of personal interest within the premises of the Institute during work, as well as preventing others from fulfilling their work obligations;

g. carrying out any activities that could endanger the security of the Institute, of one's own person or of others;

h. committing immoral, violent acts or ill-treating people or animals, uttering insults or slander or damaging property;

i. removing from the Institute substances, materials, instruments or any other assets belonging to the Institute, without legal supporting documents, countersigned by the management;

j. leaving the Institute during program hours without a permit, work delegation or other supporting documents;

k. leaving the Institute through a place other than the one established for staff access.

CHAPTER III

GENERAL RULES OF PROFESSIONAL CONDUCT OF THE EMPLOYEES OF THE INSTITUTE

Art.18 In the exercise of their duties, the Institute's employees have the obligation to behave professionally and in accordance with the Institution's internal norms.

Art.19 The employees of the Institute have the obligation to, through their behavior, respect the Constitution, the laws of the country and to act for the implementation of the legal provisions, in accordance with their attributions, respecting professional ethics.

Art. 20 (1) The employees of the Institute have the obligation to loyally defend its prestige, as well as to refrain from any act or fact that may harm the image or legal interests of this institution.

(2) Employees of the Institute are prohibited from the following:

a. to publicly express assessments inconsistent with reality regarding the institution's activity, its policies and strategies or its development projects;

b. to make unauthorized judgments in connection with the disputes that are being resolved and in which the Institute is a party;

c. to disclose information that is not public, under conditions other than those provided by law, if they are not authorized to do so;

d. to disclose the information to which they have access in the performance of their duties, if this disclosure is of a nature to attract undue advantages or to prejudice the Institute's image or rights;

Art.21 (1) In the interpersonal relations of the employees of the Institute, as well as with other natural or legal persons, the employees are obliged to behave based on respect, good faith, correctness and kindness.

(2) Employees have the obligation not to harm the honor, reputation and dignity of the people within the Institute, as well as the people they come into contact with in the exercise of their duties, by:

a. the use of offensive expressions;

b. revealing some aspects of private life;

c. formulating slanderous notifications or complaints.

(3) The employees have the obligation to use the working time, as well as the goods belonging to the Institute, exclusively for carrying out the activities related to the established service attributions.

CHAPTER IV

Employment criteria

Art.22 Employment within the ICBP is done under the conditions of the law, based on the decision of the director of the Institute.

Art.23 (1) Hiring is done through competition or, as the case may be, examination, for vacant positions.

(2) Existing vacancies in the staff list will be put out to competition.

(3) To fill a vacant or temporarily vacant contractual position, the candidate must meet the following general conditions according to art.3 of the Regulation - framework approved by Government Decision no.286 of March 23, 2011, art.15 of H.G.1336/2022 regarding the Regulation -framework regarding the organization and career development of contractual staff in the budgetary sector paid from public funds:

a) has the Romanian citizenship or of another member state of the European Union, of a state party to the Agreement on the European Economic Area (EEA) or the citizenship of the Swiss Confederation;

b) knows the Romanian language, written and spoken;

c) has the capacity to work in accordance with the provisions of Law 53/2003-Labor Code, republished, with subsequent amendments and additions;

c) has the minimum age regulated by the legal provisions;

d) has full exercise capacity;

d) has a state of health corresponding to the position for which he is applying, attested on the basis of the medical certificate issued by the family doctor or by the competent health units;

e) fulfills the conditions of studies and, as the case may be, seniority in the specialty or other specific conditions according to the requirements of the position put up for competition;

f) has not been definitively convicted for committing a crime against national security against humanity, crimes of corruption or service crimes, crimes of forgery or against the administration of justice, crimes committed with intent that would make a candidate for a position incompatible with the exercise of the contractual function for which he is applying, except for the situation in which rehabilitation has taken place.

g) he does not serve a complementary punishment by which he was prohibited from exercising the right to occupy the position, to exercise the profession or trade or to carry out the activity that was used to commit the crime, or the safety measure of the prohibition of occupation was not taken in relation to this a function or the exercise of a profession.

(4) The competition announcement will be published in a central newspaper, on the internet page or by display at the Institute's headquarters, at least 30 calendar days before the date of the competition for research positions and on the posturi.gov.ro portal through to the e-mail address posturi@gov.ro and on the website of the Institute at least 15 days before the date of the competition or exam for filling a vacant position, respectively at least 10 working days for filling a temporary vacant position for staff contractual.

(5) The composition of the competition or examination commission for employment or promotions is determined by the decision of the director of the Institute. The commission is led by a president, and the secretary of the examination commission is responsible for the good organization and development of the competition and is not a member of the commission.

(6) The competition will consist of a written test and an oral test or interview, as the case may be, for contractual staff, for research staff, the competitions are organized

according to Law 319/2003 on the status of research and development staff and according to GD no. 1336/ 2022 for contract staff

Art.24 (1) Hiring for the occupation of research positions (a minimum average of 8 is required to pass the exam), execution or management is done after the prior verification of the professional skills of the applicant, in order to assess the ability to occupy the respective position, based on evaluation criteria with the establishment of a trial period.

(2) The trial period is:

a) max 90 calendar days for research and execution functions,

b) max 120 calendar days for management positions and constitutes length of service.

(3) Advancement in professional grade for staff employed in research functions is done only on a vacant position, and for contractual staff employed in execution functions, it is done upon request, by changing the position occupied by the employee and in relation to:

a) minimum experience of 3 years in the previous professional degree,

b) the results obtained in the activity, according to the last evaluation,

c) passing a written and oral exam with a minimum average of 8.

(4) The individual employment contract concluded between the employer and the employee must include the elements provided in the framework model, approved by Order of the Ministry of Labor and Social Solidarity no. 2171/2022, with subsequent amendments and additions. After the conclusion of the individual employment contract the employee takes note of the provisions of this regulation.

The elements of the individual employment contract can be changed under the conditions of the law the legislation in force.

The job description is an annex to the individual employment contract and is an integral part of it.

Employees of the Institute who are on leave granted according to the legal provisions or whose individual employment contracts are suspended under the law,

are granted on the date of resumption of activity, the basic salary related to the professional grade or step in which they were assigned before the suspension.

CHAPTER V

ORGANIZATION OF WORKING TIME IN THE INSTITUTE

Art.25 The usual duration of working time in the Institute is on average 40 hours per week, 8 hours per day, five days per week. Within a week, the daily work schedule is differentiated by fields of activity.

Art.26 The weekly rest is ensured for all staff on Saturdays and Sundays and on legal holidays, with the exception of persons with the duties of duty officers and guards - porters, to whom the weekly rest can be granted on other days, according to the shift schedule.

Art.27 The modification of the work schedule, as well as the organization of the shift schedule in certain compartments, are made by the Institute's management in relation to the research needs, in compliance with the legal provisions.

Art.28 The persons with the duties of heads of departments/laboratories and of the other work collectives have the obligation to organize the activity in the compartments they coordinate in such a way that the job duties, specified in the job descriptions they draw up for subordinate personnel, are carried out in most cases during working hours. Together with the economic-administrative sector, they ensure the correct recording of the working time performed. The job descriptions will be recorded by the Institute's management.

Art. 29 (1) The performance of work beyond the normal duration is allowed in special situations (preventing or removing the effects of calamities or other cases of force majeure, repairing machinery or installations, etc.), as well as based on the provisions and approval of the Institute's management.

(2) In order to ensure the smooth development of the Institute's activity, work beyond the normal duration can also be performed in situations required by the specifics of the research activity. In this situation can be the personnel who work on rest days for the continuation of some experiments, for the supervision of laboratory animals, for

the finalization of some works in order to fit into the established terms and to ensure the good functioning of the equipment and installations.

(3) The activities beyond the normal working hours will be recorded in the "Register of evidence of presence in the Institute outside the program hours" and approved by the hierarchical superior and the management of the Institute.

(4) The hours worked overtime without these approvals recorded in the Register of attendance at the Institute outside the hours of the program are not taken into account for any requests for compensation for the time worked overtime.

Art.30 The time in which a person performs work beyond the normal working time is compensated according to the laws in force in the following 60 days; the compensation of the hours provided by the employees with duties of officers on the Institute can be done in the next 60 days.

Art.31 (1) Pregnant women and those who are breastfeeding will not be used in medically contraindicated activities and will not work overtime. The time for the care and feeding of the child is granted according to the legislation in force.

(2) Also, people who work with a reduced schedule, given to restore their health, will not work overtime.

Art.32 (1) The service at the Institute outside the program hours is provided by the employees with duties of service officers hired for this purpose and among the executive staff, according to the monthly schedules approved by the Institute's management. Failure to show up for guard duty is sanctioned by the withdrawal of a step or gradation for a period of 3 months, after a prior disciplinary investigation

Art.33 The security of the Institute is organized by the administrative economic department and is carried out by the security personnel employed for this purpose. The security plan of the Institute is presented in Annex 1.

Art. 34 (1) Evidence of the presence of staff at the work schedule is kept through attendance conditions. Each employed person has the obligation to personally sign the attendance certificate, daily, upon entering and leaving work. Those who have not signed the condition of presence, do not have a leave ticket in the interest of work or personal, delegation or medical certificate, are considered absent without reason on the respective day.

(2) The attendance conditions will be made available to the staff in the morning. At the beginning of the program of each category of personnel, the conditions will be withdrawn by the responsible employee designated from the administrative economic compartment; the person in charge will record attendance, delays, motivated and unmotivated absences. At the end of the program, the present conditions will be made available to the staff according to the program of each category, after which they will be kept by the employees with duties of service officers.

(3) Departures during the program, in the interest of work or personal, are made only on the basis of permission tickets (delegations) that were previously issued by the heads of departments / laboratories and approved by the Institute's management.

Art.35 (1) Leave in personal interest can only be taken with the prior approval of the Institute's management, without which leaving the Institute in personal interest is considered an unmotivated absence.

(2) The time not worked as a result of requests in personal interest, up to 4 hours, is calculated by equating hour to hour. A personal leave of over 4 hours per day is equivalent to one working day.

(3) Time not worked as a result of delays is compensated in the following 7 days.

(4) Non-working time can be:

- compensated by overtime;

- compensated by guards, if the needs of the Institute require it;

- compensated by vacation days.

(5) Delays and excessive personal absences are considered violations of work discipline and may be sanctioned according to the Labor Code.

Art. 36 Access to the Institute is allowed on the basis of the access card/service ID issued every six months, the provisional permit mentioned in art. 38 para. 2 and entrance tickets.

Art.37 In the compartments where they carry out their activity, the employees of the Institute will wear gowns, protective or work equipment. The card/identity card cannot be alienated.

Art. 38 (1) The person who loses his card/identity card, or the equipment with the Institute's insignia, is obliged to immediately notify the hierarchical superior and the economic-administrative department.

(2) Persons who have lost their service cards/identification cards will be issued temporary access permits until new identification cards are issued according to the legal provisions.

(3) The record of lost or stolen cards will be carried out by the economic-administrative department, which has the obligation to communicate this to the security personnel in order to prevent their use by other persons.

Art.39 It is forbidden for people outside the Institute to photograph/record in the Institute without the approval of the director of the Institute.

Art.40 Short-term access to the Institute by a person from outside is allowed on the basis of the identity card or identity card, with the telephone announcement of the requested Employee, who will pick it up from the entrance hall and will be responsible for the behavior of that person in the Institute.

Art.41 After finishing or outside the program hours, the presence of the staff in the Institute is allowed with the consent of the higher hierarchical boss. Employees with the duties of duty officers have the obligation to keep records of the persons remaining in the Institute outside of the program hours.

Art. 42 (1) In the case of employment with an individual work contract at home, in special situations, both the employees and the management of the Institute have the same rights and obligations, stipulated in the individual work contract and in these Internal Regulations.

(2) Home-based employees perform their specific tasks, establishing their schedule in agreement with the Institute's management and respecting the rules specific to scientific research activity.

(3) In the content of the individual work at home contract, it is mandatory to expressly mention the fact that the employee works at home, the schedule in which the employer has the right to control the employee's activity and the specific way of carrying out the control, the way of verifying the fulfillment of tasks and responsibilities provided in the job description according to the Labor Code.

Art. 43 (1) Employees have the right - under the law - to a paid holiday every calendar year.

(2) Rest leave is granted to employees in accordance with the legal provisions and is granted proportionally to the activity performed in a calendar year.

For employees employed during the year, the duration of the vacation leave is determined proportionally to the period worked from employment to the end of the respective calendar year.

(3) The rest leave is carried out every year.

If the employee, for justified reasons, cannot take, in whole or in part, the annual leave to which he was entitled in the respective calendar year, with the consent of the person in question, the employer is obliged to grant the unused leave in a period of 18 months starting with the year following the one in which the right to annual leave was born.

Compensation for unused vacation is allowed only in case of termination of the individual employment contract.

(4) The vacation is carried out on the basis of an individual appointment established by the employer with the consultation of the employee. Programming is done until the end of the calendar year for the following year.

(5) Individual programming can determine the date of the leave or, as the case may be, the period during which the employee has the right to take the leave, a period that cannot exceed 3 months.

(6) Within the leave periods established according to paragraph (4), the employee can request the leave at least 30 days prior to its taking.

(7) In case the vacations are scheduled in fractions, the employer is obliged to establish the schedule in such a way that each employee takes at least 10 working days of uninterrupted leave in a calendar year.

Proposals for the nominal scheduling of holidays are made by department heads after prior discussion with subordinate staff and are approved by the Institute's management. The employees of the Institute are obliged to take their vacations on the planned date. In unforeseen cases, rescheduling is allowed.

(8) Employees may be recalled from leave, by written order of the Institute's management, for unforeseen service needs, which require the presence of those in question at the Institute.

(9) The records of vacations are kept by activity departments and by the human resources department.

Art. 44 (1) According to the regulations in force, employed persons may request, after the exhaustion of the legal vacation leave, unpaid leave for professionally justified reasons: appearing for exams, supporting the doctoral thesis, training doctoral students with scholarships, specializations abroad, etc. .

(2) The length of service during the leave without pay will be established in accordance with the provisions of the law.

Art.45 (1) Employed persons have the right to allowances in case of temporary loss of work capacity, according to the legislation in force.

(2) Persons who have lost their ability to work are obliged to notify the Institute without delay about the state of their health and to present the supporting documents in this sense.

(3) For serious cases, family members have this duty, so that the person in question can benefit from the rights due to him.

CHAPTER VI

LABOR HYGIENE AND SAFETY RULES

Art.46 Each employee has the obligation to ensure the application of measures related to his safety and health at work, as well as that of other employees, according to the legislation in force.

Art. 47 (1) In case of special events, accidents at the workplace, each employee will urgently inform the management of the Institute.

(2) All accidents occurring during service, especially those with serious consequences, will be immediately brought to the attention of management.

(3) The same rules will be respected in the case of accidents occurring on the home-work route and vice versa.

Art.48 In order to ensure safety at the workplace, employees have the following obligations:

a. employees are responsible for complying with the rules of hygiene and work safety techniques;

b. it is prohibited to keep, distribute or sell substances or medicines whose effect can produce behavioral disturbances, within the Institution's premises;

c. it is prohibited to introduce, distribute or facilitate the introduction of alcoholic beverages in the premises of the Institution, with the exception of festive days of the Institute.

CHAPTER VII

RULES REGARDING COMPLIANCE WITH THE PRINCIPLE OF NON-DISCRIMINATION AND AL

REMOVAL OF ANY FORM OF VIOLATION OF DIGNITY

Art. 49 (1) The principle of equal treatment for all employees operates within the labor relations.

(2) Any discrimination against an employee is prohibited, according to the legislation in force.

Art. 50. (1) Every employee benefits from working conditions appropriate to the activity carried out, social protection, security and health at work, as well as respect for his dignity and conscience, without any discrimination.

(2) The right to equal pay for equal work, the right to the protection of personal data, as well as the right to protection against illegal dismissals are recognized to all employees who perform a job.

Art. 51. Sexual harassment of a person by another person at the workplace is considered discrimination based on gender and is prohibited and may be sanctioned according to the legislation in force.

Art. 52. (1) Employees have the obligation to make efforts to promote a normal work climate in the unit, respecting the provisions of the law, employment contracts, internal regulations, as well as the rights and interests of all employees.

(2) In order to create and maintain a working environment that encourages respect for the dignity of each person, procedures for the amicable resolution of individual employee complaints, including those regarding cases of violence or sexual harassment, can be carried out, in addition to those provided by law.

CHAPTER VIII

DISCIPLINARY ACTIONS

Art.53 (1) Violation of service obligations, including plagiarism, any fraud or deviation from the rules of conduct, constitutes a disciplinary offense and is sanctioned as such, regardless of the function or position held by the person who committed it.

(2) Disciplinary sanctions are applied according to Art. 248 paragraph 1 of the Labor Code and are the following:

a) the written warning;

b) demotion from the position, with the granting of the salary corresponding to the position in which the demotion was ordered, for a duration that cannot exceed 60 days;

c) reduction of the basic salary for a duration of 1-3 months by 5-10%;

d) reduction of the basic salary and/or, as the case may be, the management allowance for a period of 1-3 months by 5-10%;

e) disciplinary cancellation of the individual employment contract. Art. 54. (1) When establishing the sanction to be applied to a person for the offense committed, the causes and gravity of the act, the conditions in which it was committed, the degree of guilt of the person in question, whether or not he had deviations, as well as the consequences of the deviation on the smooth running of the Institute.

(2) Under the penalty of absolute nullity, no measure, with the exception of the one provided for in art. 248 para. (1) lit. a) The Labor Code cannot be ordered before a preliminary disciplinary investigation has been carried out. The person in question will be heard and the claims made by him in his defense will be investigated

Art.55 (1) In order to initiate disciplinary action, it is necessary that the Institute's management be notified in advance about the commission of a violation. As a rule, the reporting document is drawn up by the hierarchical boss of the one in question.

(2) The report (finding) can be drawn up in the form of a report that includes data about the name and surname of the accused: function, place of work, description of the offense, degree of guilt, discussion of defenses, disciplinary antecedents, sanction proposal.

(3) The management of the unit, receiving the referral, entrusts the performance of the preliminary investigation to a competent and neutral commission.

(4) The commission that conducts the investigation must document itself on the conditions and circumstances of the facts considered as misconduct. It must collect the evidence that can lead to the establishment of the factual situation and the guilt, the statements (explanatory notes of the people who witnessed or took direct knowledge of the commission of the offense).

(5) The commission that carries out the investigation must summon the accused, show him what the accusation consists of and listen to him in relation to the deed he is accused of.

(6) Taking into account its importance, the proof of listening to the accused is made with his written explanatory note or with the act by which the person conducting the investigation relates what the accused declared in his defense.

(7) The explanatory note is always made in writing and must be signed by the accused. If the accused refuses to give the explanatory note, a verbal process will be concluded with 2 witnesses to record the refusal to give the explanatory note. The signature of the witnesses and the one doing the research always becomes mandatory. Listening to the accused and verifying his arguments in his defense must be prior to the application of the sanction, and non-compliance with these conditions, imperatively imposed by the law, leads in certain cases to the annulment of the sanctioning decision.

Art.56 In the case of violation of the rules regarding order and discipline at the workplace, the staff of the compartment to which the guilty person belongs can discuss the committed violation, request and propose to the Institute's management in writing, the application of disciplinary sanctions.

Art.57 (1) The bodies authorized to apply disciplinary sanctions are, within the limits of their competence, the following: heads of departments, the director, the scientific council.

(2) The "warning" sanction can be applied by department heads; the other sanctions are applied by the management of the Institute.

(3) For the staff appointed by the higher hierarchical forum, the disciplinary sanction is applied by that forum.

(4) For the staff appointed with the approval of the higher hierarchical forum or the Scientific Council, the termination of the employment contract is done with the approval of these forums.

Art.58 Disciplinary violations committed by a person assigned to work during the delegation to another unit, are sanctioned by the management of the unit that delegated it.

Art.59 (1) Disciplinary termination of the employment contract cannot be done while the person in question is on leave for temporary incapacity for work, in case of pregnancy, during maternity leave, while taking care of the sick child in age up to 3 years.

(2) The decision regarding the disciplinary termination of the employment contract is communicated to the person in question within 5 days, under the signed hatred. It produces its effects from the date of communication.

Art.60 Criminal or material liability, or the application of a measure of moral influence does not exclude disciplinary liability for the committed deed, if by this work obligations were also violated.

Art.61 (1) The disciplinary sanction can be established and must be communicated in writing to the person in question within no more than 30 days from the date when the person entitled to apply it became aware of the commission of the offense, without being able to exceed 6 months from the date the offense was committed. If these terms have expired, the disciplinary sanction can no longer be applied.

(2) In the written communication that is made to the employed person, in relation to the sanction applied, the means of appeal, the deadline for filing the complaint and the competent bodies to resolve the complaint will also be provided.

(3) The disciplinary termination decision of the individual employment contract is issued in writing and, under the penalty of absolute nullity, must be motivated in fact and in law and include details regarding the term in which it can be contested and at

the court at which is contested. Art.62 (1) Against the disciplinary sanction, the sanctioned person can make a written appeal within 30 days from the notification of the sanction. The appeal is resolved within 30 days by:

a. the person occupying the hierarchical position immediately superior to the one who applied the sanction;

b. Scientific Council for sanctions applied by the director;

c. court, if the sanction consists in the disciplinary termination of the employment contract.

(2) In these cases, the pronounced decisions are final.

Art.63 The disciplinary sanction applied to a person - with the exception of the termination of the employment contract - is considered not to have been taken if the employee has not committed another offense within one year of its execution.

CHAPTER IX

RESOLVING THE PROPOSALS, COMPLAINTS AND REQUESTS OF THE EMPLOYEES IN THE INSTITUTE

Art.64 (1) The management of the Institute examines and clarifies the reported problems of personal or general interest and is responsible for solving them promptly, according to the laws.

(2) The management of the Institute is responsible for the objectivity of the research carried out, for the validity and fairness of the conclusions drawn and the legality of the established measures, for the accuracy and effectiveness of the answers given.

Art.65 Notifications and complaints directed against the activity of the Institute's management are investigated and resolved by the hierarchically superior forums.

Art.66 Examining and resolving them is mandatory within 30 days of receipt. For those that require a longer research, the term can be extended by a maximum of 30 days by the head of the Institute. Exceptionally, for those that cannot be resolved within this term, longer extensions can be approved.

Art.67 The management of the Institute will ensure the investigation and quick and thorough resolution of the problems raised by the employees, in compliance with the legal provisions.

CHAPTER X

FINAL PROVISIONS

Art.68 (1) The Internal Regulation is approved by the Scientific Council and signed by the Director of the Institute and the Scientific Secretary. After signing, the Internal Regulation will be made known to all Employees.

(2) The Internal Regulation can be amended, according to the procedure provided for its preparation, whenever the needs related to the good organization of the activity and work discipline in the Institute require changes.

Art.69 The adopted Internal Regulation is updated according to the laws and modified under the conditions stipulated by the legal provisions.

Art.70 These Internal Regulations are completed with all Operational Procedures existing on the date of its issuance or issued after approval within the ICBP.

Date of approval by the Scientific Council .....

Signing date

DIRECTOR,

SCIENTIFIC SECRETARY,

Acad. Maya Simionescu

Dr. Felicia Antohe

Două cercetătoare de la Institutul de Biologie și Patologie Celulară „Nicolae Simionescu” au câștigat Bursa L’Oréal-UNESCO 2025

Cercetătoarele Teodora Barbălată şi Mădălina Gheţu, de la Institutul de Biologie și Patologie Celulară „Nicolae Simionescu” al Academiei Române, sunt laureate ale Bursei L’Oréal-UNESCO „Pentru Femeile din Ştiinţă”, ediția 2024-2025, secțiunea „Științele Vieții”. Gala de premiere *a celei de-a XV-a ediții a acestui program de burse private, derulat în parteneriat cu Comisia Națională a României pentru UNESCO*, s-a desfășurat marți, 2 decembrie 2025, la Institutul Franței din București.

Teodora Barbălată este cercetătoare postdoctorală în biologie, în cadrul Departamentului Lipidomică, Institutul de Biologie și Patologie Celulară „Nicolae Simionescu”. Proiectul ei își propune identificarea unei metode țintite de tratament pentru boala ficatului gras non-alcoolic, o afecțiune cu incidență din ce în ce mai crescută, dar care nu beneficiază încă de un tratament specific. Proiectul este intitulat *siRNA inhibition of long non-coding RNAs and CRISPR/dCas9-induced overexpression of endogenous genes; a new therapeutic approach for treating non-alcoholic fatty liver disease*.

Mădălina Gheţu este doctorand și asistent de cercetare în cadrul Departamentului de Inginerie Celulară şi Tisulară, Institutul de Biologie și Patologie Celulară „Nicolae Simionescu”. În proiectul ei urmărește dezvoltarea unor noi strategii terapeutice utilizabile în fibroza cardiacă pentru care, actualmente, nu există tratament specific. Titlul proiectul său este *Innovative Antifibrotic Strategies: Evaluating Nanoformulated Natural Compounds in Human Cardiac Organoids*. Ea își propune să utilizeze nanoformulări în care va îngloba compuși naturali cu potențial antifibrotic și, ulterior, îi va testa pe modele de inimă în miniatură (organoizi), o alternativă la modelele experimentale animale.

De-a lungul edițiilor, Bursa L’Oréal-UNESCO „Pentru Femeile din Ştiinţă” a mai fost acordată următoarelor cercetătoare din cadrul Institutului de Biologie și Patologie Celulară „Nicolae Simionescu” al Academiei Române: acad. Maya Simionescu (2001), Elena Butoi (2011), Monica Ţucurescu (2018) și Raluca Ţuțuianu (2022). Precizăm că acad. Maya Simionescu a fost distinsă în 2001 cu premiul special *UNESCO – L’Oreal Special Honor Award for Women in Science*.

Anul acesta, L’Oréal România a acordat 10 burse, fiecare în valoare de 10.000 de euro. La această ediție aproximativ 80 de candidate au aplicat în cadrul programului, dosarele fiind evaluate de un juriu format din academicieni, profesori universitari și doctori din cele trei arii de cercetare vizate, științele vieții, științele fizice și informatică.

Programul național de burse private L’Oréal – UNESCO „Pentru Femeile din Știință” a fost lansat în România în 2009.

11 decembrie 2025

Acad. Maya Simionescu,

Doctor Honoris Causa al Universității de Medicină, Farmacie, Științe și Tehnologie

din Târgu Mureș

Academician Maya Simionescu, Președinta Secției de Științe Biologice a Academiei Române, personalitate marcantă a cercetării biologiei celulare din România și cercetător cu un bogat palmares științific internațional, a primit joi, 11 decembrie 2025, titlul Doctor Honoris Causa acordat de Universitatea de Medicină, Farmacie, Științe și Tehologie „George Emil Palade" din Târgu Mureș.

Prof. dr. Leonard Azamfirei, rectorul UMFST, a subliniat că universitatea din Târgu Mureș își datorează numele inițiativei Acad. Maya Simionescu, care a colaborat îndeaproape cu celebrul profesor George Emil Palade, laureat al Premiului Nobel: „În fiecare an, cu ocazia Zilelor Universității, acordăm titlul de Doctor Honoris Causa unei personalități care s-a remarcat într-un mod deosebit la nivel mondial, în ceea ce privește știința, cultura (...) și într-un mod obligatoriu aceste persoane trebuie să fi făcut ceva de-a lungul timpului, ceva consistent pentru Universitate.

În acest an, decizia Senatului Universității a fost ca doamna Academician Maya Simionescu să primească această distincție onorantă. Faptul că această Universitate de Medicină, Farmacie, Științe și Tehnologie poartă numele savantului de origine română, George Emil Palade, i se datorează."

Laudatio a fost rostit de prof. univ. Anca Sim, care a scos în evidență faptul că acad. Maya Simionescu „este o personalitate remarcabilă și complexă, un ilustru om de știință, adevărat simbol al datoriei împinite pe drumul desăvârșirii și al perfecțiunii (....), clasată pe primul loc în topul «Best Scientists – 200 de personalități din domeniul biologiei și biochimiei»".

În partea a doua a ceremoniei, acad. Maya Simionescu a acordat răspunsul de mulțumire, încheiat cu o caldă pledoarie pentru dezvoltarea cercetării științifice și pentru munca de echipă: „Cercetarea este una dintre aventurile cele mai frumoase ale spiritului uman – un Everest al cunoașterii, o aventură de echipă, fără limite, fără bariere; este un drum infinit, precum Coloana lui Brâncuși, un drum spre cunoaștere. Câte unul dintre noi ajunge în vârf. Vârful este simbolul recunoașterii. Dar adevărata bucurie se află în ascensiunea comună, în drumul către culmi, presărat și cu tristețea nereușitelor, dar și bucuria succesului. Cercetarea este Everestul spiritului uman, o aventură unde îmi place să cred că imposibilul nu există".

REZUMATUL TEZEI DE DOCTORAT

Scopul acestei lucrari a fost atat evidentierea plasticitatii celulelor stem mezenchimale din surse fetale cat si evaluarea potentialului terapeutic al celulelor stem fetale si implicatiile acestora in medicina regenerativa. Astfel, am dorit sa investigam capacitatea de diferentiere a celulelor mezenchimale izolate din gelatina Wharton catre celule endoteliale progenitoare si sa evaluam potentialul de regenerare tisulara cardiovasculara al acestora. In acest scop ne-am propus sa stabilim un model *in vitro* bazat pe tesut vascular fetal uman pornind de la arterele din cordonul ombilical in vederea investigarii potentialului de recelularizare al celulelor endoteliale progenitoare deiferentiate din celule stem mezenchimale fetale.

Totodata, am dorit sa investigam plasticitatea celulelor stem mezenchimale din lichidul amniotic prin analiza aprofundata a capacitatii acestora de a se diferentia in celule endoteliale progenitoare in vederea evaluarii potentialului terapeutic. In acest scop am dorit sa investigam atat imunofenotipul cat si profilul transcriptomic al celulelor mezenchimale din lichidul amniotic dar si detaliile ultrastructurale ale celulelor endoteliale diferentiate din celulele mezenchimale din lichidul amniotic.

Teza este structurata in doua parti. Prima parte, **Studiul actual al cunoasterii** este organizata in 3 capitole in care sunt descrise aspecte legate de celulele stem (Capitolul 1 din *Studiul actual al cunoasterii*), precum ierarhizarea celulelor stem si rolul lor (Capitolul 1.1 din *Studiul actual al cunoasterii)* cat si capacitatea acestora de a se diferentia (Capitolul 1.2 din *Studiul actual al cunoasterii*). Urmeaza o descriere a tipurilor de celule in functie de sursa din care sunt obtinute acestea cat si o trecere in revista metodelor de izolare (Capitolul 2 din *Studiul actual al cunoasterii*), iar in ultimul capitol este detaliata utilizare celulelor stem atat in cercetarea fundamentala si in cercetarea farmacologica cat si in medicina regenerativa (Capitolul 3 din *Studiul actual al cunoasterii*).

In cea de-a doua parte a lucrarii, **Contributia originala** studiile au fost structurate in doua capitole. In vederea evaluarii potentialului de recelularizare vasculara al celulelor stem fetale izolate din gelatina Wharton (Capitolul 1 din *Contributia originala*) am urmarit izolarea, caracterizarea si diferetierea celulelor mezenchimale din gelatina Wharton catre o linie endoteliala si stabilirea unui model *in vitro* bazat pe tesut vascular fetal uman pornind de la arterele din cordonul ombilical. Astfel am dorit sa investigam potentialul de recelularizare al celulelor endoteliale progenitoare atat la nivel histologic cat si la nivel imunofenotipic.

Rezultatele obtinute demonstreaza capacitatea celulelor stem mezenchimale din gelatina Wharton de a se diferentia catre celule endoteliale progenitoarea cu un real potential terapetutic in regenerarea vasculara. Aceste celule ar putea avea un impact major in medicina regenerativa datorita imunogenicitatii scazute si potentialului terpeutic.

In studiul privind evaluarea plasticitatii si potentialului terapeutic al celulelor din lichidul amniotic (Capitolul 2 din *Contributia originala*) am urmarit realizarea unei caracterizari complete a acestor celule, la nivel imunofenotipic, ultrastructural si molecular. In acest scop am utilizat citometria de flux pentru investigarea makerilor de suprafata, microscopia electronica si tehnica de real-time PCR (Capitolul 2.3.1 din *Contributia originala*). In acelasi timp, am dorit sa evaluam potentialul de diferentiere al celulelor din lichidul amniotic prin inducerea diferentierii catre celule endoteliale (Capitolul 2.3.2 din *Contributia originala*). Deasemenea, am urmarit stabilirea fenotipului celulelor stem CD117 pozitive din lichidul amniotic prin sortarea acestora si analiza imunofenotipica a culturilor de celule CD117 pozitive obtinute (Capitolul 2.3.3 din *Contributia originala*).

Rezultatele obtinute demonstreaza capacitatea celulelor din lichidul amniotic de a se diferentia in celule endoteliale mature prin prezenta markerilor de suprafata specifici acestor celule, dar si prin prezenta structurilor intracelulare specifice precum veziculele plasmalemale si corpusculii Weibel-Palade. Mai mult decat atat am observat diferentele imunofenotipice ale celulelor CD117 pozitive din populatia heterogena de celule din lichid in vederea stabilirii relatiilor dintre celulele CD117 pozitive si CD117 negative in cadrul populatiei heterogene.

In concluzie, in ceea ce priveste potentialul regenerativ al celulelor izolate din gelatina Wharton, rezultatele noastre au demonstrat ca arterele decelularizate din cordon ombilical uman pot fi utilizate ca matrici acelulare si reprezinta un bun model experimental *in vitro*. Am demonstrat ca EPC-urile diferentiate din MSC-uri din gelatina Wharton pot repopula tesutul vascular lezat/decelularizat evidentiat de expresia markerilor specifici fenotipului endotelial CD31+/CD34+/CD105+/CD133+ la nivelul arterelor recelularizate. Datele de histologie si citometrie de flux obtinute sugereaza ca EPC-urile diferentiate din MSC-uri de origine fetala au un intalt potential terapeutic, prin capacitatea acestora de repopulare a vaselor de sange lezate/decelularizate.

In ceea ce priveste celulele izolate din lichidul amniotic, putem concluziona ca aceste prezinta un imunofenotip specific celulelor stem mezenchimale prin exprimarea markerilor CD29, CD90 si CD73. Imunofenotipul CD29+/CD90+/CD105+/CD133+/CD146+ al acestor celule, ne sugereaza prezenta unor markeri specifici si altor tipuri de celule, precum CD105

specific celulelor endoteliale si CD133 prezent pe suprafata celulelor stem hematopoietice si a celulelor endoteliale progenitoare. In ciuda capacitatii foarte ridicate de proliferare a celulelor din lichidul amniotic, imunofenotipul acestore se modifica dupa 10 zile in cultura, devenind CD29+/CD90-/CD105-/CD133-/CD146+. La nivel molecular AFC-urile prezinta atat markeri de celule stem mezenchimale, precum ACAN, BGLAP, COL2A1 si PPARG, cat si markeri transcriptomici specifici celulelor stem embrionare cum ar fi OCT4, REX1 sau SOX2. Interesant de notat este prezenta unor markeri specifici celulelor stem hematopoietice precum CD3D, CD4, CD8A sau MME si a unor markeri specifici celulelor stem neurale cum ar fi NCAM1, SIGMAR1 si S100B. Aceste rezultate ne conduc spre ipoteza prezentei unui numar limitat de markeri specifici tuturor liniilor celulare la nivelul celulelor stem. Acest fenomen ar putea fi corelat cu potentialul de diferentiere, ca rapuns la stimuli externi prin existenta unor molecule “primer” care conduc diferentierea in functie de stimului aplicat.

Totodata, AFC-urile prezinta capacitatea de diferentierea catre linia endoteliala. Aceste se pot diferentia in celule cu imunofenotip specific celulelor endoteliale mature asa cum a fost demonstrat prin tehnica citometriei de flux, de prezenta markerilor endoteliali CD31, CD105 si CD144. Un element de noutate important il reprezinta analiza ultrastructurala a AFC-urilor diferentiate care a demonstrat prezenta structurilor intracelulare specifice celulelor endoteliale precum veziculele plasmalemale si corpusculii Weibel-Palade. Astfel, aceste celule nu au capacitatea doar de a fi ghidate catre o linie endoteliale, ci pot deveni chiar celule endoteliale mature cu structurile necesare unei posibile indepliniri a functiilor acestora, cum ar fi de exemplu veziculele plasmalemale care ar putea fi implicate in procesele de transcitoza.

Ca **perpective** de viitor dorim sa investigam capacitatea celulelor din lichidul amniotic de a repopula vase de sange lezate/decelularizate. In plus ne propunem sa utilizam celulele stem CD117 pozitive in co-cultura cu celule endoteliale progenitoare izolate din sangele din cordonul ombilical pentru a investiga efectul regenerativ al acetora fara utilizare factorilor de crestere si a diferentierii *in vitro*, pentru a sustine o posibila strategie terapeutica cu aplicabilitate clinica.

SCIENTIFIC REPORT

Project title: Impact of high glucose in valvular endothelial cells-monocyte crosstalk: molecular signatures and role in early valvular dysfunction
Acronym: VALDYSIGN
Phase 1: Characterization of the molecular profile induced by short-term exposure to diabetic conditions in the VEC-monocyte interaction (part I)
Implementation period: 01.04.2022-31.12.2022

Activity 1.1: Sequencing the entire transcriptome to identify molecules involved in the early changes induced in VEC-monocyte interactions under diabetic conditions.
Activity 1.2: Validation of key molecules through Real Time PCR.

SUMMARY OF PHASE 1: Aortic valve disease (AVD) and diabetes are progressive diseases that represent global health problems. Diabetes is a risk factor for AVD, predicts a faster disease progression, and accelerates AVD. The early mechanisms of aortic valve dysfunction are still unclear, but valvular endothelial cells (VEC) and monocytes (Mo) play key roles in this process. The mechanisms by which diabetes contributes to early valve dysfunction are not yet well known, so our hypothesis is that high glucose alters the normal interaction of valvular endothelial cells with monocytes, inducing progressive molecular changes, phenotypic changes, and functional alterations in both cell types. The aim of the VALDYSIGN project is to highlight the modified molecules in VEC and Mo in their communication under HG conditions, to evaluate the role of key molecules in cell dysfunction, and to propose new mechanisms of early valvular dysfunction in diabetes.
In the first phase of the VALDYSIGN project, the molecular profile induced by short-term exposure to high glucose in the VEC-Mo interaction was characterized by sequencing the entire transcriptome of both cell types. Differentially expressed genes (DEGs) in different experimental conditions were functionally analyzed by association with available KEGG maps in databases. In VEC interacting with Mo under conditions of high glucose, molecules involved in focal adhesions, tight junctions, adherens junctions, cellular adhesion molecules, matrix-receptor interactions, cytoskeleton regulation and endothelial transmigration were identified, suggesting changes in endothelial permeability and cellular cytoskeleton changes. In addition, molecules involved in matrix-receptor interactions, transendothelial migration, cellular adhesion molecules, and signaling pathways TLR, NF-kB, JAK-STAT, TNFα and chemokines, suggesting increased monocytic adhesion and transmigration to the endothelium and an inflammatory phenotype, were identified in Mo interacting with VEC under high glucose conditions. These data suggest that early exposure to high glucose induces progressive molecular and phenotypic changes in both cell types, contributing to valvular dysfunction in diabetes.

DISSEMINATION: Participation at the XXXIX Annual Scientific Session of the Romanian Society of Cell Biology, October 21-23, 2022, Cluj-Napoca, Romania – MOLECULAR SIGNATURES OF

VALVULAR ENDOTHELIAL CELLS AND MONOCYTES CROSS-TALK IN EARLY DIABETIC CONDITIONS.
Monica Tucureanu, Letitia Ciortan, Ileana Manduteanu – poster.

SCIENTIFIC REPORT

Project title: Impact of high glucose in valvular endothelial cells-monocyte crosstalk: molecular signatures and role in early valvular dysfunction
Acronym: VALDYSIGN
Phase 2: Characterization of the molecular profile induced by short-term exposure to diabetic conditions in the VEC-monocyte interaction (part II); Evaluation of the function of relevant molecules found to be modified in endothelial permeability and monocyte adhesion and transmigration (part I).
Implementation period: 01.01.2023-31.12.2023
Activity 2.1: Investigation of protein expression of relevant molecules induced by high glucose in VEC-monocyte co-culture;
Activity 2.2: Investigation of endothelial permeability under high glucose conditions: the role of modified expression of junctional and cytoskeletal proteins;
Activity 2.3: Establishing the role of diabetes in monocyte adhesion and transmigration under dynamic conditions.

SUMMARY OF PHASE 2

Valvular endothelium represents an important protective barrier against metabolic, mechanical, and inflammatory aggression and is believed to play a role in valvular homeostasis and interactions with circulating blood cells and molecules. Regulation of endothelial barrier function is orchestrated by the quantity and arrangement of intercellular junctions, particularly adherens and tight junctions, of actin cytoskeleton organization and focal adhesions. Together, these elements govern tissue permeability. There is evidence that the phenotype of valvular endothelial cells (VEC) is progressively modified in diabetes, but the specific mechanisms by which diabetes contributes to early endothelial dysfunction remain incompletely elucidated. However, it is certain that both VEC and monocytes (Mo) play an important role and the diabetic environment perturbs cellular homeostasis. Therefore, the hypothesis of our study is that the interaction between monocytes and VEC under diabetic conditions triggers molecular modifications that lead to impairment of endothelial integrity and induction of monocyte adhesion and transmigration. The objective of this study is to establish the molecular signatures of VEC after their brief interaction with monocytes under high glucose conditions and to propose new mechanisms underlying early valvular dysfunction in diabetes.
In the second phase of the VALDYSIGN project, the gene and protein expression of modified molecules in VEC by interaction with monocytes under high glucose conditions were investigated, targeting the molecules involved in cell-ECM and cell-cell interactions, cell adhesion, and cytoskeleton regulation (pathways identified by VEC transcriptome sequencing analysis). The results showed that the interaction between VEC and monocytes under high glucose conditions modifies focal adhesions by decreasing focal adhesion kinase phosphorylation, reducing paxillin expression, vinculin internalization, and decreasing the expression of integrins that function as ECM receptors. In addition, VEC-monocyte interaction under high glucose conditions activates PI3K and RhoA-ROCK1 signaling pathways, reduces intercellular junctions by decreasing cadherin-2, increases E-selectin expression, and α4 integrin expression on the cell surface.
Since our study identified modifications of molecules involved in cell-cell and cell-ECM interactions, we investigated the functional role of these modifications in cellular permeability.

Our data showed that valvular endothelium permeability increases in interaction with monocytes under high glucose, compared to VEC maintained in culture medium with normal glucose concentration. Moreover, VEC interacting with monocytes under high glucose conditions are less adhesive to collagen I, fibronectin, and vitronectin, corresponding to observations on integrin expression. Also, our data suggest that increased glucose levels lead to increased monocyte adhesion and transmigration, which may contribute to the progression of aortic valve lesions.

DISSEMINATION

The results obtained in Phase 2 of the VALDYSIGN project were disseminated at two international conferences:

- Oral presentation: Bioinformatic analysis of molecular mechanisms underlying the aortic valvular dysfunction in diabetes. Monica Tucureanu. Participation in the "Crossing bridges between bioinformatics and clinical research - Genetoberfest GO2023" conference, from 16-19 October 2023, Munich, Germany;
- Poster: Molecular mechanisms underlying the aortic valvular dysfunction in diabetes. Monica Tucureanu, Letitia Ciortan, Razvan Macarie, Andreea Mihaila, Elena Butoi, Ileana Manduteanu. Participation in the 44th ANNUAL SCIENTIFIC SYMPOSIUM OF THE INSTITUTE OF CELLULAR BIOLOGY AND PATHOLOGY "NICOLAE SIMIONESCU" held jointly with the 40th ANNUAL SCIENTIFIC SESSION OF THE ROMANIAN SOCIETY FOR CELL BIOLOGY, from 16-17 November 2023, Bucharest, Romania.

SCIENTIFIC REPORT

Project title: Impact of high glucose in valvular endothelial cells-monocyte crosstalk: molecular signatures and role in early valvular dysfunction
Acronym: VALDYSIGN
Phase 3: Evaluation of the function of relevant molecules found to be modified in endothelial permeability and monocyte adhesion and transmigration (part II).
Implementation period: 01.01.2024-31.05.2024
Activity 2.3: Establishing the role of diabetes in monocyte adhesion and transmigration under dynamic conditions.

SUMMARY OF PHASE 3

In this study, our results reveal that the interaction between VEC and monocytes under normal or diabetic conditions has a significant impact on the transcriptomic profile of VEC. Specific molecular changes were identified in processes associated with cytoskeleton regulation, focal adhesion, cell junctions, and cell adhesion molecules. Exposure of VEC to increased glucose concentration led to changes in key molecules and regulatory proteins, such as increased expression of VASP and ROCK1 (involved in cytoskeleton regulation), increased expression of JAM2, cadherin-2, and integrins α4, α5 and β2 (involved in intercellular adhesion and cell-matrix interactions), and decreased expression of paxillin (an adaptive protein in focal adhesions). Additionally, the interaction between VEC and monocytes under normal glucose conditions resulted in increased expression of VASP, ROCK1, integrin β2, and PI3K activation, as well as decreased expression of proteins involved in focal adhesions (FAK and paxillin) and junctional proteins (claudin-5 and cadherin-5). In conditions of increased glucose, this interaction induced PI3K signaling pathway activation, decreased expression of junctional proteins (FAK, caveolin-1, and paxillin), and increased expression of E-selectin. Moreover, the interaction under high glucose conditions highlighted decreased expression of integrins α1, α5, αV, αVβ5, α5β1 and cadherin-2. These changes led to cytoskeleton disorganization, junctional complex alterations, decreased VEC adhesion to extracellular matrix proteins, increased permeability, and increased monocyte adhesion and transmigration, suggesting the alteration of the valvular endothelium's barrier function.
To determine the mechanisms involved in regulating the barrier function, we used Y27623 and LY294002 inhibitors for ROCK and PI3K pathways, identified as activated under diabetic conditions or after monocyte interaction. ROCK and PI3K signaling pathways were identified as activated in VEC under diabetic conditions or after interaction with monocytes. The results show the partial involvement of these signaling pathways in cytoskeleton regulation, regulation of focal adhesion formation or disassembly, intercellular junction regulation, and regulation of cell adhesion molecule expression. Furthermore, PI3K was shown to be involved in regulating endothelial permeability. All of these findings demonstrate that both ROCK and PI3K play an important role in regulating mechanisms induced by increased glucose in the monocyte-VEC interaction and can be potential therapeutic targets in aortic valve disease associated with diabetes.

	Fikadu Tafesse, Oregon Health and Science University, USA Vaccine and natural infection elicited COVID-19 immunity against SARS-CoV-2 variants *(This talk will be given at the end of the Session 4)*
13.35 – 14.30	**Lunch and poster session**

	SESSION 3 **NON-COMMUNICABLE DISEASES: ATHEROSCLEROSIS AND DIABETES** **14.30 – 16.25*** **Chairs: Anca Sima, Maria Dorobantu** * *The speakers are kindly asked to leave time for questions and discussion*
14.30 – 14.55	**Maria Dorobantu,** Floreasca Clinical Emergency Hospital, Bucharest, Romania Genetic aspects in hypertrophic cardiomyopathy: what is new?
14.55 – 15.15	**Camelia Stancu,** ICBP-NS New biomarkers for risk stratification in peripheral artery disease patients – proteins of dysfunctional HDL
15.15 – 15.30	**Viorel Suica,** ICBP-NS Cardiac alarmins as indicators of the efficacy of hypolipidemic treatment in experimental hyperlipidemia
15.30-15.45	**Laura Toma,** ICBP-NS Endothelial dysfunction in diabetes is aggravated by glycated lipoproteins; novel molecular therapies
15.45 – 16.00	**Violeta Trusca,** ICBP-NS Understanding the apolipoprotein E gene regulation, a key step toward the development of novel therapies for atherosclerosis
16.00 – 16.25	**Anca Dobrian,** Eastern Virginia Medical School, USA Learning to listen: understanding extracellular vesicle chatter in obesity co-morbidities
16.25 – 17.00	Coffee break
	SESSION 4 - PhD STUDENTS' PRESENTATIONS **NON-COMMUNICABLE DISEASES: ATHEROSCLEROSIS, DIABETES AND CANCER** **17.00 – 18.10*** **Chairs: Alexandrina Burlacu, Carmen Cotrutz** * *The speakers are kindly asked to leave time for questions and discussion*
17.00 - 17.10	**Vasile Grecu,** "Grigore T. Popa" Univ. of Medicine, Iasi, Romania The importance of determining and corelating the expression of VEGFR-1, CD4, and CD8 in the evaluation of acute rejection of cardiac allografts – correlative immunohistochemical study

17.10 – 17.20	**Teodora Barbalata**, ICBP-NS MicroRNAs profiling in the heart and liver of high-fat diet induced hyperlipidemic hamster
17.20 - 17.30	**Alexandra Lazar**, ICBP-NS Activation of histone acetyltransferase p300/CBP - dependent signalling pathways induces oxidative stress, inflammation, and fibrosis in the kidney of diabetic mice
17.30 – 17.40	**Evelyn Rusu**, ICBP-NS MiRNAs generated from Meg3-Mirg locus are downregulated during aging
17.40 – 17.50	**Ioana Karla Comarita**, ICBP-NS Therapeutic potential of stem cell- derived extracellular vesicles on atherosclerosis-induced vascular dysfunction
17.50 - 18.00	**Maria Anghelache**, ICBP-NS Preparation and characterization of macrophage-membrane-coated nanoemulsions for delivery of specialized pro-resolving lipid mediators of inflammation
18.00 – 18.10	**Botezatu Ionut Catalin**, "Grigore T. Popa" Univ. of Medicine, Iasi Expression of MT1-MMP and CD147 in gingival tissue of patients with diabetes mellitus-corelative immunohistochemical study

Friday - November 5, 2021	
	SESSION 5 **CELLULAR DYNAMICS IN DISTRESS AND DISEASE** **9.30 – 11.05*** **Chair: Anca Gafencu** * *The speakers are kindly asked to leave time for questions and discussion*
09.30 - 10.00	**Stefan Constantinescu**, Catholic Univ. of Louvain, Belgium Clonal hematopoietic driver and epigenetic mutations in myeloid cancers: relevance beyond hematology
10.00 - 10.25	**Shlomo Sasson**, The Hebrew University of Jerusalem, Israel Monounsaturated fatty acids protect insulin-secreting beta cells against free fatty acid-induced cytotoxicity

10.25 - 10.50	**Simona Chera,** University of Bergen, Norway Mapping islet cell interconversion phenomena
10.50 - 11.05	**Mirel Adrian Popa,** ICBP-NS The role of FGFR2 signalling in modulating MMP/TIMP balance in cardiac myofibroblasts
11.05 – 11.30	**Coffee break**
	SESSION 6 **THE ANNUAL GENERAL MEETING OF RSCB MEMBERS - REPORTS OF THE PRESIDENTS OF THE SOCIETY BRANCHES** **11.30 – 13.00** **Chair: Maya Simionescu**
	Antoaneta Chesca, President RSCB - Brasov Branch **Carmen- Elena Cotrutz,** President RSCB - Iasi Branch **Anca Hermenean,** President RSCB - Arad Branch **Catalina Pisoschi,** President RSCB - Craiova Branch **Daciana Sava,** President RSCB - Constanta Branch **Anca Ileana Sin,** President RSCB - Targu Mures Branch **Doina Verdes,** President RSCB - Timisoara Branch **TBA,** President RSCB - Cluj Branch **Maria Tolbaru,** Accountant of RSCB
13.00 – 13.40	**Lunch and poster session**
	SESSION 7 **PhD STUDENTS' PRESENTATIONS** **CELLS AND CELLULAR DERIVATIVES IN THERAPY** **13.40 – 15.10*** **Chairs: Felicia Antohe, Anca Hermenean** * *The speakers are kindly asked to leave time for questions and discussion*
13.40 - 13.50	**Daniela-Madalina Iacomi,** ICBP-NS Generation and characterization of an immortalized human adipose-derived mesenchymal stromal cell line
13.50 - 14.00	**Laura Maria Daian**, ICBP-NS Living under stress - Evaluating changes in β cells homeostasis

14.00 - 14.10	**Aurel Cerveanu –Hogas,** ICBP-NS Use of exosomal protein cargo for the prediction and management of gestational diabetes mellitus
14.10 - 14.20	**Raluca Tutuianu**, ICBP-NS Human mesenchymal stromal cells - derived exosomes promote skin wound healing; mechanisms involved
14.20 – 14.30	**Cristina-Andreea Mihaila,** ICBP-NS Polarized N1 and N2 neutrophils acquire distinct phenotypes and functions
14.30 – 14.40	**Neli Olah,** "Vasile Goldis" Western University of Arad, Romania Morpho-anatomical and phytochemical study of the Corylus L. species (buds)
14.40 - 14.50	**Rebeca Simona Ignat,** University of Bucharest Antifibrotic effects of Corylus avellana gemmotherapic extract reinforced with chrysin/cyclodextrin nanocomplexes on hepatic stellate cells
14.50 - 15.00	**Letitia Ciortan**, ICBP-NS High glucose induced changes in valvular endothelial cells phenotype in a 3D model of aortic valve disease
15.00 – 15.10	**Geanina Voicu,** ICBP-NS VCAM-1 targeted lipopolyplexes carrying Runx2-shRNA mitigate the osteodifferentiation of 3D-cultured human valvular interstitial cells
15.10 – 15.40	**Coffee break**
	SESSION 8 **CARDIOMYOPATHY, INFLAMMATION-RESOLUTION, ATHEROSCLEROSIS** **15.40 – 17.25*** **Chairs: Elena Butoi, Carmen Cotrutz** * *The speakers are kindly asked to leave time for questions and discussion*
15.40 – 16.05	**Alexandru Schiopu**, Lund University, Sweden The S100A8/A9 alarmin as potential treatment target in inflammatory cardiomyopathies

16.05 – 16.30	**Maria Consiglia Trotta,** "Luigi Vanvitelli" Univ. of Campania, Italy Resolvin D1 actions in ocular pathologies
16.30 – 16.55	**Elena Butoi,** ICBP-NS Polarized neutrophils: versatile players that orchestrate healing or heart failure after myocardial infarction
16.55 - 17.10	**Monica Tucureanu,** ICBP-NS Cellular and molecular mechanisms of complement proteins in human atherosclerotic plaque progression
17.10 - 17.25	**Loredan Nicolescu,** ICBP-NS Epigenetic biomarkers for peripheral artery disease
17.25 - 17.45	**Coffee break**
	SESSION 9 **GENERAL PATHOLOGY - CELLULAR AND MOLECULAR LEVEL** **17.45 – 18.50*** **Chair: Ileana Manduteanu** * *The speakers are kindly asked to leave time for questions and discussion*
17.45 – 18.10	**Dan Simionescu,** Clemson University, USA Non surgical management of abdominal aortic aneurysms
18.10 – 18.35	**Florea Lupu,** Oklahoma Medical Research Foundation, USA Coagulopathy and endotheliopathy of bacterial and viral infections
18.35 – 18.50	**Doinita Temelie- Olinici,** "Grigore T. Popa" Univ. of Medicine, Iasi Ultrastructural characteristics of keratoachantoma – clinical implications

Saturday - November 6, 2021	
	SESSION 10 **INNOVATIVE THERAPIES, STEM CELLS** **9.30 - 11.05*** **Chair: Manuela Calin** * *The speakers are kindly asked to leave time for questions and discussion*
9.30 – 9.55	**Manuela Calin,** ICBP-NS P-Selectin directed RAGE-shRNA nanocarriers reduce atherosclerosis-associated inflammation in ApoE-deficient mice
9.55 – 10.20	**Luiza Ghila,** University of Bergen, Norway Modelling pancreatic islet architecture using human induced pluripotent stem cells
10.20 – 10.45	**Ferenc Fenyvesi,** University of Debrecen, Hungary Application of cyclodextrins and calixarenes in the nanoformulations of bioactive compounds
10.45 – 11.05	**Bogdan Preda,** ICBP-NS Local microenvironment activates in vivo apoptosis of mesenchymal stromal cells after transplantation
11.05 – 11.30	**Coffee break**
	SESSION 11 **CELLULAR MODIFICATIONS UNDER STRESS** **11.30 – 13.30*** **Chairs: Gallia Butnaru, Larisa Andronic** * *The speakers are kindly asked to leave time for questions and discussion*
11.30 – 11.55	**Larisa Andronic,** IGPPP Chisinau, Republic of Moldova Cells and biotic stress in plant virus-host systems
11.55 – 12.20	**Mihaela Corneanu**, USAMVB Timisoara, Romania Cyto and genotoxicity of soil and water pollutants

12.20- 12.45	**Tatiana Saltanovici,** IGPPP Chisinau, Republic of Moldova Associated influence of viral pathogens and high temperature on male tomato gametophyte
12.45 – 13.00	**Miruna Stan**, Faculty of Biology Bucharest In vitro research on the anti-cancer potential of some curcumin derivates
13.00 -13.15	**Ana Emanuela Botez,** "Grigore T. Popa" Univ. of Medicine, Iasi β–Defensin and COX-2 expression value in premalignant epithelial lesions: correlative immunohistochemical study
13.15 – 13.30	**Pavel Onofrei,** "Grigore T. Popa" Univ. of Medicine, Iasi Expression value of MMP-14 and EMMPRIN (CD 147) in benign prostatic hyperplasia – comparative immunohistochemical study
13.30 – 14.00	**Lunch and poster session**
	ROUND TABLE **CELLULAR MODIFICATIONS UNDER STRESS** **14.00 - 16.00** **Organiser: Gallia Butnaru**
	Larisa Andronic, IGPPP Chisinau **Mihaela Corneanu,** USAMVB Timisoara **Ioan Sarac,** USAMVB Timisoara **Sorina Popescu,** USAMVB Timisoara **Violeta Turcus,** USAMVB Timisoara **Diana Argherie,** USAMVB Timisoara **Cristina Popescu,** "Vasile Goldis" Western University of Arad **Viviane Bota,** "Vasile Goldis" Western University of Arad
16.00 – 16.30	**CLOSING REMARKS**

INTERNATIONAL CONFERENCE

under the aegis of the **ROMANIAN ACADEMY**

THE 42nd ANNIVERSARY SYMPOSIUM OF THE INSTITUTE OF CELLULAR BIOLOGY AND PATHOLOGY "NICOLAE SIMIONESCU"

held jointly with

THE 38th ANNUAL SCIENTIFIC SESSION OF THE ROMANIAN SOCIETY FOR CELL BIOLOGY

"From basic cell biology to personalized medicine during Covid-19 pandemic; creativity and vision in a rapidly changing world"

November 4-6, 2021

VIRTUAL EVENT

Thursday - November 4, 2021	
OPENING OF THE CONFERENCE **9.30 – 9.45** Acad. Maya Simionescu – Director ICBP-NS and President RSCB Acad. Ioan-Aurel Pop – President of the Romanian Academy Prof. Dr. Adrian Curaj – Director of UEFISCDI	
	SESSION 1 **ICBP-NS CONFRONTING THE SARS-CoV-2 PANDEMIC ERA** **Chair: Maya Simionescu** **9.45 - 12.00**
	Maya Simionescu (Director) Uncovering the cell's secrets - a continuous quest of our team **Ileana Manduteanu** (Dept. of Biopathology and Therapy of Inflammation) Mechanisms and novel therapies for aortic valve disease in diabetes **Manuela Calin** (Lab. of Medical and Pharmaceutical Bionanotechnologies) Targeted therapies based on nanocarriers to reduce vascular inflammation **Anca Sima** (Dept. of Lipidomics) In search for new biomarkers for cardiovascular diseases - dysfunctional HDL and epigenetic factors (miRNAs). **Felicia Antohe** (Dept. of Proteomics) Moving forward towards proteomics-based precision medicine in non-communicable diseases **Anca Gafencu** (Lab. of Gene Regulation and Molecular Therapies) Cellular and molecular manipulations for therapeutic purposes **Alexandrina Burlacu** (Lab. of Stem Cell Biology) Harnessing the power of MSC to attenuate the damaging effects of aging, autoimmune diseases and myocardial infarction

	Adrian Manea (Molecular and Cellular Pharmacology - Functional Genomics Laboratory) Epigenetic mechanisms in cardiometabolic disorders: potential biomarkers and therapeutic targets **Irina Titorencu** (Cell and Tissue Engineering Laboratory) Mesenchymal stromal cells: therapeutic potential for skin wound healing
12.00 - 12.30	**Coffee break**
	SESSION 2 **SARS-CoV-2 – INFECTION / INVASIVENESS / VACCINE** **12.30 – 14.00*** **Chair: Maya Simionescu** * *The speakers are kindly asked to leave time for questions and discussion*
12.30 - 12.50	**Maya Simionescu**, ICBP-NS Dangerous encounters: SARS-CoV-2 - epithelial/ endothelial cell (Intalniri periculoase: SARS-CoV-2 - celula epiteliala/ endoteliala)
12.50 - 13.20	**Victor Voicu**, Vice-President of the Romanian Academy Neuroinvazia virusului SARS-CoV-2, simptomatologie, cai de patrundere si mecanisme patogenice (Neuroinvasion of SARS-CoV-2 virus, symptomatology, penetration routes and pathogenic mechanisms)
13.20 - 13.35	**Gafincu Grigoriu Daniel- Ionut,** "Grigore T. Popa" University of Medicine, Iasi, Romania SARS-CoV-2 UVC inactivation-mechanisms and a new air decontamination equipment
	Fikadu Tafesse, Oregon Health and Science University, USA Vaccine and natural infection elicited COVID-19 immunity against SARS-CoV-2 variants *(This talk will be given at the end of the Session 4)*
13.35 – 14.30	**Lunch and poster session**

	SESSION 3 **NON-COMMUNICABLE DISEASES: ATHEROSCLEROSIS AND DIABETES** **14.30 – 16.25*** **Chairs: Anca Sima, Maria Dorobantu** * *The speakers are kindly asked to leave time for questions and discussion*
14.30 – 14.55	**Maria Dorobantu,** Floreasca Clinical Emergency Hospital, Bucharest, Romania Genetic aspects in hypertrophic cardiomyopathy: what is new?
14.55 – 15.15	**Camelia Stancu,** ICBP-NS New biomarkers for risk stratification in peripheral artery disease patients – proteins of dysfunctional HDL
15.15 – 15.30	**Viorel Suica,** ICBP-NS Cardiac alarmins as indicators of the efficacy of hypolipidemic treatment in experimental hyperlipidemia
15.30-15.45	**Laura Toma,** ICBP-NS Endothelial dysfunction in diabetes is aggravated by glycated lipoproteins; novel molecular therapies
15.45 – 16.00	**Violeta Trusca,** ICBP-NS Understanding the apolipoprotein E gene regulation, a key step toward the development of novel therapies for atherosclerosis
16.00 – 16.25	**Anca Dobrian,** Eastern Virginia Medical School, USA Learning to listen: understanding extracellular vesicle chatter in obesity co-morbidities
16.25 – 17.00	Coffee break
	SESSION 4 - PhD STUDENTS' PRESENTATIONS **NON-COMMUNICABLE DISEASES: ATHEROSCLEROSIS, DIABETES AND CANCER** **17.00 – 18.10*** **Chairs: Alexandrina Burlacu, Carmen Cotrutz** * *The speakers are kindly asked to leave time for questions and discussion*
17.00 - 17.10	**Vasile Grecu,** "Grigore T. Popa" Univ. of Medicine, Iasi, Romania The importance of determining and corelating the expression of VEGFR-1, CD4, and CD8 in the evaluation of acute rejection of cardiac allografts – correlative immunohistochemical study

17.10 – 17.20	**Teodora Barbalata**, ICBP-NS MicroRNAs profiling in the heart and liver of high-fat diet induced hyperlipidemic hamster
17.20 - 17.30	**Alexandra Lazar**, ICBP-NS Activation of histone acetyltransferase p300/CBP - dependent signalling pathways induces oxidative stress, inflammation, and fibrosis in the kidney of diabetic mice
17.30 – 17.40	**Evelyn Rusu**, ICBP-NS MiRNAs generated from Meg3-Mirg locus are downregulated during aging
17.40 – 17.50	**Ioana Karla Comarita**, ICBP-NS Therapeutic potential of stem cell- derived extracellular vesicles on atherosclerosis-induced vascular dysfunction
17.50 - 18.00	**Maria Anghelache**, ICBP-NS Preparation and characterization of macrophage-membrane-coated nanoemulsions for delivery of specialized pro-resolving lipid mediators of inflammation
18.00 – 18.10	**Botezatu Ionut Catalin**, "Grigore T. Popa" Univ. of Medicine, Iasi Expression of MT1-MMP and CD147 in gingival tissue of patients with diabetes mellitus-corelative immunohistochemical study

Friday - November 5, 2021	
	SESSION 5 **CELLULAR DYNAMICS IN DISTRESS AND DISEASE** **9.30 – 11.05*** **Chair: Anca Gafencu** * *The speakers are kindly asked to leave time for questions and discussion*
09.30 - 10.00	**Stefan Constantinescu**, Catholic Univ. of Louvain, Belgium Clonal hematopoietic driver and epigenetic mutations in myeloid cancers: relevance beyond hematology
10.00 - 10.25	**Shlomo Sasson**, The Hebrew University of Jerusalem, Israel Monounsaturated fatty acids protect insulin-secreting beta cells against free fatty acid-induced cytotoxicity

10.25 - 10.50	**Simona Chera,** University of Bergen, Norway Mapping islet cell interconversion phenomena
10.50 - 11.05	**Mirel Adrian Popa,** ICBP-NS The role of FGFR2 signalling in modulating MMP/TIMP balance in cardiac myofibroblasts
11.05 – 11.30	**Coffee break**
	SESSION 6 **THE ANNUAL GENERAL MEETING OF RSCB MEMBERS - REPORTS OF THE PRESIDENTS OF THE SOCIETY BRANCHES** **11.30 – 13.00** **Chair: Maya Simionescu**
	Antoaneta Chesca, President RSCB - Brasov Branch **Carmen- Elena Cotrutz,** President RSCB - Iasi Branch **Anca Hermenean,** President RSCB - Arad Branch **Catalina Pisoschi,** President RSCB - Craiova Branch **Daciana Sava,** President RSCB - Constanta Branch **Anca Ileana Sin,** President RSCB - Targu Mures Branch **Doina Verdes,** President RSCB - Timisoara Branch **TBA,** President RSCB - Cluj Branch **Maria Tolbaru,** Accountant of RSCB
13.00 – 13.40	**Lunch and poster session**
	SESSION 7 **PhD STUDENTS' PRESENTATIONS** **CELLS AND CELLULAR DERIVATIVES IN THERAPY** **13.40 – 15.10*** **Chairs: Felicia Antohe, Anca Hermenean** * *The speakers are kindly asked to leave time for questions and discussion*
13.40 - 13.50	**Daniela-Madalina Iacomi,** ICBP-NS Generation and characterization of an immortalized human adipose-derived mesenchymal stromal cell line
13.50 - 14.00	**Laura Maria Daian**, ICBP-NS Living under stress - Evaluating changes in β cells homeostasis

14.00 - 14.10	**Aurel Cerveanu –Hogas,** ICBP-NS Use of exosomal protein cargo for the prediction and management of gestational diabetes mellitus
14.10 - 14.20	**Raluca Tutuianu**, ICBP-NS Human mesenchymal stromal cells - derived exosomes promote skin wound healing; mechanisms involved

Scientific report

Project code: PN-III-P1-1.1-PD-2016-1903/ Contract number: 133PD/2018
Stage nr. 1 / 2018

„Interference with hypoxia-signalling pathways in mesenchymal stem cells prior to transplantation as a strategy to enhance myocardial recovery post infarction"

Summary:

Mesenchymal stem cells (MSC) derived from bone marrow reside *in vivo* in a low oxygen microenvironment (1-5% O_2). However, *in vitro* standard cell culture protocols are performed at atmospheric concentrations of oxygen (21% O_2), which are restrictive growth conditions with selection effects through long-term cultivation by accumulation of loss-of-function mutations that cause cells to escape from the oxygen-induced inhibition growth (Boregowda et al., Stem Cells 2012).

The goal of this project is to better understand the role of hypoxia and more specific of MIR210HG locus on the effector properties of bone marrow-derived human MSC.

The main results obtained at this stage of the project are:

1. Characterization of human bone-marrow derived MSC grown for long-term (three passages) in normoxia (21% oxygen) or hypoxia (5% oxygen). For hypoxia experiments, cells where cultivated within a controlled and sustained workstation environment using the Whitley H35 Hypoxystation. The results showed that low oxygen concentration (5% O_2) slightly increased the proliferation index and cell number, as compared with normoxia (21% O_2).
2. Assessing the metabolic phenotype of MSC as compared to that of another cell type, namely endothelial progenitor cells (EPC) isolated from human umbilical cord blood. This analysis was performed using an Agilent Seahorse XFp system. The results showed that MSC have a more energetic metabolism than EPC, both in basal and stress conditions. Under conditions that mimic hypoxia (with DMOG) both cell types become glycolytic. However, EPC lose any stress response capacity while MSC still have a metabolic activation capacity. Their coculture both under normal conditions and in the presence of DMOG, shows a metabolic response capacity, suggesting that MSC confer an advantage for EPC-based cell therapy when co-transplanted at an ischemic tissue injury.
3. Functional evaluation for the deletion of MIR210HG locus by Real Time PCR for miR-210 and lnc MIR210HG transcripts -001 and -003 expression and by functional metabolic analysis of glycolysis and mitochondrial respiration in control cells and knock-out cells. The results showed that by using CRISPR-Cas9 genome editing technology, the deletion of MIR210HG locus resulted in a decrease in the expression for the MIR210HG ncRNA transcripts with functional impact on the metabolic phenotype of the cells (affecting the mitochondrial respiration).

Date: 04.12.2018

Dr. Mihai Bogdan Preda

Scientific report

Project code: PN-III-P1-1.1-PD-2016-1903/ Contract number: 133PD/2018
Stage nr. 2 / 2019

„Interference with hypoxia-signalling pathways in mesenchymal stem cells prior to transplantation as a strategy to enhance myocardial recovery post infarction"

Summary:

Hypoxia-responsive ncRNAs have yet undefined roles in the biology of mesenchymal stem cells (MSCs). Currently regarded as a "master hypoxamiR" with complex roles in the cellular responses to hypoxia, miR-210 was first discovered by Dr. Mircea Ivan's group (Kulshreshtha et al., Mol Cell Biol 2007) and demonstrated to be induced in response to low oxygen concentrations. As miR-210 improved angiogenesis, inhibited apoptosis, and improved cardiac function in a murine model of myocardial infarction (Hu et al., Circulation 2010), this fundamental regulator of hypoxia might have other yet unknown functions, which extends beyond cell response to hypoxia.

The goal of this project is to improve the pro-angiogenic, anti-inflammatory and immunomodulatory (effector) functions of MSC by manipulating the hypoxia-responsive mechanisms in order to consolidate their therapeutic potential for post-infarction myocardial regeneration.

The main results obtained at this stage of the project are:

1. Our results showed that long-term cultivation (3 weeks) of human MSCs at low O_2 concentrations (3% or hypoxia) have significantly lowered the proliferative capacity of the cells, measured by real-time monitoring of proliferation (xCELLigence), cumulative population doublings, and colony-forming unit fibroblast assay. There are conflicting reports on the effects of low O_2 levels (hypoxia) on MSCs proliferation in vitro. Some studies have shown that MSCs proliferate better when grow at low concentrations of O_2 but others have shown the harmful effect of hypoxia. A possible explanation of this response observed by us would be that the cells were derived and cultured for several passages (3-5) first at the atmospheric concentration of O_2 and thus adapted to this atmospheric microenvironment. Moreover, hypoxia reduced cell proliferation without disturbing the mitochondrial function of MSCs.
2. Adaptation of human MSCs to hypoxia (for 10 days) resulted in increased pro-angiogenic properties (measured by Proteome Profiler Human XL Cytokine Array) and in similar immunomodulatory effect on activated lymphocytes, as normoxic MSC. However, hypoxic MSCs attenuate M1 (pro-inflammatory) activation and enhance M2 (reparatory) activation of THP-1 derived macrophages at a higher level as compared with normoxic MSCs.
3. Gain-of-function and loss-of-function experiments of miR210 expression in human MSC cultivated in normoxic (atmospheric) conditions or short-term exposed to hypoxia (3% O_2) showed that the hypoxia-responsive ncRNA miR210 largely recapitulates the effects of hypoxia. Thus, activation of hypoxia-induced signalling pathways in hMSCs grounds them to increase their pro-angiogenic and anti-inflammatory potential, having a particular importance in MSC-based cell therapy.

Scientific report

Project code: PN-III-P1-1.1-PD-2016-1903/ Contract number: 133PD/2018
Stage nr. 3 / 2020

„Interference with hypoxia-signalling pathways in mesenchymal stem cells prior to transplantation as a strategy to enhance myocardial recovery post infarction"

Summary:

The OXI-SCENARIO project aimed to improve the effector properties of human mesenchymal stromal cells (MSCs) by *in vitro* targeting of cellular mechanisms of response to hypoxia (low non-physiological oxygen concentration) and to evaluate the therapeutic potential of hypoxia-signalling modulated cells in a preclinical experimental model of mouse with myocardial infarction (MI).

In the last objective we evaluated the role of miR210 locus on the regenerative capacity and migration of MSCs in mice with MI. Our data from gain-of-function and loss-of-function experiments indicated that:

- MiR210 positively modulates MSCs survival after intravenous cell transplantation in mice with myocardial infarction;

- Transplantation of MSCs overexpressing miR210 improved cardiac function by reducing myocardial cell apoptosis in MI border zones and increasing the percentage of immune cell sub-populations involved in the myocardial repair post-infarction (M2 macrophages, and Treg lymphocytes).

Scientific Report (December 2018 — December 2019)
Project PN-III-P1-1.1-PD-2016-1942

"Evaluation of the therapeutic potential of non-viral apolipoprotein E gene transfer to limit progression of atherosclerosis"

In the frame of the project **PD20/2018 PN-III-P1-1.1-PD-2016-1942** entitled: **„Evaluation of the therapeutic potential of non-viral apolipoprotein E gene transfer to limit progression of atherosclerosis"** in the period December 2018 – December 2019, we performed the experiments planned in the following activity:

A 2.1: Determine the organs transfected by systemic delivery of C60-apoE/GFP polyplexes. Test the time-course evolution of *in vivo* transfection using these polyplexes.

Apolipoprotein E (apoE) has lipid-lowering and anti-atherosclerotic effects, being involved in the clearance of cholesterol-rich lipoproteins and the cholesterol efflux from cells. Our hypothesis is that an increase in apoE expression induced by fullerene-based nanosystems confer anti-atherosclerotic protection. The goal of this proposal is to generate fullerene-based nanoparticles conjugated with DNA encoding full-length or truncated forms of apoE under CMV promoter to be used for *in vivo* non-viral transfection as a therapeutic tool for limiting atherosclerosis progression. The specific objectives are:

1. To generate non-viral transfection agents for expression of apoE3 or its fragments. We accomplished this objective by cloning apoE3 and its N- and C- terminal regions in pcDNA3.1-DYK vector and then the obtained plasmids were linked to C60-PEI conjugates. We confirmed the functionality of C60-PEI-DNA polyplexes as non-viral transfection agents.
2. To assess the timing and organs accumulation of apoE expression after *in vivo* transfection. We accomplished this objective; we determined the organs transfected by systemic delivery of C60-PEI-DNA polyplexes and we tested the time-course evolution of *in vivo* transfection with these polyplexes.

To identify the organs that were efficiently transfected by systemic administration of nanoparticles and to determine the time course of *in vivo* transfection, C57Bl6 mice were injected with C60-PEI polyplexes and DNA encoding: (**A**) apoE3 (pcDNA3.1-DYK-apoE3) or (**B**) luciferase (pGL3-CMV-LUC). (**A**). Two and five days after *in vivo* transfection of mice with C60PEI-apoE polyplexes, human apoE gene expression was detected by RT-PCR. For this, various organs were harvested from the injected mice and homogenized in TRIzol. The RNA isolated was subjected to DNase treatment and reverse-transcribed into cDNA. The mRNA expression of human apoE gene was detected by PCR amplification with specific primers. (B). The signal emitted by luciferase was monitored daily using the XenoLight D-Luciferin substrate and IVIS Spectrum *In Vivo* Imaging System (PerkinElmer). The results showed that the strongest signal for luciferase was detected in liver, lung and spleen two days after systemic administration of C60-PEI-DNA nanoparticles. Thus, by RT-PCR (A) or by using IVIS Spectrum *In Vivo* Imaging System (B), we determined the organs efficiently transfected with C60-PEI-DNA polyplexes and we tested the time-course evolution of *in vivo* transfection using these polyplexes.

In conclusion, the results obtained in this project showed that C60PEI-DNA polyplexes can be successfully used for *in vivo* transfection. The results obtained within the project are part of a manuscript in preparation.

Dissemination

The results obtained this year within the project were presented as posters at the following scientific events:

- "***Fullerene-based nanoparticles conjugated with apolipoprotein E encoding DNA for gene therapy purposes***", Violeta G. **Trusca**, Ioana M. Fenyo, Mădălina Dumitrescu, Mariana Pinteala, Anca V. Gafencu, poster presented at "The 11th National Congress with International Participation and The 37th Annual Scientific Session of the Romanian Society of Cell Biology", Constanta, June, 2019. This poster received „Special Mention - Award".
- "**Optimization** ***of transfection using fullerene-based nanoparticles for gene therapy purposes***", Violeta G. **Trusca**, Ioana M. Fenyo, Mădălina Dumitrescu, Mariana Pinteala, Anca V. Gafencu, poster presented at Annivrsary Simposium of IBPC "N. Simionescu", " A fascinating journey of 40 years to discover the secrets of the cell for the benefit of human health" - Institute of Cellular Biology and Pathology „Nicolae Simionescu", Romanian Academy, Bucharest, 19-20 September 2019.

Prezentare Proiect CARDIOPRO

Institutul de Biologie si Patologie Celulara “Nicolae Simionescu” (IBPC-NS) este un centru de cercetare fundamentala al Academiei Romane, cu experienta de 33 de ani in studiul la nivel celular si molecular al sistemului cardiovascular in conditii normale si patologice, cu precadere a maladiilor majore care afecteaza grav societatea moderna: ateroscleroza, diabet, obezitate si disfunctiile neurovasculare.

Scopul proiectului:

Extinderea si modernizarea infrastructurii de cercetare in domeniul cardio-diabetologiei in vederea accelerarii rezultatelor stiintifice si a transferului lor din laborator in clinica - medicina translationala.

Aceasta va contribui la cresterea capacitatii de cercetare a echipei IBPC-NS, cu consecinte in profilaxia si imbunatatirea tratamentului bolilor cardiovasculare cat si asupra nivelului de competitivitate a stiintei Românesti si integrarea in Aria Europeana de Cercetare.

Obiectivele proiectului:

1) **Cresterea calitatii si competitivitatii cercetarii** prin achizitionarea de echipamente noi in vederea introducerii tehnologiilor moderne, competitive pe plan European. Dotarea laboratoarelor a fost facuta astfel incat sa sustina noi directii de cercetare in cardio-diabetologie: lipidomica, proteomica, genomica-transcriptomica si terapie moleculara, patofiziologie si farmacologie, biopatologia si terapia inflamatiei si medicina regenerativa.

2) **Promovarea tehnologiilor de virf** in cercetarea orientata pentru prevenirea si tratarea maladiilor cardiovasculare si diabezitate, cercetare menită să contribuie la modernizarea actului medical si prin aceasta la scaderea incidentei grave a mortalitatii prin boli cardiovasculare.

3) **Integrarea IBPC-NS in Aria Europeana de Cercetare** prin intarirea relatiilor de colaborare existente, nationale si internationale.

4) **Valorificarea integrala si extinderea potentialului uman din IBPC-NS**: atragerea de tineri cercetatori, crearea de noi locuri de munca, reducerea „brain-drain”.

5) **Dezvoltarea institutională** bazata pe strategia de dezvoltare existentă a institutului şi elaborarea unui plan de actiuni pe termen scurt, mediu si lung; profesionalizarea managementului cercetării şi consolidării rolului ştiinței în societate.

Keywords: inflammation, acute inflammation, chronic inflammation, cytokines, chemokines, endothelial cells, human vascular smooth muscle cells, monocytes / macrophages, cell adhesion molecules, apoE-deficient mice, adhesion, transmigration, nanotherapy, nanocarriers, lipid nanoparticles, liposomes , chemokine receptor antagonists, resistin, MAPKinases, clodronate, apoptosis.

Inflammation is a mechanism of the innate immune system as part of a complex biological response of vascular tissue to harmful stimuli (pathogens, damaged cells, irritants). The end result of the inflammatory process is to protect the body by infection and to restore the structure and function of damaged tissues. Inflammation may be un acute reaction, resulting in the elimination of inflammatory stimuli and tissue recovery in physiological conditions, or may be chronic reaction leading to exacerbation and the developing of various pathologies, depending on the reaction severity. Chronic inflammation is involved in numerous pathologies including atherosclerosis, cancer, rheumatoid arthritis, multiple sclerosis, inflammatory bowel disease, Alzheimer's, lupus, allergies, etc..

Activated endothelium has an important role in the inflammatory. Under normal conditions, the vascular endothelium is non-thrombogenic and non-sticky. Changes in the microenvironment affects endothelial cells that will express adhesion molecules (VCAM-1, ICAM-1, E-and P-selectin, fractalkina), which determine leucocytes and platelets recruitement and adhesion by their corresponding receptors. In addition to adhesion molecules, chemokines such as MCP-1 (CCL2), RANTES (CCL5), fractalkina (CX3CL1) express by endothelial cells bind to receptors on the surface of leukocytes and with adhesion molecules contribute to their adhesion and transmigration. Chemokines bind to glycosaminoglycans present on the endothelial cell membrane and guide the entry of leukocytes into arterial wall. Monocytes are attracted by CCL2, CCL5 and CX3CL1 that activate their receptors CCR2, CCR5 and CX3CR1 on monocytes.

Due to the involvement of cellular adhesion molecules and chemokines in the development of chronic inflammatory diseases, therapeutic intervention lead to new opportunities in prevention and treatment of these diseases. Functional manipulation of chemokine system, such as inhibition of chemokine / chemokine receptors interaction using chemokine antagonists (CA) or chemokine receptor antagonists (CRA), could be an important therapeutic option to prevent the inflammatory cells accumulation and diseases progress (atherogenesis, metastasis). An approach to modulate drug targeting to a specific site is to design transport vehicles able to "deliver" the drug in the cell and to recognize targeted

molecules. The most promising for targeting to specific sites of nanotransporters is the attachment of ligands on their surface able to carry the active substance in the cell or to recognize specific target molecules.

This thesis has proposed the introduction of different therapeutic strategies based on nanoparticles to control inflammation and to interfere in the steps of recruitment leukocytes due to the association between chronic inflammation and various diseases and the impoatant role of leukocyte adhesion and subendothelial migration . The first part will present current issues on the use of nanoparticles for the development of targeted anti-inflammatory therapies. The original part of the paper is focused on (1) the development of therapeutic agents nanocarriers to achieve a targeted transport to activated vascular endothelium, the purpose beeing to interfere selectively with endothelial dysfunction or inhibit chemokine-receptor interaction and to prevent accumulation of pro-inflammatory cells in the vessel wall, and (2) the use of nanoparticles to modulate the monocytes / macrophages functions in order to reduce atherosclerotic plaque inflammation.

The first part of the thesis shows the current state of knowledge and is organized in two chapters.

Chapter 1 presents general concepts about inflammatory process. Penetration of pathogenic microorganisms or shel altered molecules, lead to onset of an acute inflammatory response characterized by infiltration of neutrophils in the first 6-24 hours and then are replaced by monocytes / macrophages. Proinflammatory agent is removed and reversible collateral tissue injury occurs, cellular debris removal by macrophages and restoration of tissue homeostasis with complete restoration of the original tissue architecture. If it is not properly induced an inflammatory response, the stimulus persists, there is infiltration of macrophages and lymphocytes that synthesize cytokines and chemokines and amplify the inflammatory response, causing irreversible tissue damage. It produces fibrosis - initial tissue is replaced by connective tissue. Chronic inflammation is involved in numerous pathologies such as atherosclerosis, chronic obstructive pulmonary disease, rheumatoid arthritis, multiple sclerosis, cancer, obesity, asthma, inflammatory bowel disease, and neurodegenerative diseases.

Chapter 2 presents some introductory concepts about nanotherapy in decreasing the inflammatory process. Many cells and mediators involved in inflammation, can be used as markers in the target or in the disease stage detection .

Patients presentation in late stages of the disease, the organisms failure to adapt at current therapy models, and improving the biological activity of pharmacological agents / drugs by encapsulation in nanoparticles led to the development of a new therapy and diagnostic strategies - nanoteragnostic that it assume both patient diagnosis and treatment.

Because unincorporated drugs can easily diffuse from /in blood vessel, leading to a decrease of the active substance in the affected area, was performed their encapsulation in the nanoparticles. If nanoparticles have left the blood vessel, they can not coming back because of their large size and has place a progressive accumulation in the affected area. coupling of peptides or antibodies to the nanocarriers surface, able to recognize molecules expressed by affected cells may lead to a targeted transport of active substances in the affected tissue.

In Part II - "Original Contributions" are presented the results of experiments aimed at controlling inflammation and able to interfere in the steps of leukocyte recruitment. The present work was centralized to achieve three major objectives:

I. targeted transport in activated vascular endothelium using nanocarriers for therapeutic agents to selectively interfere with endothelial dysfunction

II. development of a specific transport nanosistem compounds to activated endothelial cells to inhibit chemokine-receptor interaction, in order to prevent accumulation of proinflammatory cells in the vascular wall

III. using nanotechnology to modulate functions of monocytes / macrophages to reduce atherosclerotic plaque inflammation.

In Chapter I I presented targeted transport of therapeutic agents in nanocarriers to activated vascular endothelium. In inflammation, the endothelium plays an important role. Excessive and sustained exposure to pro-inflammatory mediators lead to endothelial dysfunction translated, in part, by expressing of cell surface adhesion molecules (eg E-and P-selectin, VCAM-1 and ICAM-1) that mediate leukocyte recruitment and adhesion to endothelium.

Induction or increased expression of specific molecules provides opportunities for the transport of selective therapeutic agents to an certain affected endothelial vascular segment.

To achieve a selective transport to activated endothelium they were used various nanosystems (liposomes, lipid nanoparticles) and was evaluated the targeting ability of nanocarriers to activated endothelium compared with normal endothelium, internalization efficiency of nanoparticles by endothelial cells, and therapeutic effects of compound incorporated into nanoparticles.

In this purpose, were performed studies in vitro, on cultured endothelial cells and also was followed targeted efficiency of vascular endothelium with liposomes using animal models using transgenic mice that develop atherosclerosis (ApoE-deficient mice). In vitro and in vivo results indicate a specific binding of liposomes directed to VCAM-1 and the liposomes obtained can be further used as carriers of drugs to endothelium covering atheromatous plaques.

Also, preliminary results show that AG490,free and encapsulated in nanoparticles contribute to decreasing of monocytes adhesion to activated endothelium by inhibiting Jak2/STAT3 pathway, and the effect of the inhibitor is increased by encapsulation in nanocarriers.

Chapter II is focused to obtein a specific transport nanosistem of therapeutic agents, able to destabilize and controlled release of compound encapsulated on the target cell surface. These nanocarriers could be efficient means of trasnsport that allow a controlled release of the chemokine receptor antagonists on the surface of the activated endothelial cells that block the chemokine / chemokine receptors interaction and prevent the transmigration of leukocytes into the subendothelial space.

Leukocyte infiltration is strongly regulated by chemokines. Chemokines are small polypeptides, highly specialized, which function as regulators of cell trafficking through interactions with G protein-coupled receptors on the surface of leukocytes. In our research we studied the effect of chemokine receptor antagonists on monocytes adhesion and infiltration through endothelial monolayer mimicking inflammatory conditions. Using Xcelligence system, I followed in real time: 1) endothelial cells monolayer formation, 2) the effect of proinflammatory cytokine TNF-α on endothelial cells, 3) adhesion and infiltration of monocytes and 4) the protective effect of chemokine receptor antagonists on the monolayer integrity. The data indicate that blocking the chemokine receptor CCR2 and CCR5 can significantly reduce transmigration through the endothelium, this being achieved through a decrease in the accumulation of monocytes in the blood vessel wall and reduce the inflammatory process. However, experimental and clinical testing of potential inhibitors of chemokines and their receptors for the treatment of inflammatory and immunological diseases have side effects. Local transport of chemokine receptors antagonists, in certain areas may be a better strategy to slow down or interrupt the inflammatory process. Design of transport vehicles to be able to "deliver" the drug at the affected site is a promising way to treat inflammation. Therefore, to obtain a therapeutic benefit by specific targeting of activated endothelial, we designed target-sensitive liposomes capable to release the compund

incapsulated-in after binding to target. They can be efficient transport vehicles for a controlled release of the chemokine receptor antagonists to activated endothelial surface capable to block chemokine / chemokine receptors interaction and to prevent transmigration of leukocytes into the subendothelial space.

In Chapter III I watched the modulation functions of monocytes / macrophages using nanotechnology in order to reduce atherosclerotic plaque inflammation.

Macrophages are essential in the inflammatory process that accompanies atherogenesis, from fatty streaks formation until to the processes leading to plaque rupture and acute coronary syndromes. One of the objectives was to follow the production of a recently discovered proinflammatory cytokine, resistin, by human monocytes as a result of their exposure to high glucose. We also investigated the mechanisms involved in the administration effect of clodronate liposomes (treatment leads to depletion of monocytes / macrophages) on the viability of vascular wall cells (endothelial cells - EC, smooth muscle cells - SMC), monocytes and macrophages. We studied the effects of apoptotic monocyte interaction with vascular wall cells and we looked at monocytes / macrophages adhesion to endothelial cells, smooth muscle cells and changes occurring in proliferation (PCNA) and intracellular signaling pathways (MAPKinazele: p38 and ERK) in smooth muscle cells.

The results show that: (1) significant levels of glucose induce resistin expression in human monocytic U937 (mRNA and protein), (2) p38, ERK1 / 2 and JNK MAPKinases and NF-kB transcription factor are involved in this mechanism, (3) insulin significantly reduced resistin expression induced by high glucose independent of signaling pathways MAPKinases: PI3K, ERK1 / 2 and p38.

Experiments designed to study the administration effects of clodronate liposomes on vascular wall cells and monocytes / macrophages show that small unilamellar liposomes are taken predilection by endothelial cells and smooth muscle cells, whereas multilamellar liposomes are internalized by human monocytes U937, murine macrophages Raw 264.7 and peritoneal macrophages isolated from mice. cell viability studies have shown that endothelial cells and smooth muscle cells viability is not significantly affected by MLV and SUV encapsulated clodronate, whereas, the biological activity of clodronate encapsulated in MLV on macrophages is higher than free clodronate with a significant decrease in their viability; the type of cell death induced is apoptosis.

Induction of apoptosis in monocytes determine changes in their interactions with vascular wall cells. Communication between apoptotic cells and smooth muscle cells causes a decrease in proliferation 35% and phosphorylation of p38 (~ 35%) and ERK (70%)

MAPkinases in smooth muscle cells. Also, the monocyte apoptosis was induced by clodronate liposomes show increased adhesion to blood wall cells compared with normal monocytes. Following the results obtained in different experimental models with inflammation and by using different types of nanotransport, we can draw the following conclusions: 1) liposomes directed to VCAM-1 are able to transport drugs to activated endothelial cells , 2) lipid nanoparticles can be used for intracellular transport in the endothelial cells of hydrophobic substances, 3) the nanosystem of target-sensitive transport developed can provide local therapeutic agents in the vicinity of activated endothelium and 4) the liposomes may be able to transport active substances to modulate the functions of monocytes / macrophages for reducing the inflammatory process.

Studies in this paper are the applicative nature, the ultimate goal being to control and reduce the inflammatory process using different therapeutic strategies based on nanocarriers.

Mots-clés: inflammation, inflammation aiguë, inflammation chronique, cytokines, chimiokines, des cellules endothéliales, les cellules musculaires lisses vasculaires humaines, monocytes / macrophages, des molécules d'adhérence cellulaire, souris déficientes en ApoE, adhérence, transmigration, nanothérapie, nanotransporteurs, nanoparticules lipidiques, liposomes, antagonistes des récepteurs de chimiokines, résistine, MAP kinases, clodronate, apoptose.

L'inflammation est un mécanisme du système immunitaire inné dans le cadre d'une réponse biologique complexe de tissus vasculaires aux stimuli nuisibles (pathogènes, les cellules endommagées, des irritants). Le résultat final du processus inflammatoire est de protéger l'organisme contre l'infection et la restauration structurelle et fonctionnelle des tissus endommagés. Selon la gravité de la réaction peut être une inflammation aiguë, entraînant l'élimination des stimuli inflammatoires et la récupération des tissus dans les conditions physiologiques, ou peut être un processus inflammatoire chronique conduisant à l'exagération et l'apparition de diverses pathologies. L'inflammation chronique est impliquée dans de nombreuses pathologies, notamment l'athérosclérose, le cancer, l'arthrite rhumatoïde, la sclérose en plaques, la maladie intestinale inflammatoire, la maladie d'Alzheimer, le lupus, les allergies, etc.

Un rôle important dans le processus inflammatoire revient a l'activation de l'endothélium. Dans des conditions normales, l'endothélium vasculaire est non thrombogène et non adhérente. Les changements dans micro-environnement affecte les cellules endothéliales qui expriment molécules d'adhésion (VCAM-1, ICAM-1, E et la sélectine P, fractalkine), qui en se liant aux récepteurs correspondants sur la surface des leucocytes et des plaquettes, conduisent à leur recrutement et leur adhésion à l'endothélium. En plus de molécules d'adhésion, les cellules endothéliales expriment de chimiokines telles que la MCP-1 (CCL2), RANTES (CCL5), fractalkine (CX3CL1) qui se lient à des récepteurs homologues sur la surface des leucocytes et ensemble aux les molécules d'adhérence contribuent à leur adhérence et au transmigration. Les chimiokines se lient aux glycosaminoglycanes présents sur la membrane des cellules endothéliales et guident l'entrée des leucocytes dans la paroi artérielle. Les monocytes sont attirés par des chimiokines CCL2, CCL5 et CX3CL1 qui activent les récepteurs CCR2, CCR5 et CX3CR1 sur les monocytes.

En raison de l'implication des molécules d'adhésion cellulaire et des chimiokines dans le développement des maladies inflammatoires chroniques , l'intervention thérapeutique ouvre de nouvelles perspectives dans la prévention et le traitement de ces maladies.

Manipulation functionelle du système des chimiokines , comme inhiber de l'interaction chimiokines / récepteurs des chimiokines, en utilisant des antagonistes des chimiokines (AC) ou des antagonistes des récepteurs de chimiokines (ARC) pourrait être une option thérapeutique importante pour éviter l'accumulation de cellules inflammatoires et l'aggravation de la maladie (athérogenèse, métastases). Une approche de moduler le ciblage d'un médicament à un site spécifique est de concevoir des véhicules de transport pour être en mesure de «livrer» le médicament au site actif affecté. Le façon plus prometteur pour cibler des nanotransporteurs aux sites spécifiques est la fixation du ligands sur leur surface qui peut transporter la substance active dans la cellule ou de reconnaître des molécules cibles spécifiques.

Compte tenu de l'association de l'inflammation chronique à diverses maladies et le rôle joué de l'adhérence des leucocytes à l'endothélium et la migration endothéliale, cette thèse a proposé l'introduction de différentes stratégies thérapeutiques en fonction des nanoparticules pour contrôler l'inflammation et de s'ingérer dans les étapes de recrutement globules blancs. La première partie présente les enjeux actuels sur l'utilisation de nanoparticules pour le développement de thérapies anti-inflammatoires ciblées. La partie originale de l'article se concentre sur (1) le développement de transporteurs d'agents thérapeutiques par parvenir un transport cible a l'endothélium activé afin d'interférer sélectivement avec dysfonction endothéliale ou inhiber l'interaction chimiokine-récepteur afin d'éviter l'accumulation de cellules pro-inflammatoires dans paroi vasculaire et (2) l'utilisation des nanoparticules pour moduler les fonctions des monocytes / macrophages afin de réduire l'inflammation de la plaque athéroscléreuse.

La première partie de la thèse montre l'état actuel des connaissances et est organisé en deux sections.

La première section présente les notions générales sur le processus inflammatoire. La pénétration des micro-organismes pathogènes ou des molécules propres modifiées , provoque le déclenchement d'une réponse inflammatoire aiguë caractérisée par une infiltration de neutrophiles dans les premiers 6-24 heures, et apres leur remplacément par des monocytes / macrophages. Survient l'elimonation de l'agent pro-inflammatoire avec lésion réversible de le tissus de collatéral, enlèvement des debris cellulaire par les macrophages et la restauration de l'homéostasie avec restauration complète de l'architecture initiale du tissu. Si une réponse inflammatoire n'est pas correctement induit, le stimulus persiste, il y a infiltration des macrophages et des lymphocytes qui synthétisent des cytokines et de chimiokines qui amplifient la réponse inflammatoire, provoquant des lésions irréversibles des tissus. Elle

produit une fibrose - tissu initial est remplacé de tissus conjonctif. L'inflammation chronique est impliquée dans de nombreuses pathologies telles que l'athérosclérose, la bronchopneumopathie chronique obstructive, la polyarthrite rhumatoïde, la sclérose en plaques, le cancer, l'obésité, l'asthme, les maladie intestinale inflammatoire, et les maladies neurodégénératives.

La section 2 présente quelques concepts préliminaires sur l'utilisation nanothérapie à réduire le processus inflammatoire. De nombreuses cellules et les médiateurs de l'inflammation, peuvent être utilisés comme marqueurs de la cible ou à l'étape de détection de la maladie.

Présentation des patients à un stade avancé de la maladie, l'incapacité des organismes à répondre à des modèles de thérapie en cours, et l'amélioration de l'encapsulation de l'activité biologique d'agents pharmacologiques / médicaments dans des nanoparticules a conduit au développement d'une nouvelle thérapie et les stratégies de diagnostic - nanoteragnostic qui supposent au meme temps le diagnostic et le traitement du patient.

Parce que les médicaments peuvent facilement diffuser à l'extérieur ou en le vaisseau sanguin, conduisant à une diminution de la substance active dans la zone touchée a été adoptée à l'encapsulation des nanoparticules que une fois qu'ils ont quitté le vaisseau sanguin ne reviendront pas en raison de leur grande taille conduisant à leurs accumulation progressive dans la zone touchée. Ajoutant de peptides des nanotransporteurs ou de anticorps sur la surface, capable de reconnaître des molécules exprimées par les cellules affectées peut conduire à un transport dirigé de substances actives dans les tissus touchés.

Dans la Partie II - "contributions originales" sont présentés les résultats d'expériences visant à contrôler l'inflammation et capable d'intervenir dans les étapes de recrutement des leucocytes. Le présent travail était centralisé à atteindre trois grands objectifs:

I. le transport ciblé dans endothélium vasculaire activé utilisant nanotransporteurs d' agents thérapeutiques pour interférer sélectivement avec dysfonction endothéliale,

II. le développement d'un nanosistem de transport spécifiques des composés aux cellules endothéliales activées pour inhiber l'interaction chimiokine-récepteur, afin d'éviter l'accumulation de cellules pro-inflammatoires dans la paroi vasculaire

III. utiliser la nanotechnologie de moduler les fonctions des monocytes / macrophages pour réduire l'inflammation de la plaque d'athérome.

Dans le chapitre I, nous avons présenté le transport ciblé de nanotransporteurs d'agents thérapeutiques à l'endothélium vasculaire activé. Dans l'inflammation, l'endothélium joue un rôle important. Une exposition excessive et prolongée à des médiateurs pro-

inflammatoires conduisent à la dysfonction endothéliale qui se traduit, en partie, par l'expression des molécules d'adhésion à la surface cellulaire (par exemple, E et P-sélectine, VCAM-1 et ICAM-1) qui interviennent dans le recrutement et l'adhésion des leucocytes à l'endothélium. Induction ou augmentation de l'expression de molécules spécifiques offre des possibilités pour le transport sélective d'agents thérapeutiques à l'endothélium affectée d'un segment vasculaire. Pour obtenir un transport sélectif à l'endothélium activé ont été utilisés différents nanosystèmes de transporter (liposomes, nanoparticules lipidiques) et d'évaluer le capacité de ciblage du nanotransporteurs à l'endothélium activé par rapport à l'endothélium normal, l'efficace de l'internalisation de nanoparticules par les cellules endothéliales, et des effets thérapeutiques des composés incorporés dans des nanoparticules. À cette fin, des études in vitro ont été réalisées dans les cellules endothéliales en culture et a été également suivre l'efficacité du ciblage des endothéliales vasculaires avec liposomes utilisant des modèles animaux de souris transgéniques qui développent l'athérosclérose (souris déficientes en ApoE). Les résultats in vitro et in vivo indiquent une liaison spécifique de liposomes destinés à VCAM-1 et que les liposomes obtenus peuvent ensuite être utilisées comme vecteurs de médicaments à l'endothélium couvrant plaques d'athérome.

En outre, les résultats préliminaires indiquent que AG490, à la fois encapsulé dans les nanoparticules de transporteur et libre contribuent à réduire l'adhérence des monocytes à l'endothélium activé par inhibition du chemin Jak2/STAT3 et l'effet de l'inhibiteur est augmenté par encapsulation dans nanovehicule.

Le chapitre II est axé sur l'obtention d'un nanosystème pour le transport spécifique d'agents thérapeutiques, capable de déstabiliser et de libérer contrôlée le composé encapsulé sur la surface de la cellule cible. Ces moyens de nanotransporteurs peuvent être transport efficace pour une libération contrôlée des antagonistes des récepteurs de chimiokines qui bloquent l'interaction chimiokine / chimiokine récepteurs de surface endothéliales activées et donc entraver la transmigration des leucocytes dans l'espace sous-endothélial.

Infiltration leucocytaire est fortement réglementée par les chimiokines. Les chimiokines sont des petits polypeptides, très spécialisés qui fonctionnent comme des régulateurs du trafic cellulaire à travers des interactions faites par G récepteurs couplés aux protéines à la surface des leucocytes. Dans notre recherche, nous avons étudié l'effet des antagonistes des récepteurs de chimiokines sur l'adhérence et l'infiltration des monocytes à travers monocouche endothéliale imitant conditions inflammatoires. En utilisant le système de xCELLigence, j'ai regardé en temps réel: 1) monocouche formant des cellules endothéliales, 2) l'effet dela cytokine pro-inflammatoire TNF-α sur les cellules endothéliales,

3) adhérence et l'infiltration des monocytes et 4) l'effet protecteur des antagonistes des récepteurs de chimiokines sur l'intégrité monocouche. Les données indiquent que le blocage des récepteurs des chimiokines CCR2 et CCR5 permet de réduire considérablement la transmigration travers l'endothélium, ceci étant réalisé grâce à une diminution de l'accumulation de monocytes dans la paroi du vaisseau sanguin et à réduire les processus inflammatoires. Cependant, les essais expérimentales et cliniques des inhibiteurs potentiels de chimiokines et leurs récepteurs pour le traitement des maladies inflammatoires,ont révélé des effets immunologiques latérale. Transport local de antagonistes des récepteurs de chimiokines dans certaines zones pourraient être une meilleure stratégie pour ralentir ou interrompre le processus inflammatoire. Conception des véhicules de transport pour être en mesure de «livrer» le médicament au site actif affecté est un moyen prometteur pour traiter l'inflammation. Ainsi, pour obtenir un bénéfice thérapeutique en ciblant l'activité endothéliale spécifique, nous avons conçu des liposomes cibles sensibles capables de libérer le composé encapsulé après la liaison au cible. Ils peuvent être transport efficace pour une libération contrôlée des antagonistes des récepteurs de chimiokines aux surface des endothéliales activées qui bloquent l'interaction chimiokine / chimiokine récepteurs et empêchent la transmigration des leucocytes dans l'espace sous-endothélial.

Dans le chapitre III, nous avons regardé fonctions de modulation de monocytes / macrophages en utilisant la nanotechnologie afin de réduire l'inflammation de la plaque d'athérome.

Les macrophages sont essentiels dans le processus inflammatoire qui accompagne l'athérogenèse, de la formation de stries de lipide aux processus à la rupture de plaque et les syndromes coronariens aigus. L'un des objectifs était de suivre la production d'une cytokine pro-inflammatoire récemment découvert, la résistine, par des monocytes humains en raison de leur exposition à la glucose élevé. Nous avons également étudié les mécanismes impliqués dans l'effet de l'administration de liposomes de clodronate (traitement conduit à l'épuisement des monocytes / macrophages) sur la viabilité des cellules paroi vasculaire (cellules endothéliales - CE, cellules musculaires lisses - CML) et les monocytes et les macrophages. Nous avons étudié les effets de l'interaction monocytes apoptotique des cellules de la paroi vasculaire en consultant d'adhésion des monocytes / macrophages aux cellules endothéliales, cellules musculaires lisses et des changements survenus dans la prolifération (PCNA) et les voies de signalisation intracellulaires (MAPKinazele: p38 et ERK) dans cellules musculaires lisses. Les résultats montrent que: (1) des niveaux élevés de glucose induisent expression de la résistine chez monocytes l'homme U937 (ARNm et protéine), (2) MAPKinazele p38 ERK1

/ 2 et JNK et NF-kB facteur de transcription impliqué dans cette mécanisme, (3) l'insuline significativement réduit expression de la résistine induit par l'hyperglycémie indépendant de voies de signalisation MAP-kinase PI3K, ERK1 / 2 et p38.

Les expériences réalisées pour étudier les effets de l'administration de liposomes de clodronate sur les cellules de la paroi vasculaire et les monocytes / macrophages montrent que les petits liposomes unilamellaires sont prises prédilection par les cellules endothéliales et musculaires lisses, alors que des liposomes multilamellaires sont internalisées par les monocytes humains U937, les macrophages murins Raw 264.7 et les macrophages péritonéale isolées de souris. Études de faisabilité énumérés ci-dessus types de cellules ont montré que la viabilité des cellules endothéliales et musculaires lisses n'est pas significativement affectée par MLV et SUV encapsulé clodronate, alors que, en macrophages, l'activité biologique des clodronate encapsulé dans MLV est plus élevé que le clodronate libre avec une diminution significative de leur viabilité, le type de mort cellulaire induite par l'apoptose.

L'induction de l'apoptose dans les monocytes provoque des changements dans leurs interactions avec les cellules de la paroi vasculaire. La communication entre les cellules apoptotiques et les cellules musculaires lisses entraîne une diminution de la prolifération de 35% et de la phosphorylation MAP-Kinases p38 (~ 35%) et ERK (70%) dans les cellules musculaires. En outre, les monocytes a été induite l'apoptose par les liposomes de clodronate montrer une adhérence accrue de cellules de la paroi vasculaire par rapport à monocytes normaux.

Voici les résultats obtenus dans différents modèles expérimentaux pour induire l'inflammation et en utilisant différents types de nanotransporteurs, nous pouvons tirer les conclusions suivantes: 1) liposomes destinés à VCAM-1 sont capables de transporter médicaments à des cellules endothéliales activées, 2) nanoparticules lipidiques peut être utilisé pour le transport intracellulaire dans les cellules endothéliales des substances hydrophobes, 3) nanosystèmes de transport cible sensible développé peut fournir des agents thérapeutiques locales au voisinage de l'endothélium activé et 4) les liposomes peut être capable de transporter des substances actives pour moduler les fonctions des monocytes / macrophages dans réduire le processus inflammatoire.

Les études dans ce papier sont appliquées nature, le but ultime étant de contrôler et de réduire le processus inflammatoire en utilisant différentes stratégies thérapeutiques basées sur nanotransporteurs.

Cuvinte cheie: inflamatia, inflamatie acuta, inflamatie cronica, citokine, chemokine, celule endoteliale, celule musculare netede vasculare umane, monocite/macrofage, molecule de adeziune celulara, soareci apoE-deficienti, adeziune, transmigrare, nanoterapie, nanocarausi, nanoparticule lipidice, liposomi, antagonisti de receptori chemokinici, rezistina, MAPKinaze, clodronat, apoptoza.

Inflamatia este un mecanism al sistemului imun innascut facand parte dintr-un raspuns biologic complex al tesutului vascular la stimuli nocivi (patogeni, celule deteriorate, iritanti). Rezultatul final al procesului inflamator este de a proteja organismul de raspandirea unor infectii si restaurarea structurala si functionala a tesuturilor afectate. In functie de severitatea reactiei, inflamatia poate fi acuta, determinand in final eliminarea stimulilor inflamatori si revenirea tesutului la conditiile fiziologice, sau poate fi cronica ducand la exagerarea procesului inflamator si aparitia a diferite patologii. Inflamatia cronica este implicata in numeroase patologii printre care: ateroscleroza, cancer, artrita reumatoida, scleroza multipla, bolile intestinale inflamatorii, Alzheimer, lupus eritematos sistemic, alergii, etc.

Un rol important in procesul inflamator il are activarea endoteliului. In conditii normale, endoteliul vascular este non-trombogenic si non-aderent. Schimbari in micromediul inconjurator afecteaza celulele endoteliale care vor exprima molecule de adeziune (VCAM-1, ICAM-1, E- si P-selectina, fractalkina), care prin legare la receptorii corespunzatori de pe suprafata leucocitelor si plachetelor conduc la recrutarea si aderarea acestora la endoteliu. Pe langa moleculele de adeziune, celulele endoteliale exprima si chemokine precum MCP-1 (CCL2), RANTES (CCL5), fractalkina (CX3CL1) care se leaga la receptori omologi de pe suprafata leucocitelor si impreuna cu moleculele de adeziune contribuie la adeziunea si transmigrarea acestora. Chemokinele se leaga la glicozaminoglicanii prezenti pe membrana celulelor endoteliale si ghideaza intrarea leucocitelor in peretele arterial. Monocitele sunt

atrase de chemokinele CCL2, CCL5 şi CX3CL1 care activeaza receptorii CCR2, CCR5 şi CX3CR1 de pe monocite.

Datorita implicarii moleculelor de adeziune celulara si a chemokinelor in dezvoltarea bolilor cronice inflamatorii, interventia terapeutica deschide noi oportunitati pentru prevenirea si tratamentul acestor boli. Manipularea functionala a sistemului de chemokine, cum ar fi inhibarea interactiei chemokine/receptori chemokinici, prin utilizarea de antagonisti chemokinici (CA) sau antagonisti de receptori chemokinici (CRA) ar putea constitui o optiune terapeutica importanta pentru prevenirea acumularii de celule inflamatorii si agravarea unor boli (aterogeneza, metastazare). Un mod de abordare pentru a modula directionarea unui medicament catre un situs specific este de a concepe vehicule de transport care sa fie capabile sa "livreze" medicamentul la situsul afectat. Calea cea mai promitatoare pentru directionarea unor nanotransportori la situsuri specifice o reprezinta atasarea pe suprafata lor a unor liganzi care sa poata transporta substanta activa in celula sau sa recunoasca molecule tinta specifice.

Dat fiind asocierea inflamatiei cronice cu diverse boli si rolul jucat de adeziunea leucocitelor la endoteliu si migrarea subendoteliala, aceasta teza de doctorat si-a propus introducerea de diferite strategii terapeutice bazate pe nanoparticule cu scopul de a controla inflamatia si de a interfera in pasii de recrutare ai leucocitelor. In prima parte vor fi prezentate aspecte actuale cu privire la utilizarea nanoparticulelor pentru realizarea unor terapii directionate anti-inflamatorii. Partea originala a lucrarii se concentreaza pe (1) dezvoltarea unor nanotransportori de agenti terapeutici pentru realizarea unui transport tintit la endoteliul vascular activat cu scopul de a interfera selectiv cu disfunctia endoteliala sau de a inhiba interactiunea chemokine-receptori, pentru a preveni acumularea celulelor proinflamatorii in peretele vascular si (2) pe utilizarea nanoparticulelor pentru modularea functiilor monocitelor/macrofagelor cu scopul de a reduce inflamatia placii aterosclerotice.

Prima parte a tezei prezinta stadiul actual al cunostintelor si este organizata in 2 capitole.

Capitolul 1 prezinta notiuni generale despre procesul inflamator. Patrunderea de patogeni proveniti de la microorganisme sau molecule proprii alterate, determina declansarea unui raspuns inflamator acut caracterizat de infiltrarea de neutrofile in primele 6-24 de ore, dupa care, sunt inlocuite de monocite/macrofage. Are loc indepartarea agentului pro-inflamator cu vatamarea reversibila a tesutului colateral, indepartarea debriurilor celulare de catre macrofage si restaurarea homeostaziei tisulare cu refacerea completa a arhitecturii

tesutului initial. In cazul in care, nu este indus un raspuns inflamator corespunzator, stimulul persista, are loc infiltrarea de macrofage si limfocite care sintetizeaza citokine si chemokine ce amplifica raspunsul inflamator, determinand distrugeri tisulare ireversibile. Se produce fibrozarea – inlocuirea tesutului initial cu tesut conjunctiv. Inflamatia cronica este implicata in numeroase patologii precum: ateroscleroza, bolile pulmonare obstructive cronice, artrita reumatoida, scleroza multipla, cancer, obezitate, astm, boli intestinale inflamatorii, dar si boli neurodegenerative.

Capitolul 2 prezinta cateva notiuni introductive despre utilizarea nanoterapiei in reducerea procesului inflamator. Numeroase celule si mediatori, implicati in inflamatie, pot fi folositi ca markeri fie in tintire, fie in detectarea stadiului bolii.

Prezentarea pacientilor in stadiile tarzii ale bolii, incapacitatea unor organisme de a raspunde la modelele de terapie actuala, dar si imbunatatirea activitatii biologice prin incapsularea unor agenti farmacologici/medicamente in nanoparticule au condus la dezvoltarea unei noi strategii de terapie si diagnosticare – nanoteragnostic, care isi presupune atat diagnosticarea cat si tratarea pacientului.

Deoarece medicamentele neincorporate pot difuza usor din/in vasul de sange, conducand la o scadere a substantei active la locul afectat, s-a trecut la incapsularea lui in nanoparticule care, odata ce au parasit vasul sangvin nu se mai intorc datorita dimensiunii lor mari avand loc o acumulare progresiva la locul afectat. Adaugarea de peptide sau anticorpi la suprafata nanocarausilor, capabili sa recunoasca molecule exprimate de celulele afectate poate conduce la un transport directionat de substante active, in tesutul afectat.

In Partea a II a - "Contribuţ ii originale", sunt prezentate rezultatele obtinute din experimentele care au avut ca scop controlarea inflamatiei si posibilitatea de a interfera in pasii de recrutare ai leucocitelor. Astfel, lucrarea de fata s-a centralizat pe indeplinirea a trei mari obiective principale:

I. transportul tintit la endoteliul vascular activat utilizand nanotransportori de agenti terapeutici pentru a interfera selectiv cu disfunctia endoteliala,

II. dezvoltarea unui nanosistem pentru transportul specific de compusi la suprafata celulelor endoteliale activate in vederea inhibarii interactiunii chemokine-receptori, cu scopul de a preveni acumularea celulelor proinflamatorii in peretele vascular

III. utilizarea nanotehnologiei pentru modularea functiilor monocitelor/macrofagelor pentru a reduce inflamatia placii aterosclerotice.

In capitolul I am prezentat transportul tintit de nanocarausi cu agenti terapeutici catre endoteliul vascular activat. In inflamatie, endoteliul joaca un rol important. Expunerea excesiva si sustinuta la mediatori pro-inflamatori conduce la disfunctia endoteliala care se traduce, in parte, prin exprimarea pe suprafata a moleculelor de adeziune celulara (ex: E- si P- selectina, VCAM-1 si ICAM-1) care mediaza recrutarea si adeziunea leucocitelor la endoteliu. Inducerea sau exprimarea crescuta de molecule specifice ofera oportunitati pentru transportul selectiv de agenti terapeutici la endoteliul afectat dintr-un anumit segment vascular. Pentru realizarea unui transport selectiv la endoteliul vascular activat, au fost folosite diferite nanosisteme de transport (liposomi, nanoparticule lipidice) si s-a evaluat capacitatea de tintire a nanotransportorilor la endoteliul vascular activat comparativ cu endoteliul normal, eficienta de internalizare a nanoparticulelor de catre celulele endoteliale, precum si efectele terapeutice ale compusului incorporat in nanoparticule. In acest scop, s-au realizat studii in vitro pe culturi de celule endoteliale si de asemenea a fost urmarita eficienta de tintire a endoteliului vascular cu ajutorul liposomilor folosind modele animale de soareci transgenici care dezvolta ateroscleroza (soareci ApoE-deficienti). Rezultatele obtinute atat in vitro cat si in vivo indica o legare specifica a liposomilor directionati catre VCAM-1 si faptul ca liposomii obtinuti pot fi folositi in continuare ca transportori de medicamente la endoteliul ce acopera placa ateromatoasa.

De asemenea, rezultatele preliminare arata faptul ca AG490, atat incapsulat in nanoparticule transportoare cat si liber, contribuie la scaderea adeziunii monocitelor la endoteliul activat prin inhibarea caii Jak2/STAT3, iar efectul inhibitorului este crescut prin incapsularea in nanovehicule.

Capitolul al II-lea este axat pe obtinerea unui nanosistem pentru transportul specific de agenti terapeutici, capabil sa se destabilizeze si sa elibereze controlat compusul incorporat, la suprafata celulei tinta. Acesti nanotransportori pot constitui vehicule de transport eficiente pentru o eliberare controlata de antagonisti de receptori chemokinici la suprafata endoteliului activat care sa blocheze interactia chemokine/receptori chemokinici si sa impiedice astfel, transmigrarea leucocitelor in spatiul subendotelial.

Infiltrarea leucocitelor este puternic reglata de chemokine. Chemokinele sunt polipeptide mici, inalt specializate, care functioneaza ca reglatori ai traficului celular prin interactiunile realizate cu receptorii cuplati cu proteina G de pe suprafata leucocitelor. In cercetarile noastre am studiat efectul unor antagonisti de receptori chemokinici asupra adeziunii si infiltrarii monocitelor prin monostratul de celule endoteliale mimand conditiile

inflamatorii. Utilizand sistemul Xcelligence, am urmarit in timp real: 1) formarea monostratului de celule endoteliale; 2) efectul citokinei pro-inflamatorii TNF-α asupra celulelor endoteliale; 3) adeziunea si infiltrarea monocitelor si 4) efectul protector al antagonistilor de receptori chemokinici asupra integritatii monostratului. Datele indica faptul ca, blocarea receptorilor chemokinici CCR2 si CCR5 poate reduce semnificativ transmigrarea prin endoteliu, aceasta realizandu-se printr-o descrestere a acumularii monocitelor in peretele vasului sangvin si reducerea procesului inflamator. Insa, testarea experimentala si clinica a unor potentiali inhibitori de chemokine si ai receptorilor lor pentru tratamentul bolilor inflamatorii, au evidentiat efecte imunologice secundare. Transportul local de antagonisti de receptori chemokinici in anumite zone poate constitui o strategie mai buna pentru a incetini sau intrerupe procesul inflamator. Conceperea de vehicule de transport care sa fie capabile sa "livreze" medicamentul la situsul afectat este o cale promitatoare in tratarea inflamatiei. Astfel, pentru a obtine un beneficiu terapeutic prin tintirea specifica a endoteliului activat, am conceput liposomi tinta senzitivi capabili sa elibereze compusul incorporat dupa legarea la tinta. Acestia pot constitui vehicule de transport eficiente pentru o eliberare controlata de antagonisti de receptori chemokinici la suprafata endoteliului activat care sa blocheze interactia chemokine/receptori chemokinici si sa impiedice transmigrarea leucocitelor in spatiul subendotelial.

In capitolul al III-lea am urmarit modularea functiilor monocitelor/macrofagelor folosind nanotehnologia, cu scopul de a reduce inflamatia placii aterosclerotice.

Macrofagele sunt esentiale in procesul inflamator care insoteste aterogeneza, incepand de la formarea striurilor lipidice pana la procesele ce duc la ruptura placii si la sindroame coronariene acute. Unul din obiective a fost sa urmarim productia unei citokine proinflamatoare recent descoperita, rezistina, de catre monocitele umane ca urmare a expunerii lor la concentratii crescute de glucoza. De asemenea, am investigat mecanismele implicate in efectul administrarii de liposomi cu clodronat (tratament ce conduce la depletia monocitelor/macrofagelor) asupra viabilitatii celulelor peretelui vascular (celulele endoteliale-CE si celulele musculare netede-CMN) si a monocitelor si macrofagelor. Am studiat efectele interactiunii monocitelor apoptotice cu celulele peretelui vascular uitandu-ne la adeziunea monocitelor/macrofagelor la celulele endoteliale, celulele musculare netede, precum si modificarile ce apar in proliferare (PCNA) si in caile de semnalizare intracelulara (MAPKinazele: p38 si ERK) din celulele musculare netede.

Rezultatele obtinute arata faptul ca: (1) concentratia crescuta de glucoza induce semnificativ exprimarea rezistinei in monocitele umane U937 (ARNm si proteina); (2) MAPKinazele p38, ERK1/2 si JNK precum si factorul de transcriptie NF-kB sunt implicati in acest mecanism; (3) insulina reduce semnificativ expresia de rezistina indusa de glucoza crescuta, independent de caile de semnalizare MAPKinazice PI3K, ERK1/2 sau p38.

Experimentele realizate pentru studiul efectelor administrarii de liposomi cu clodronat asupra celulelor peretelui vascular si a monocitelor/macrofagelor arata faptul ca liposomii unilamelari mici sunt preluati in special de catre celulele endoteliale si musculare netede, pe cand liposomii multilamelari sunt internalizati de catre monocitele umane U937, macrofagele murine Raw 264.7 si macrofage peritoneale izolate de la soareci. Studiile de viabilitate pe tipurile celulare enumerate mai sus au aratat ca viabilitatea celulelor endoteliale si musculare netede nu este afectata semnificativ de MLV si SUV cu clodronat incapsulat, pe cand, in cazul macrofagelor activitatea biologica a clodronatului incapsulat in MLV este mai mare comparativ cu clodronatul liber avand loc o scadere semnificativa a viabilitatii lor, tipul de moarte celulara indusa fiind apoptoza.

Inducerea apoptozei in monocite determina schimbari in interactiunile lor cu celulele peretelui vascular. Comunicarea dintre celulele apoptotice si celulele musculare netede determina o scadere a proliferarii cu 35% si a fosforilarii MAPKinazelor p 38 (~35%) si ERK (70%) in celulele musculare. De asemenea, monocitele in care a fost indusa apoptoza cu ajutorul liposomilor cu clodronat manifesta o adeziune crescuta la celulele peretelui sangvin in comparatie cu monocitele normale.

In urma rezultatelor obtinute pe diverse modele experimentale in care s-a indus inflamatia si folosindu-se diferite tipuri de nanotransportori, se pot trage urmatoarele concluzii generale: 1) liposomii directionati catre VCAM-1 sunt capabili sa transporte medicamente la CE activate, 2) nanoparticulele lipidice pot fi folosite pentru transportul intracelular in celule endoteliale a substantelor hidrofobe, 3) nanosistemul de transport tinta senzitiv dezvoltat poate furniza local agenti terapeutici, in vecinatatea endoteliului vascular activat si 4) liposomii pot fi capabili sa transporte substante active pentru modularea functiilor monocitelor /macrofagelor in scopul reducerii procesului inflamator.

Studiile efectuate in acesta lucrare sunt de natura aplicativa, scopul final fiind acela de a controla si reduce procesul inflamator utilizand diferite strategii terapeutice bazate pe nanotransportori.

COMUNICAT DE PRESĂ

„PNRR: Fonduri pentru România modernă și reformată!”

Finalizarea proiectului STROMA: *Consolidarea competenței românești în cercetarea sindromului metabolic prin explorarea rolului apolipoproteinei A2 în dislipidemie, obezitate și diabet zaharat de tip II*

Institutul de Biologie și Patologie Celulară „Nicolae Simionescu” a finalizat cu succes proiectul ***„Consolidarea competenței românești în cercetarea sindromului metabolic prin explorarea rolului apolipoproteinei A2 în dislipidemie, obezitate și diabet zaharat de tip II” acronim STROMA***, cod proiect PNRR-III-C9-2022-I8-258, contract nr. 760060/23.05.2023, finanțat prin Planul Național de Redresare și Reziliență al României.

Proiectul a fost implementat în perioada 1 iulie 2023 – 30 iunie 2026, la sediul Institutului de Biologie și Patologie Celulară „Nicolae Simionescu” din București, de către membrii laboratorului de Reglare Genică și Terapii Moleculare sub coordonarea Dr. Kyriakos E. Kypreos.

Valoarea totală a proiectului a fost de 7.000.000 lei (7.606.842,14 lei cu TVA).

Proiectul STROMA a fost lansat pentru a determina exact cum o anumită proteină din sânge, numită apolipoproteina A2, influențează modul în care organismul nostru gestionează grăsimile și glucoza atunci când ne confruntăm cu o boală. Proiectul a examinat modul în care această proteină modifică traiectoria grăsimilor prin fluxul sanguin și cum alterează compoziția și eficacitatea HDL, care este colesterolul nostru „bun”. În același timp, cercetătorii au analizat modul în care proteina influențează capacitatea organismului nostru de a menține nivelurile de glucoză din sânge stabile și cum modifică modul în care grăsimea corporală stochează și arde energia. În cele din urmă, cercetătorii au integrat rezultatele pentru a înțelege modul în care această proteină influențează colesterolul, greutatea și diabetul. Dincolo de obiectivele științifice imediate, proiectul a reușit să pună bazele solide pentru o linie de cercetare nouă și durabilă pentru anii următori. Prin introducerea unor metodologii avansate și extinderea expertizei instituționale, STROMA a consolidat semnificativ potențialul de cercetare pe termen lung și capacitatea competitivă a institutului beneficiar în domeniul cercetării cardiovasculare.

Pe baza cunoștințelor dobândite, STROMA avansează semnificativ cercetarea translațională în domeniul bolilor metabolice și stabilește o bază științifică riguroasă pentru dezvoltarea de strategii terapeutice inovatoare care vizează bolile cardiovasculare.

REZUMATUL TEZEI DE DOCTORAT

Hormonii sunt definiți ca fiind substanțe chimice elaborate de o celulă sau grup de celule specializate (numite celule endocrine) și care sunt transportate prin sistemul circulator la o celulă țintă care răspunde printr-o modificare a funcției sale.[1]

Estrogenii sau Oestrogenii, sunt un grup de compuși din clasa hormonilor steroidici ce și-au primit denumirea în funcție de importanța lor atât în ciclul menstrual cât și în ciclul reproductiv. În organismul uman, estrogenii se găsesc sub trei forme: estradiol (produși de către ovare), estrone (produși în timpul menopauzei) și estriol (produși de către placentă).

În afara de protecția ce o oferă sistemului reproducător, hormonii estrogeni sunt cunoscuți a fi benefici și pentru alte organe și țesuturi. Efectele benefice ale estrogenilor s-au observat în creier (oferă neuroprotecție în cazul bolii Alzheimer), în ficat (reglarea colesterolului și a lipoproteinelor), la oase (previne apariția osteoporozei), în piele (combate îmbătrânirea) și poate reduce riscul cancerului de colon. [2,3]

De asemenea, s-a demonstrat că, estrogenii exercită efecte protectoare și asupra sistemului cardiovascular, asupra procesului de ischemie/reperfuzie, asupra țesutului cardiac lezat în urma unui infarct miocardic.[4,5]

Corpul uman produce trei forme de hormoni estrogeni, și anume estradiol (E2, $C_{18}H_{24}O_2$), estronă (E1, $C_{18}H_{22}O_2$) și estriol (E3, $C_{18}H_{24}O_3$). Cea mai studiată formă dintre cele 3 menționate anterior, este 17-beta estradiolul (E2), fiind și principalul contributor la activitatea estrogenică a femeilor aflate în perioada de pre-menopauză.

Pentru a-și exercita funcțiile biologice, hormonii estrogeni se leagă la situsuri de recunoaștere specifice numite **receptori.** Existența unui receptor estrogenic a fost demonstrată de Elwood Jensen în 1958, iar gena corespunzătoare a fost clonată tocmai în anul 1985.[6]

Mortalitatea cauzată de bolile cardiovasculare este rară în cazul femeilor aflate în pre-menopauză. Bărbații cu vârstă similară în comparație cu femeile aflate la pre-menopauză, prezintă un risc mai mare de a dezvolta hipertensiune arterială, precum și alte afecțiuni cardiovasculare (exemplu: boala arterială coronariană), însă, în cazul femeilor situația este diferită atunci când se instalează menopauza sau deja se afla la post-menopauză.

Mai multe studii observaționale și unele studii clinice efectuate la femei aflate la post-menopauză susțin ipoteza cu privire la E2 că este hormonul sexual ce acționează ca un "protector" al sistemului cardiovascular și circulator.[7,8]

Pe de altă parte, progrese continue se înregistrează în terapiile destinate regenerării țesuturilor ce folosesc celule stem pluripotente adulte/precursoare pentru a reconstrui sau regenera diferite țesuturi.

Domeniul celulelor stem mezenchimale (MSCs) a înregistrat progrese considerabile în ultimul deceniu, iar în rândul surselor multiple de celule stem, MSCs derivate din matricea ombilicală umană, și anume, gelatina Wharton (WJ), au fost propuse ca o nouă sursă potențială de celule care pot fi utilizate pentru tratamentul bolilor cardiovasculare (CVD) și în cazul terapiilor pentru cancer.[9]

Datorită descoperirii caracteristicilor excepționale ale MSCs și a încurajării de a implica MSCs atât în studii pre-clinice cât și clinice, se acceptă acum pe scară largă faptul că MSCs vor oferi un avantaj revoluționar în viitorul apropiat în intervenția terapeutică a diferitelor boli sau în regenerarea țesuturilor.

Rezultatele multiplelor studii clinice și pe animale (dar nu toate) au evidențiat potențialul de îmbunătățire a neovascularizării, reducerea cicatricilor și recuperarea funcțională atunci când se folosesc MSCs. Mai mult, modelele *in vitro* și *in vivo* sugerează că MSCs grăbesc angiogeneza post-ischemică și formarea vaselor de sânge. [25]

Cu toate acestea, o capcană majoră a terapiei cu MSCs este grefarea scăzută a celulelor transplantate în zonele infarctizate, adică circa 0,5% din MSCs transplantate au rămas în miocard după 4 zile.[10] Deși calea de administrare, adică intravasculară sau intra-cardiacă, poate explica diferențele, grefarea sau integrarea MSCs rămâne procentual scăzută (între 1-3%).[11]

Deficiențele profunde în înțelegerea mecanistică a reparațiilor și regenerării cardiace mediate de MSCs rămân încă un obstacol în avansarea, optimizarea și implementarea terapiei cu acest tip de celule.

Constatările de mai sus evidențiază nevoia crescută de optimizare a terapiei cu MSCs. În plus, identificarea moleculelor speciale pentru a putea pre-condiționa MSCs în scopul creșterii eficienței lor de adaptare și retenție și de a migra sau a fi redirecționate către locul potrivit (leziune sau țesut ischemic) rămâne o mare provocare, însă reprezintă și o caracteristică importantă pentru regenerarea țesutului sau organului respectiv .[12]

În sistemul reproductiv, estradiolul declanșează remodelarea țesuturilor, prin urmare, este posibil ca acest hormon sexual să faciliteze procesele de protecție, inclusiv repararea leziunilor ischemice. Se presupune că estrogenii pot facilita procesele biochimice și celulare în MSCs, generând factori paracrini, care facilitează grefarea și integrarea MSCs, astfel, ajutând la repararea cardiacă.

Un alt tip de celule cu potențial angiogenic sunt celulele endoteliale progenitoare (EPCs) obținute fie din surse fetale, fie din sânge periferic.

EPCs au fost descrise pentru prima dată de către Asahara et al [20] ca fiind celule $CD34^+$, care sunt capabile să participe la procesele de vasculogeneză; de atunci, biologia EPCs a câștigat o atenție deosebită și rapidă.

Pentru a recrea un endoteliu sănătos, este necesar a se lua în considerare o sursă exogenă de EPCs mai tinere și mai sănătoase. Pentru a atinge acest obiectiv, EPCs derivate din sângele din cordonul ombilical ar putea reprezenta candidații potriviți pentru re-endotelializarea vaselor cărora li s-a aplicat un tratament vascular sau au suferit o leziune.

Aceste tipuri noi de celule endoteliale sunt relativ ușor de obținut, au un potențial proliferativ ridicat, sunt potrivite pentru transplant și posedă o toleranță imună care permite transplantarea cu succes în ciuda disparității antigenului leucocitelor umane (HLA), sau se pot potrivi de la donator la pacientul primitor prin utilizarea HLA-urilor prezente și cunoscute.[14,15]

iCelulele din sângele cordonului ombilical pot, de asemenea, să se dividă și să formeze un număr de celule de 100 de ori mai mare comparativ cu numărul de celule obținut din sângele periferic, și să aibă o cantitate semnificativ mai mare de activitate telomerazică.[16]

Motivele posibile pentru care nivelurile de EPCs scad odată cu vârsta includ o capacitate redusă de a se mobiliza sau de a se diferenția și/sau epuizarea celulelor stem/progenitoare din măduva osoasă. EPCs pot avea o sensibilitate crescută la apoptoză din cauza unui dezechilibru între factorii pro- și anti-apoptotici și/sau scăderea apărării împotriva radicalilor liberi. Dovezi recente au arătat că EPCs derivate din măduva osoasă sunt direcționate spre locurile cu leziuni vasculare și aderă la peretele vascular rănit pentru a recrea un strat endotelial intact.[17,18] Creșterea numărului de EPCs circulante după administrarea de statine, estrogen, VEGF, G-CSF și efectuarea exercițiilor fizice, au arătat o re-endotelializare îmbunătățită după lezarea vasculară.[19,20]

De asemenea, odată cu trecerea anilor, studii recente au arătat că procesul de îmbătrânire este mediat de către 17-beta estradiol. Acest hormon sexual a demonstrat efectele sale benefice prin reducerea senescenței EPCs datorită scăderii receptorului angiotensinei de tip 1[21] și prin promovarea activității telomerazei.[22]

Luând în considerare datele existente în literatura de specialitate, **scopul** acestui proiect cuprins în teza de doctorat a fost evaluarea rolului hormonului estrogenic 17-beta estradiol (E2) asupra adeziunii, proliferării, migrării și încorporării în țesutul cardiac a celulelor stem obținute din sânge de cordon ombilical (celule endoteliale progenitoare) și din gelatina Wharton (celule

stem mezenchimale) și descifrarea mecanismelor moleculare implicate în procesele de angiogeneză, remodelare și regenerare tisulară folosind sisteme *in vitro*, *ex-vivo* și *in vivo*.

Prezenta teză de doctorat conține **2 studii majore**.

În **prima parte** a tezei de doctorat - **Stadiul actual al cunoștințelor** - organizată în 4 capitole, sunt prezentate noțiuni teoretice referitoare la caracterizarea, efectele biologice și mecanismele de acțiune ale estrogenilor și receptorilor estrogenici. De asemenea, sunt prezentate posibilitățile terapeutice existente, dar și necesitatea dezvoltării unor noi strategii terapeutice ce implică utilizarea unor tipuri de celule stem considerate posibili agenți terapeutici în bolile cardiovasculare.

În a doua parte a lucrării de doctorat - **Contribuții originale** - cercetările noastre au fost concentrate în două studii majore legate de efectul E2 asupra proliferării, migrării/integrării MSCs sau EPCs în regenerarea țesutului cardiac (studii *in vitro, ex vivo* și *in vivo*).

Deoarece estrogenii stimulează creșterea și activitatea celulelor cardiovasculare[23,24], împreună cu faptul că promovează creșterea și angiogeneza în celulele endoteliale progenitoare și în celulele stem[25,26], **primul nostru obiectiv** a fost să identificăm dacă E2 poate facilita/crește adeziunea și proliferarea MSCs/EPCs și dacă caracterul de celulă stem al MSCs/EPCs este păstrat și după tratamentul cu hormonul sexual. Pentru a atinge acest obiectiv, în primul rând, am izolat și caracterizat MSCs/EPCs din gelatina Wharton și sângele cordonului ombilical, apoi am testat concentrația optimă de E2 pentru aceste tipuri de celule stem.

Recent, rezultatele multor studii oferă dovezi că E2 influențează biologia și fiziologia vasului de sânge și a inimii, prin interacțiunea directă cu celulele vaselor de sânge (celulele musculare netede, celulele endoteliale) și cu a celulelor existente în inima (miocite și fibroblaste) prin intermediul receptorilor estrogenici (ERs), ER-alfa și ER-beta. Prin urmare, **cel de-al doilea obiectiv** a fost de a elucida rolul celor doi ERs, în medierea efectelor anterior menționate.

Mai mult, **al treilea obiectiv** a fost acela de a examina prin analiza proteomică potențialele procese pro-reparatorii, căile și mecanismele afectate de modificările pe care le-ar putea provoca E2 în MSCs după tratamentul adecvat cu acest hormon.

Un **al patrulea obiectiv**, l-a constituit confirmarea și/sau validarea datelor obținute *in vitro*, iar pentru îndeplinirea acestui obiectiv, am procedat la studiul *in vivo* pe animale de laborator.

În concluzie, studiile noastre s-au axat pe elucidarea potențialului de adeziune, proliferare și/sau a mecanismelor apărute în urma expunerii MSCs/EPCs la tratamentul cu E2, tratament ulterior ce poate spori capacitatea celulelor stem de a repara/regenera țesutul cardiac lezat.

Concluzii generale obținute în cadrul prezentei teze de doctorat

1. Celulele umane (folosite în studiile noastre) supuse stimulării cu E2 ar putea constitui un instrument util în tratarea leziunilor cardiace, în special la femei.

2. Utilizarea celulelor stem provenite din sângele de cordon ombilical și gelatina Wharton tratate cu estradiol poate fi o alternativă utilă pentru depășirea limitărilor terapeutice pentru tratarea leziunilor cardiace la femei.

3. Accesul facil și cultivarea MSCs sau EPCs din sursele alese în studiile noastre ocolește problemele etice cu care se confruntă celulele stem embrionare.

4. Infuzarea celulelor tratate cu estradiol pentru o scurtă durată (48 ore) ar limita riscul de carcinogeneză asociată estrogenului și ar permite tratarea leziunilor cardiace.

5. Mecanismele celulare, biologice și moleculare identificate în celulele umane tratate cu estradiol utilizând screening-ul proteomic, pot oferi noi perspective în înțelegerea și dezvoltarea strategiilor de optimizare a tratamentului miocardului lezat, mai ales la femei.

6. Boala cardiovasculară crește în cazul femeilor aflate la menopauză, perioadă caracterizată prin scăderea nivelului de estrogeni. Deoarece subiecții din acest grup au o mare probabilitate de a suferi boli de inimă pentru care necesita tratament, stimularea celulelor izolate din surse fetale cu estrogen, precum și pre-tratamentul subiecților de sex feminin, ar putea favoriza grefarea celulelor, rezultând o refacere eficientă a funcției cardiace.

7. Elaborarea unui sistem *in vitro* original, **brevetat** de noi și aplicat celulelor endoteliale progenitoare supuse tratamentului cu hormonul sexual E2, care demonstrează în timp real migrarea și interacțiunea celulă-celulă (tehnica de "scratch/wound healling"), proces modulat de prezența antagonistului de moleculă.

I. Premize

Bolile non-comunicabile (ateroscleroza, diabet, obezitate, cancer) reprezintă una din cauzele majore de mortalitate in lume, inclusiv in tara noastra. Componenta comună a acestor maladii este inflamația. Proiectul INTERA a urmărit stabilirea unor metode terapeutice inovative care, prin reducerea procesul inflamator să amelioreze procesele patologice. INTERA a inclus studii multi- si transdisciplinare pentru crearea si definirea unor noi nano- sau micro-dispozitive medicale utilizabile pentru terapii anti-inflamatoare inteligente si inovatoare. INTERA a inclus patru proiecte:

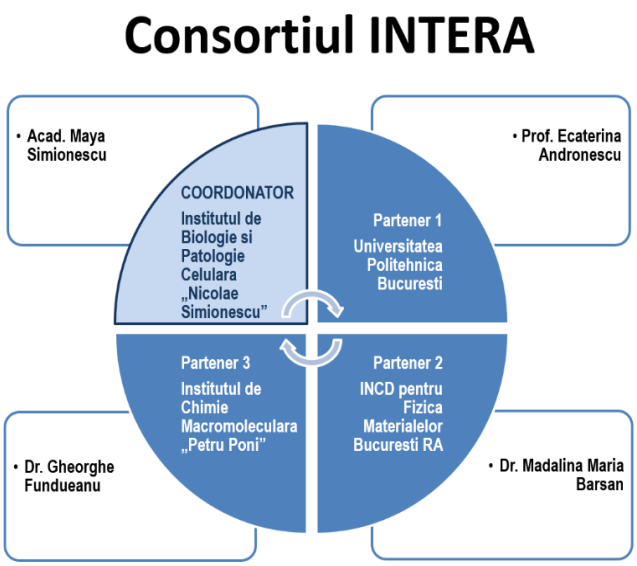
(1) Încapsularea celulelor eucariote manipulate genetic pentru eliberarea controlată a unor produși farmacologici activi;

(2) Conceperea unei platforme 3D compusa din celule incorporate in bio-matrici tridimensionale pentru testare pre-clinica de medicamente;

(3) Nanobioparticule inteligente concepute pentru vectorizarea compușilor bioactivi către situsuri patologice pentru terapia inflamației vasculare;

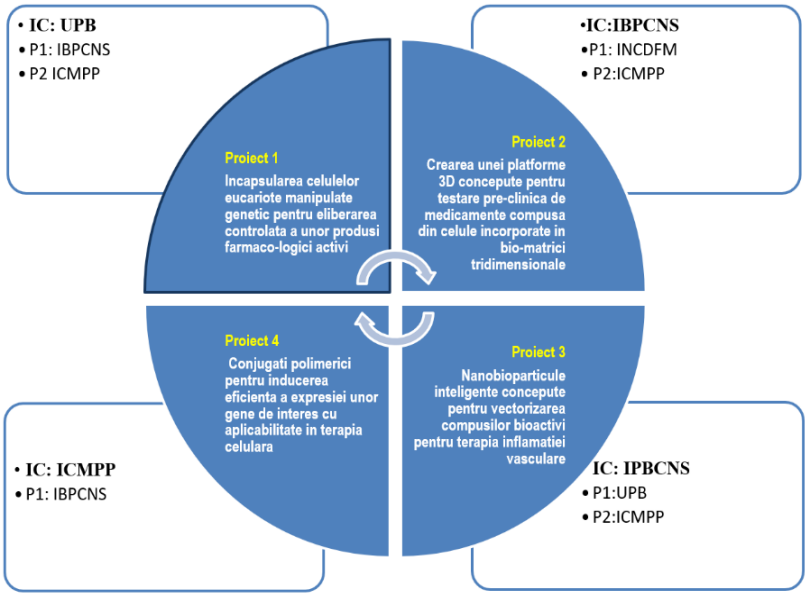
(4) Conjugati polimerici pentru inducerea eficienta a expresiei unor gene de interes cu aplicabilitate in terapia celulara.

Consorțiul INTERA este format din 4 unități de cercetare partenere – doua institute ale Academiei Romane (IBPCNS, ICMPP), o universitate (UPB) si un institut national de CD (INCDFM) cu o buna acoperire teritoriala (București-Ilfov-Iași). Partenerii cu profil de specializare similar (UPB, INCDFM, ICMPP) sau complementar (IBPCNS / UPB, INCDFM, ICMPP) asigura utilizarea unor tehnologii multidisciplinare permițând realizarea unor produse inovative micro-/nano-terapeutice si dezvoltarea de tehnologii nano-farmaceutice. Toate instituțiile partenere au realizat infrastructuri de cercetare noi prin fondurile structurale. Prin implementarea INTERA, fiecare instituție si-a dezvoltat si mai puternic capacitățile proprii.



Agenda comuna

Proiectele componente INTERA



Proiectele din cadrul INTERA sunt proiecte de interes actual si de viitor, fiind la intersecția unor domenii de cercetare abordate de instituțiile partenere.

Aceste strategii de cercetare sunt incluse in programele de cercetare ale instituțiilor partenere, urmărind dezvoltarea de studii multi- si transdisciplinare care doar împreuna pot crea si defini noi nano- sau micro-dispozitive medicale utilizabile pentru terapii anti-inflamatoare inteligente si inovatoare.

Dezvoltarea unor noi competente, dar si îmbunătățirea celor existente in unitățile partenere va atrage atenția mediului economic, spre o mai buna corelare a intereselor științifice cu cele economice, dar si o mai buna valorizare in domeniul științei medicamentelor, prin oferirea rezultatelor cercetării mediului economic (companii farmaceutice sau micro-întreprinderi cu profil biotehnologic). Din punct de vedere social, dezvoltarea instituționala in domeniul de cercetare deschis de proiectul INTERA va conduce la noi abordări terapeutice, mult mai accesibile populației datorita unui cost mai scăzut, având implicații majore in îmbunătățirea calității vieții.

Concret, la baza programului comun de CDI stau rezultatelor obținute prin implementarea proiectului INTERA si dezvoltarea capacitații instituționale a partenerilor: Pe baza rezultatelor obtinute pana acum, ne propunem sa continuam si extinde colaborarea noastra, avand o serie de obiective dintre care unele sunt enumerate mai jos.

1. Consolidarea si extinderea competentelor științifice si tehnice. Instituțiile participante la INTERA au un profil științific complementar. Astfel fiecare instituție a putut dezvolta noi tehnologii care îmbina diferite ramuri științifice, importând anumite tehnologii de la unitățile partenere. In același timp, instituțiile cu profil similar au beneficiat de

schimburi de experiența si de competenta, astfel încât si-au putut îmbunătăți reciproc activitățile științifice si tehnice. Implementarea proiectului a condus la creșterea competențelor de cercetare în domeniul Nanomedicinei și Biomaterialelor a instituțiilor partenere și la creșterea vizibilității pe plan internațional prin publicarea rezultatelor comune în reviste cotate ISI. Acest fapt va avea drept consecință in continuare atragerea resursei umane și creșterea colaborărilor cu alte grupuri de cercetare din țară și din străinătate.

2. Creșterea numărului de tineri implicați in cercetare si specializarea acestora. Cele 10 noi locuri de munca in cercetare si pregătirea tinerilor pentru cercetare reprezintă un beneficiu al instituțiilor participante in proiectul INTERA, suplinind o parte din deficitul de personal si asigurând buna funcționare a infrastructurilor de cercetare create anterior. Proiectul INTERA a constituit o platformă pentru instruirea și calificarea tinerilor nou angajați care au beneficiat de transferul de cunoștințe de la cercetătorii cu experiență. Au fost cooptați cercetători din afara proiectului care fac parte din alte instituții, cum ar fi UMF Iași, in realizarea unor teme specifice, crescând interesul pentru subiectele dezvoltate in cadrul proiectului INTERA ceea ce a facilitat oportunități comune de dezvoltare a unor noi proiecte de cercetare. Astfel, preconizăm creșterea capacității de cercetare a echipelor din instituțiile partenere, dezvoltarea de arii noi de cercetare bazate pe noi abordări bio-nano-tehnologice și intensificarea competitivității și vizibilității cercetării din România.

3. Creșterea numărului de produsele tehnologice, serviciile noi sau îmbunătățite, cererile de brevet, prezentări la saloanele de inventica, lucrările publicate. Rezultatele emergente din proiectul INTERA stau la baza unei interactii mult mai eficiente cu mediul economic. Ofertele de servicii noi de cercetare si tehnologice au fost postate in platforma ERRIS, pentru o mai buna vizibilitate. Participarea la Saloane Naționale și Internaționale de inventică cu brevetele rezultate în cadrul proiectului INTERA a dus la recunoașterea valorii acestor brevete prin acordarea a numeroase premii și a explorat interesul pentru a dezvolta produsele și tehnologiile patentate. Valorificarea si difuzarea rezultatelor de cercetare precum si acordarea de asistenta de servicii științifice si tehnologice în domeniul prioritar Bioeconomie vor sta la baza colaborării unităților partenere. Fezabilitatea parteneriatului este asigurata de experiența cercetătorilor, de existenta resurselor materiale si de datele experimentale acumulate ale participanților.

4. Utilizarea eficienta a infrastructurii din instituțiile partenere. Instituțiile partenere INTERA vor beneficia in continuare de infrastructurile îmbunătățite ale consorțiului, folosindu-se potențialul material al partenerilor pentru a asigura Programul Comun de cercetare dezvoltare si inovare (CDI). Infrastructura existenta in cadrul instituțiilor partenere si a celor noi cooptate permite continuarea cercetărilor aplicative axate pe produșii proiectați si sintetizați in cadrul proiectului INTERA, permițând si testarea *in vitro* si *in vivo*, dar si dezvoltarea unor aplicații diferite de cele preconizate care pot fi sursele unor noi idei de cercetare-dezvoltare.

Infrastructurile sunt evidențiate pe site-ul ERRIS astfel:

- Institutul de Biologie si Patologie Celulara „Nicolae Simionescu” https://eeris.eu/ERIO-2000-000Z-0136

- Universitatea Politehnica din București - UPB, https://eeris.eu/ERIF-2000-000H-0593

- Institutul Național de Cercetare-Dezvoltare pentru Fizica Materialelor – INCDFM https://eeris.eu/ERIO-2000-000Y-0145

- Institutul de Chimie Macromoleculara “Petru Poni”, https://eeris.eu/ERIO-2000-000V-0034

II. Stadiul curent al colaborării si modalități de continuare si extindere

Pe lângă proiectul INTERA, cercetătorii din instituțiile din acest consorțiu au mai participat impreuna la alte proiecte de cercetare cum sunt:

- *Apolipoproteine generate prin inginerie genetica imobilizate pe nanoparticule - un cal troian molecular pentru țintirea plăcii aterosclerotice,* proiect PN-II-RU-TE-2014-4;

- *Evaluarea potențialului terapeutic al transferului genic non-viral al apolipoproteinei E pentru limitarea progresiei aterosclerozei*, proiect PN-III-P1-1.1-PD-2016-1942;

- *Biologically Inspired Systems for Engineered Structural and Functional Entities,* proiect PN-II-ID-PCCE-2011-2-0028 (http://www.intelcentru.ro/Biomimetics_PCCE/);

- *Mimarea mecanismelor viului prin abordări ale chimiei supramoleculare, in cinci dimensiuni,* proiect PN-III-ID-PCCF-2016.

- *Măsurarea in timp real a efectului fasciculului de protoni indus de laser asupra celulelor umane:* PN-III-P5/Subprogramul 5.1/ELI-RO; 189/18.10.2017 (2017-2019)

Bazele unor astfel de cercetări multidisciplinare in colaborare, constituie etapele premergătoare unor proiecte mai mari. Toate aceste acțiuni vor conduce la acumularea unor noi cunoștințe ale personalului implicat, prin relații de colaborare cu cercetători din domenii conexe, cum ar fi medicina, biologie si fizica. Aceste activități stau la baza continuării si extinderii colaborărilor dintre parteneri si vor conduce inerent la depunerea unor noi proiecte de cercetare științifică, necesare pentru finanțarea transferului tehnologic a rezultatelor cercetării fundamentale.

Oportunitățile de finanțare in acesta perioada in Romania sunt limitate, însă vom încerca sa obținem atât finanțări naționale cat si finanțări europene sau din alte surse. Consorțiul își propune sa aplice in apeluri pentru proiecte de cercetare naționale si internaționale. Consorțiul va beneficia de strategia de abordare a surselor de finanțare a ICMPP, care cuprinde: dezvoltare a capacității organizatorice si manageriale a activității de cercetare: STREAM, dezvoltarea infrastructurii de cercetare INTEl Centru si dezvoltarea resursei umane: Fondul Social European - Program de burse postdoctorale Cristofor I. Simionescu .

De asemenea, o atenție deosebita este acordata CLUSTERILOR. Astfel, in acest moment atât ICBPNS cat si UPB sunt membrii ai clusterului **AngioNET,** însă in viitorul apropiat si ceilalți parteneri vor adera la acest cluster care urmărește să genereze și să aplice inițiative și activități legate de sănătate și mediu, sa promoveze și încurajeze inovarea prin cooperarea între companii, organizații, universități, entități publice și transferul cunoștințelor în vederea creșterii calității serviciilor medicale în domeniul bolilor cardiovasculare și oncologice în România.

III. Domenii de dezvoltare ale planului comun CDI

Domeniul Sănătății este considerat un domeniu de cercetare prioritar, fiind încadrat in Programul Horizon Europe 2021- 2027/ Pilonul 2 Provocări globale si competitivitate industriala europeana si in Strategia Națională de Sănătate 2014 – 2020. Cercetarea actuala in domeniul biomedical se poate obține numai prin colaborări reale, prin multi- si transdisciplinaritate si convergenta activităților CDI.

Așa cum a fost asumat in propunerea de proiect, pe baza expertizei realizate in cadrul derulării proiectului INTERA, a fost conturat un program comun de dezvoltare sustenabila a activităților CDI pentru perioada post-implementare a proiectului, in vederea continuării colaborărilor dintre echipele partenere, după finalizarea proiectului. Aceasta continuare a activităților științifice se va realiza prin proiecte de cercetare comune cu care se va participa la competiții de granturi naționale si internaționale.

Datorită complexității obiectivelor de cercetare este necesară colaborarea unor echipe de cercetare cu competente interdisciplinare și accesul la infrastructura de cercetare existentă în instituțiile partenere. In acest sens, cooperarea instituționala este un instrument esențial in activitatea de cercetare, implicând menținerea colaborărilor deja stabilite între echipele de cercetare din instituțiile partenere pentru o realizare cât mai eficientă a obiectivelor de cercetare ale fiecărei instituții în parte. Majoritatea activităților științifice propuse va implica consorțiul existent (integral sau parțial) însă extinderea consorțiului va permite o specializare suplimentară și implicit optimizarea avansată a soluțiilor propuse. Obiectivul major este consolidarea unui nucleu cu competențe științifice si tehnologice în domeniul nanoparticulelor cu potențial de direcționare, a vectorilor non-virali și a materialelor avansate ce răspund la nevoile nanomedicinii în tratamentul bolilor non-comunicabile (de ex. boli cardiovasculare, respiratorii, cancer). De asemenea, se are in vedere diversificarea gamei de servicii de cercetare și transferul acestora către partenerii industriali, în scopul stimulării competitivității cercetării științifice românești la nivel european și a competitivității economice naționale ale institutelor de cercetare implicate în domeniul de specializare inteligentă.

Majoritatea activităților științifice propuse vor implica consorțiul existent (integral sau parțial) dar gândim si la extinderea consorțiului care va permite o specializare suplimentară și implicit optimizarea avansată a soluțiilor propuse.

Obiective specifice previzionate pentru **colaborări viitoare**:

- **Realizarea unor cercetări științifice avansate, asigurată de complementaritatea consorțiului** atât din punct de vedere al resursei umane cât și a infrastructurii de cercetare;

- **Creșterea competitivității cercetării românești** la nivel național și internațional, prin crearea unui nucleu de cercetare cu competență științifică și tehnologică de nivel înalt, prin colaborare inter-instituțională cu competente științifice si infrastructura conexe

- **O mai buna valorificare a rezultatelor cercetării** prin introducerea acestora în circuitul economic sub formă de produse, procese și servicii noi. Stimularea transferului tehnologic prin crearea de parteneriate cu IMM-uri.

- **Creșterea vizibilității internaționale** și a implicării nucleului de cercetare nou creat în proiecte europene.

- **Creșterea calității resursei umane** prin i**nstruirea și calificarea tinerilor in domeniul cercetării biomedicale,** prin schimburi de experiența si prin dezvoltarea de teze de doctorat în cotutelă;

- **Susținerea reciprocă a tinerilor cercetători postdoctoranzi** (beneficiari ai unor proiecte PD) în vederea realizării proiectelor;

- **Crearea de noi locuri de muncă** și asigurarea condițiilor optime de desfășurare a activităților CDI

- **Aderarea comuna la clusteri pentru a extinde expertiza**, accesul la infrastructura de cercetare specifica si creșterea vizibilității naționale si internaționale in vederea accesului la finanțările națională si internaționale

- **Organizarea și participarea la evenimente științifice**, precum workshop-uri si cursuri postuniversitare.

Activitatea de cercetare va continua pe tematicile proiectului INTERA, însă se vor aborda si teme emergente sau noi. Prezentul program comun de CDI, corelat cu planurile de dezvoltare instituțională ale partenerilor INTERA este in concordanta cu Propunerea Comisiei Europene privind Horizon Europe 2021 - 2027 si cu Strategia Națională pentru Dezvoltare Durabila a României 2030.

Direcțiile principale de cercetare vor fi:

1. Materiale polimerice avansate cu aplicații biomedicale

Dezvoltarea științei polimerilor si versatilitatea acestora a dus la o larga utilizare in domeniul biomedical si biotehnologic atât al polimerilor naturali cât si a celor sintetici. Combinarea proprietăților polimerilor naturali cu cele ale polimerilor sintetici a dus la obținerea unor materiale cu caracteristici superioare. Aceste materiale polimerice vor fi transformate in matrici hibride multicomponente, retele semi- sau inter-penetrate, polimeri grefați, bloc copo-

limeri, polimeri sensibili la stimuli externi, polimeri cu amfifilie variabilă, polimeri cu amprenta moleculara, polimeri biomimetici. Biomateriale avansate cu proprietăți fizico-chimice si biologice controlate se vor utiliza sub forma de suporturi macromoleculare (micro- si nanoparticule/capsule) pentru reținerea si eliberarea controlata de medicamente, pentru trimiterea dirijata "la ținta" a medicamentelor /ADN, suporturi "inteligente" pentru eliberarea cu autoreglare a principiilor active, hidrogeluri biomimetice pentru ingineria (regenerarea) diferitelor tesuturi (osos, muscular, epitelial, etc).

Obiectivele specifice ale acestor cercetări sunt:

- conceperea si dezvoltarea unor surogate de țesuturi normale si tumorale prin creșterea de celule pe suporturi macromoleculare cu porozitate controlata. Aceste țesuturi surogat pot ajuta la măsurarea *in vitro* a eficientei unui medicament in timpul stadiilor preclinice de dezvoltare a medicamentului sau pot sa fie utilizate pentru studierea pato-biologiei tumorilor (*in vitro*) prin monitorizarea proliferării celulelor canceroase, invaziei, remodelarea matricilor, angiogenezei sau metastazelor.

- obținerea de polimeri sintetici si naturali modificați chimic, cu arhitecturi complexe (hidrogeluri, filme, micro- si nano-particule/capsule) pentru eliberarea controlata a medicamentelor, pentru trimiterea dirijata "la ținta" a medicamentelor (ADN), ca suporturi biomimetice pentru ingineria (regenerarea) diferitelor țesuturi (osos, muscular, epitelial, etc.) sau pentru înglobarea/creșterea de celule.

- dezvoltarea de tuburi pe bază de alginat (sau alți polimeri) pentru aplicații cardiovasculare atât ca sistem suport pentru regenerare cât și ca sistem cu eliberare controlată pentru tratamente multiple;

- ranforsarea matricilor de alginat cu nanoparticule magnetice funcționalizate și exploatarea sinergismului dintre acestea.

- utilizarea oxidului de grafenă în formă pură cât și în compozite complexe cu potențial regenerativ și medicamentos.

- perfecționarea tehnologiei de obținere a fibrelor electrofilate pentru realizarea de plase electrofilate din diverși polimeri biocompatibili. De asemenea, se vor perfecționa procedeele de electrofilare având ca precursori coplomeri biocompatibili, in vederea obținerii de plase electrofilate de o robustețe si elasticitate sporite. Platformele 3D flexibile obținute vor fi funcționalizate cu diverse metale si/sau polimeri conductori care astfel vor avea un rol dual: i) suport pentru incorporarea de celule si ii) senzor electrochimic. Plasele electrofilate metalizate si populate cu celule vor permite efectuarea in-situ de măsurători electrochimice ale răspunsului celulelor vasculare in diverse biomatrici tri-dimensionale. Se vor dezvolta senzori electrochimici care sa fie suport pentru diverse tipuri celulare, si care vor putea monitoriza procese metabolice celulare prin detectarea unor metaboliți intracelulari ca de exemplu adenozin trifosfat, nicotinamidă-adenină dinucleotidă, dar și oxigen, superoxid, dioxid de carbon sau glucoză.

2. Sisteme de livrare de agenți terapeutici bazate pe nanoparticule

Cercetarea in acest domeniu se concentrează pe dezvoltarea unor terapii avansate bazate pe nanotehnologie pentru atenuarea bolilor cardiovasculare.

Obiectivele specifice ale acestor cercetări sunt:

- Dezvoltarea de nanoterapii direcționate către endoteliul vascular și monocite/macrofage pentru a reduce inflamația vasculară folosind modele experimentale pre-clinice de inflamație și ateroscleroză. Se are în vedere obținerea de nanocărăuși capabili de transport dirijat și livrarea eficientă la țintă a agenților farmaceutici sau de secvențe de siRNA/shRNA pentru silențierea genică;

- Testarea nanocărăușilor biomimetici structurali și funcționali și a nanoplatformelor capabile să acționeze ca vehicule de transfecție genetică;

- Dezvoltarea de platforme magnetice cu potențial în tratamentul unor boli cardiovasculare;

- Exploatarea nanocărăușilor magnetici în vederea dezvoltării de sisteme cu eliberare controlată, cu internalizare superioară în celule și eliberare țintită declanșată electromagnetic pentru diversele substanțe biologic active;

- Sortarea nanoparticulelor (conform cererii de brevet comune) și utilizarea nanoparticulelor cu caracteristici predefinite pentru aplicații țintite;

- Utilizarea nanoparticulelor cu miez de oxid metalic in abordarea teranostica a terapiei cancerului, prin care nanoparticulele pot fi agenți de livrare a unor medicamente antitumorale, factori de scăderea a stresului oxidativ si agenți de contrast.

IV. Rezultatele preconizate ale colaborării

I.**Stimularea capacității de inovare prin abordarea unor teme cu grad de complexitate crescut.** Realizarea unor proiecte multidisciplinare in domeniul biomedical, cu rezultate concrete si cu un grad mare de aplicabilitate.

II.**Corelarea si coordonarea activităților si resurselor pentru o mai buna valorificare a rezultatelor la nivel economic si social.** Valorificarea potențialului de cercetare pentru realizarea proiectelor complexe, multidisciplinare, de înalta dificultate. Proiectele emergente ale partenerilor consorțiului vor asigura realizarea unor dispozitive terapeutice inovative, cu un real impact social asupra îmbunătățirii sănătății si, ca urmare, a creșterii nivelului de trai.

III.**Creșterea competitivității si vizibilității instituțiilor partenere la nivel internațional,** care sa faciliteze cooptarea in consorții si clustere naționale si internaționale;

IV.Dezvoltarea unor noi proiecte care sa conducă la **crearea unor noi locuri de munca si continuarea activității de formare a tinerilor cercetători** prin accesarea de fonduri din programe de cercetare naționale si europene;

V.Realizarea unor competentele noi, abilitățile practice si experiența in cercetare acumulate vor contribui la consolidarea si **extinderea capacităților instituționale.** Aceasta va crea condiții pentru accesare si obținere de resurse financiare alternative si complementare de sprijinire a activității de cercetare;

VI.**Accesul la infrastructura din instituțiile partenere si îmbunătățirea infrastructurii instituționale**;

VII.**O mai buna valorificare si difuzare a cunoștințelor, competentelor si rezultatelor cercetărilor**. Creșterea capacitații de diseminare si dezvoltarea abilitaților de comunicare ale cercetătorilor va aduce beneficii directe comunității științifice academice din domeniul farmacologiei celulare si moleculare si clinicienilor care vor putea prelua rezultatele noastre si folosi ca metoda concept pentru alte tratamente inovative. O categorie importanta de beneficiari direcți o reprezintă companiile si firmele medicale (in special mici si mijlocii), laboratoarele de cercetare biomedicala naționale sau internaționale cu care deja cooperam sau intenționam sa colaboram. Prin schimburi de idei si colaborări intre comunitățile științifice si economice, rezultatele vor putea fi transferate din mediul științific in practica medicala si industriala. Pe plan socio-economic, in viitor, beneficiarii direcți vor fi pacienții cu maladii grave in care procesul inflamator este predominant. Pentru acești pacienți, nanoterapia si intervențiile folosind biomateriale ar putea reprezenta alternative non-invazive la terapiile invazive existente. In plus, costul social deosebit de mare al bolnavilor cu maladii cardiovasculare ar putea fi redus substantial.

VIII.Creșterea numărului de cereri de patente si o mai buna cunoaștere a nevoilor inovative, prin **inițierea si dezvoltarea de colaborări viabile cu parteneri din mediul economic si privat.** Dezvoltarea cercetărilor translaționale in instituțiile partenere si transferul rezultatelor cercetărilor către companii farmaceutice, in special IMM.

IX.**Creșterea gradului de implicare si vizibilitate pe plan internațional.** Articolele științifice publicate în reviste cotate WoS cu factor de impact reprezintă premizele majore pentru creșterea vizibilității cercetării românești. Ne propunem sa publicam rezultatele originale obținute de partenerii din proiect dar numai după brevetarea/ valorificării lor prin licențiere sau prin înființarea de firme spin-off/start-up sau participarea la saloane de inventica, naționale/ internaționale. Aceasta va asigura si dreptul la proprietate intelectuala si vizibilitatea rezultatelor cercetării romanești la nivel internațional.

X.**Creșterea capacitații de acordare de asistenta tehnica si de servicii tehnico - științifice de înalt nivel in domeniul prioritar Bioeconomie.** Vor putea fi oferite altor unități din domeniu noi servicii științifice si tehnologice de înalt nivel, datorita noilor tehnologii implementate de către consorțiul INTERA. Introducerea unor noi tehnologii in instituțiile partenere va conduce la specializarea echipelor in aceste tehnici si la asigurarea noilor servicii oferite altor cercetători din tara, care vor fi afișate pe site-ul ERRIS.

RAPORT STIINTIFIC FINAL

Denumirea proiectului: Imbunatatirea proprietatilor paracrine ale fibroblastelor prin agregare tridimensională pentru terapia ranilor cronice

Cod proiect: PN-III-P1-1.1-TE-2021-1344

Numar contract: 149/2022

Perioada de raportare: 9.06.2022 – 7.09.2024

Scopul acestui proiect a fost de a determina daca fibroblastele pot fi o sursa alternativa in terapia de regenerare fara celule, prin imbunatatirea prorietatilor lor paracrine prin declansarea nemozei indusa in cultura tridimensionala. Pentru a atinge acest scop, am avut mai multe obiective: (1) evaluarea proprietatilor secretomului recoltat de la sferoizii derivati din fibroblaste asupra procesului de vindecare a ranilor in vitro, (2) evaluarea modificarii proprietatilor pro-angiogene induse de procesul de agregare a fibroblastelor, (3) evaluarea proprietatilor anti-inflamatorii induse de procesul de agregare si (4) validarea efectelor observate pe model murin de rani excizionale. Un obiectiv aparte l-a constituit Managementul si Diseminarea rezultatelor proiectului.

Proiectul s-a desfasurat in 3 mari etape:

Etapa 1: Evaluarea in vitro a proprietatilor de vindecare a ranilor a secretomului recoltat de la sferoizi derivati din fibroblaste;

Etapa 2: Determinarea proprietatilor pro-angiogene si anti-inflamatoare induse in fibroblaste de procesul de agregare;

Etapa 3: Validarea efectelor benefice in vindecarea ranilor a secretomului recoltat de la sferoizi derivati din fibroblaste pe model animal de rana excizionala.

In urma analizei rezultatelor obtinute in proiect, s-au demonstrat urmatoarele:

In prima etapa a fost selectat secretomul recoltat de la fibroblaste crescute in sferoizi derivati din 25.000 de celule, care a prezentat un potential crescut de a contribui la vindecarea ranilor cutanate, prin sustinerea urmatoarelor procese celulare: inducerea proliferarii si a migrarii keratinocitelor si a fibroblastelor dermale umane, inducerea formarii matricei extracelulare prin stimularea sintezei unor proteine componente ale acesteia precum colagenul de tip I si biglicanul, si prin inhibarea expresiei genice a metaloproteinazelor matriceale si prin stimularea chemoatractiei keratinocitelor.

In cadrul celei de-a doua etape, s-a demonstrat ca sistemul de cultura tridimensionala a indus modificari in compozitia secretomului fibroblastelor dermale, rezultatele in vitro aratand o imbunatatire a capacitatii fibroblastelor dermale umane de a sustine vindecarea ranilor cutanate, accelerand procesul de re-epitelizare a ranii. Dintre rezultatele notabile obtinute in Etapa 2 mentionam:
- Prin agregare 3D a fost indusa/crescuta secretia unor factori pro-angiogeni, precum CXCL16, DPPIV, Endostatina, FGF7, HGF, IL-8, MCP-1, PIGF, Prolactina si VEGF. Consideram ca o

importanta deosebita o au: cresterea nivelului de VEGF si inducerea de novo a secretiei de IL-8, ambele fiind cunoscute molecule pro-angiogene.
- Rezultatele obtinute *in vitro*, dar si *in vivo* sugereaza ca modalitatile prin care mediul conditionat obtinut de la fibroblaste crescute in sistem 3D, dar si 2D, promoveaza procesul de angiogeneza, ,âsunt sustinerea migrarii celulare si chemoatractia. Inducerea maturarii vaselor de sange a fost sustinuta doar de modelul 3D;
- In modelul nostru experimental *in vitro* nu s-a observat o actiune pro sau anti-inflamatoare a mediului conditionat obtinut de la agregatele 3D, insa modificarile observate in profilul citokinelor inainte si dupa agregare sugereaza ca acesta ar putea avea un rol in modularea procesului inflamator, prin cocktailul de molecule cu rol atat de sustinere, cat si de inhibare a acestuia;
- A fost demonstrata implicarea procesului de nemoza in determinarea secretiei de citokine si factori de crestere a fibroblastelor crescute in sistem 3D.

In cadrul celei de-a treia etape, rezultatele obtinute in vitro au fost validate pe un model murin de rana excizionala, care a recapitulat fazele vindecarii pielii umane, inclusiv dezvoltarea unui tesut de granulatie, demonstrand ca poate fi folosit pentru o evaluare preclinica a unui posibil tratament.

Utilizand acest model, s-au observat urmatoarele:
- mediul conditionat obtinut de la fibroblaste crescute in sistem 3D a indus o inchidere a ranii mai rapida la 7 zile, comparativ cu controlul tratat cu DMEM si controlul mediul conditionat obtinut de la fibroblastele crescute in sistem 2D;
- S-a observat o maturare a vaselor de sange in cazul animalelor tratate cu mediul conditionat obtinut de la fibroblaste crescute in sistem 3D; acest lucru se coroboreaza cu rezultatele de evaluare a angiogenezei pe pat de Matrigel, raportat in etapa anterioara;
- S-a evidentiat o re-epitelizare mai rapida a tesutului lezat in cazul animalelor tratate cu mediul conditionat obtinut de la fibroblaste crescute in sistem 3D, acest rezultat fiind, de asemenea, in deplina concordanta cu rezultatele in vitro pe culturi de celule obtinute in etapele anterioare;
- S-a observat o remodelare mai rapida si mai intensa in cazul animalelor tratate cu mediul conditionat obtinut de la fibroblaste crescute in sistem 3D (Figura 1), sugerand o vindecare profunda a ranii mai rapida comparativ cu celelalte conditii, in concordanta cu rezultatele care aratau ca acest mediu induce o sinteza crescuta a colagenului de tip I in fibroblastele dermale cultivate in sistem clasic;

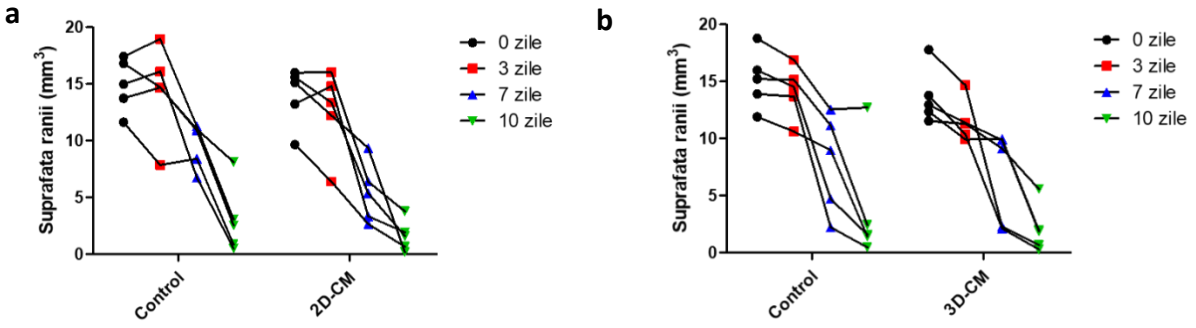


Figura 1. *Evolutia in timp a ranii pentru animalele tratate cu mediu conditionat recoltat de la fibroblaste crescute in sistem 2D, respctiv 3D.*

- Rezultatele sugereza un proces inflamator scazut la 7 zile la nivelul leziunii, in cazul animalelor tratate cu 3D-CM.

In **concluzie**, putem spune ca procesul de agregare a imbunatatit capacitatea fibroblastelor dermale umane de a sustine vindecarea ranilor cutanate intr-un model de rana pe model murin, accelerand procesul de re-epitelizare a ranii. Astfel, in cadrul acestui proiect, realizarea integrala a activitatilor propuse a dus la demonstrarea ipotezei, sustinand ideea ca fibroblastele ar putea constitui o sursa alternativa pentru terapia regenerativa fara celule, care utilizeaza produsii eliberati de acestea.

Atherosclerosis is a chronic inflammatory disease that affects elastic arteries (aorta, carotid, iliac) as well as muscular arteries (coronary, renal). Early in the last century, Nikolai Anitschkow discovered the role of plasma cholesterol in atherosclerosis development. Later the generation transgenic mice made possible experiments which revealed the role of apolipoproteins in atherogenesis.

Apolipoprotein E is a 35 kDa glycoprotein, synthesized mainly in the liver. However, ApoE is also produced in small amounts in other tissues and cells, including macrophages. ApoE makes an essential contribution in the lipoproteins metabolism as an either major or minor component. ApoE deficiency in animal models as well as in patients with type III hyperlipoproteinemia is associated with premature atherosclerosis. Low or absent expression of apoE in macrophages, leads to atherogenic process. However, transgenic mice expressing apoE only in macrophages do not develop atherosclerosis even when their plasma apoE levels are low and the animals are hypercholesterolemic. In contrast, transgenic mice with normal plasma apoE levels and no apoE expression in macrophages, are prone to atherosclerosis. Atheroprotective role of apoE is mainly due to the fact that apoE is involved in the clearance of atherogenic plasma lipoproteins (acting as a ligand for several members of LDL receptor family) and of the excess of cholesterol from cells (facilitating the reverse cholesterol transport to the liver). In addition, apoE has many other beneficial effects: is antioxidant, inhibits platelet aggregation, stimulates production of nitric oxide, inhibits T-cell activation, etc. ApoE is considered an important therapeutic target for the prevention and treatment of atherosclerosis for its modulation that could lead to major beneficial effects in the metabolism of lipoproteins.

Apolipoprotein CII is another plasma protein, associated with chylomicrons and VLDL particles. ApoCII is the main activator of lipoprotein lipase, an enzyme that hydrolyzes triglycerides in chylomicrons and VLDL, providing free fatty acids to the cells. The main sites of apoCII synthesis are represented in the liver and intestine, but apoCII can be also synthesized in the macrophages infiltrated in the atherosclerotic plaque. Patients having apoCII deficiency are unable to clear plasma triglyceride-rich lipoproteins and therefore develop type I hyperlipidemia, characterized by hypertriglyceridemia, xanthomas and increased risk for pancreatitis and atherosclerosis. Studies using transgenic mice have shown that not only apoCII deficiency but also apoCII overexpression induces severe hypertriglyceridemia. Thus, high concentration of apoCII inhibits the activity of lipoprotein lipase, the maturation of HDL particles, and the reverse cholesterol transport and clearance

of lipoproteins by apoE receptors. Therefore, maintaining an optimal level of apoCII expression is essential for the normal metabolism of lipoproteins.

The aim of this thesis is to elucidate the regulatory mechanisms of apoE and apoCII gene expression (apolipoproteins with essential role in lipoprotein metabolism and atherosclerosis) in cell types with key role in the atherosclerotic process.

Modulation of ApoE gene expression. During monocytes differentiation into macrophages, apoE gene expression is induced at transcriptional level by the interaction between promoter and distal regulatory elements, interaction facilitated by binding of several transcriptional factors. The results obtained by 3C technique (chromosome conformational capture) have demonstrated that apoE promoter interacts with the distal regulatory elements ME.2 and ME.1 in monocytes differentiated into macrophages by PMA treatment. Interaction of apoE promoter with multienhancers takes place in the opposite orientation of the two DNA fragments, the sense of orientation being confirmed also by transient transfection experiments.

The multienhancer 2 induced ~ 9-fold the activity of apoE promoter in RAW 264.7 cells, but not in THP-1 monocytes or other cell types tested (HepG2 and HEK293 cells), confirming that the distal regulatory element has a specific action on the apoE promoter in macrophages. The region -100/+73 is the minimum apoE promoter fragment that can be activated by multienhancer 2. The results showed that the whole sequence of ME.2 is necessary for an optimal interaction with the apoE promoter, and for the modulation of apoE promoter activity. In addition the 5'-terminal region of the multienhancer 2 is more important than 3`-terminal region. ME.2 is a transcriptional enhancer that induces the activity of all promoters located in the apoE/apoCI/apoCIV/apoCII gene cluster in macrophages. Studies have shown that ME.2 increases the activity of the four promoters of the gene cluster in the following order apoE>apoCII>apoCIV>apoCI.

The complexity of apoE gene regulation is the result of the interaction of various transcription factors with the proximal and distal regulatory elements, depending on the cell type in which takes place the protein biosynthesis. The role of the transcription factors PU.1, AP-1, STAT1, C/EBP and c-Myb in the modulation of apoE gene expression was tested by transient transfection experiments in two cell types: hepatocytes (the major site of apoE synthesis) and macrophages (peripheral source of apoE, important for its implications in atherogenesis process).

Data showed that PU.1 transcription factors, involved in differentiation of monocytes into macrophages, have a positive role in apoE regulation especially in macrophages, acting indirectly on the apoE promoter through multienhancer 2.

C/EBPα and C/EBPβ transcription factors have an opposite effect in the apoE regulation in macrophages and hepatocytes. Whereas C/EBP overexpression in macrophages decreased the apoE proximal promoter activity, the C/EBP overexpression in hepatocytes resulted in a significant increase in the apoE promoter activity. Interestingly, C/EBPα had a more pronounced effect on apoE promoter activity in hepatocytes, while C/EBPβ had a more pronounced effect in macrophages.

AP-1 transcription factors have opposite effects on the apoE expression in macrophages and hepatocytes. The overexpression of transcription factors c-Jun, c-Fos, Jun B and Jun D in RAW 264.7 macrophages resulted in a decrease of apoE proximal promoter activity and gene expression, whereas overexpression of these factors in HepG2 hepatocytes significantly increased the apoE promoter activity and the amount of mRNA synthesized. The experimental results showed that overexpression of c-Jun decreased the apoE promoter activity even in the presence of SP inhibitor, suggesting that the action of c-Jun on apoE promoter is not dependent on c-Jun phosphorylation.

Experimental results have shown that overexpression of CHOP transcription factors in macrophages and hepatocytes induced a significant decrease in apoE promoter activity, suggesting that under inflammation and stress conditions the amount of apoE synthesized by macrophages will be significantly reduced.

Data showed that c-Myb transcription factors have a positive role in the regulation of apoE expression for c-Myb overexpression induced a significant increase of apoE proximal promoter activity in both RAW 264.7 macrophages and HepG2 hepatocytes. In addition, c-Myb overexpression in HEK cells increased ~ 2 times the apoE gene expression.

Induction of differentiation of monocytes into macrophages by PMA treatment is accompanied by an increased expression of apoE and STAT1. Overexpression of STAT1 transcription factor induces activation of apoE promoter through interaction with ME.2. STAT1 proteins bind to ME.2 and induce indirectly the activation of apoE gene transcription in macrophages (but not in hepatocytes). The STAT1 binding site on multienhancer 2 was identified by multiple experimental pathways: transient transfection, precipitation of proteins bound on biotinylated DNA and chromatin immunoprecipitation.

Modulation of ApoCII gene expression. The results presented in this paper demonstrated that multienhancer 2 interacts with apoCII gene promoter in macrophages. This interaction facilitates transcriptional activation of apoCII promoter through STAT1 transcription factors. We identified a new STAT1 binding site in the region -500/-493 of apoCII promoter, responsible for apoCII activation by STAT1 through transient transfection experiments, the precipitation of proteins bound on biotinylated DNA, and chromatin immunoprecipitation. Interestingly, STAT1 did not exert the stimulatory effect on apoCII promoter when its sequence contained a mutation in RXRα/T3Rβ binding site, suggesting that STAT1 activates the apoCII promoter through interaction with RXRα. For the first time we identified the physical interaction of STAT1 and RXRα transcription factors using the techniques of precipitation of recombinant proteins fused with GST and co-immunoprecipition. Transactivation of apoCII promoter by STAT1 is amplified by RXR ligand in macrophages, indicating that STAT1 and RXRα are important activators of apoCII expression.

Given the essential role of apoE and apoCII in the lipoprotein metabolism, these apolipoproteins are considered important target molecules in the treatment of atherosclerosis. However, the data indicates that apoE or apoCII systemic overexpression in transgenic mice resulted in hypertriglyceridemia. Therefore, the development of strategies to increase the expression of these proteins in certain cell types with key role in atherosclerotic process is imperative.in order to prevent or reduce atherosclerosis. The results presented in this paper demonstrate the specificity of interactions between proximal and distal regulatory elements of apoE or apoCII genes. Through binding of certain transcriptional factors to the distal regulatory elements, the gene expression of these apolipoproteins can be modulated specifically depending on the cell type.

The results of this thesis will contribute to a better understanding of the regulatory mechanisms of apoE and apoCII gene expression, that could lead to the discovery of new strategies in the treatment or prevention of atherosclerosis by increasing the expression of apolipoproteins with beneficial effects or by inhibiting the activity of molecules that decrease the expression of these apolipoproteins.

L'athérosclérose est une maladie inflammatoire chronique qui affecte les artères élastiques (aorte, carotide, iliaque) et musculaires (coronaires, rénales). Au début du dernier siècle, Nikolai Anitschkow a révélé le rôle du cholestérol plasmatique et des lipoprotéines dans le développement de l'athérosclérose, le rôle des apolipoprotéines dans l'athérogenèse étant démontré après l'apparition des modèles expérimentaux des souris transgéniques marquée.

L'apolipoprotéine E (ApoE) est une glycoprotéine de 35 kDa, synthétisée principalement par le foie mais aussi par d'autres tissus et cellules, y compris les macrophages. ApoE est un composant majeur ou mineur des lipoprotéines et intervient de manière essentielle dans leur métabolisme. La carence de l'apolipoprotéine E dans les modèles animaux et chez les patients diabétiques de type hyperlipoproteinemia III est associée à l'athérosclérose précoce. L'expression faible ou absente de l'apoE dans les macrophages, conduit à un processus athérogène, mais les souris transgéniques exprimant l'apoE seulement dans les macrophages ne développent pas d'athérosclérose, même lorsque les niveaux plasmatiques de l'ApoE sont faibles et les animaux sont hypercholestérolémiques. En revanche, les souris transgéniques avec des niveaux de plasma apoE normale, mais sans ApoE exprimé dans les macrophages sont susceptibles de développer une athérosclérose. Le rôle atheroprotecteur de l'apoE est principalement dû au fait que cette protéine est impliquée dans la clearance des lipoprotéines plasmatiques athérogènes (agissant comme un ligand pour plusieurs membres de la famille des récepteurs LDL) et le cholestérol en excès present dans les cellules (en facilitant le transport inverse du cholestérol vers le foie). En outre, l'apoE a de nombreux autres avantages: antioxydant, inhibiteur de l'agrégation plaquettaire, stimulation de la production d'oxyde nitrique, inhibiteur l'activation des lymphocytes T, etc. Etant donné que la modulation de l'expression de l'apoE peut entraîner des effets bénéfiques dans le métabolisme des lipoprotéines, l'apoE est considérée comme une cible thérapeutique importante pour la prévention et le traitement de l'athérosclérose.

L'apolipoprotéine apoCII est une autre protéine plasmatique, associée en particulier avec les chylomicrons et les particules VLDL. L'ApoCII est le principal activateur de la lipoprotéine lipase, une enzyme qui hydrolyse les triglycérides dans les chylomicrons et VLDL. Les principaux sites de synthèse de l'apoCII sont représentés par le foie et l'intestin, mais l'apoCII peut être synthétisé par les macrophages infiltrant la plaque d'athérome. Les patients déficients en ApoCII sont incapables d'éliminer du plasma les lipoprotéines riches en triglycérides et développent une l'hyperlipidémie de type I, caractérisée par

hypertriglycéridémie, xanthomes et un risque élevé de pancréatite et d'athérosclérose. Des études utilisant des souris transgéniques ont montré que non seulement la carence en ApoCII mais aussi la surexpression de l'apoCII induit une hypertriglycéridémie sévère. Ainsi, l'apoCII a concentration elevée inhibe l'activité de la lipoprotéine lipase, la maturation des particules HDL, le transport inverse du cholestérol et l'élimination des lipoprotéines par le biais de récepteurs de l'apoE. Par conséquent, le maintien d'un niveau optimal de l'expression de l''apoCII est essentielle pour le métabolisme normal des lipoprotéines.

L'objectif de cette thèse est de déchiffrer les mécanismes de régulation de l'expression des gènes de l'apoE et de l'apoCII (apolipoprotéines avec rôle dans le métabolisme des lipoprotéines et l'athérosclérose) dans les cellules qui jouent un rôle essentiel dans l'athérosclérose.

Modulation de l'expression de gène ApoE. Au cours de la différenciation des monocytes en macrophages l'expression du gène de l'ApoE est induite au niveau transcriptionnel par l'interaction du promoteur avec les éléments régulateurs distaux, interaction facilitée par la liaison de certains facteurs de transcription. Les résultats obtenus par la technique de 3C (chromosome conformation capture) ont démontré que, dans les monocytes qui se sont différencié en macrophages par un traitement avec de la PMA, le promoteur de l'apoE interagit avec les éléments de régulation distaux ME.1 et ME.2. L'interaction du promoteur avec la séquence d'enhancer se déroule dans l'orientation opposée entre les deux fragments d'ADN l' interaction optimale étant confirmés par des expériences de transfection transitoire.

Multienhancer 2 a induit x9 l'activité du promoteur d'apoE fois dans les cellules RAW 264.7, mais pas dans les monocytes THP-1 et d'autres types cellulaires testés (cellules HepG2 et HEK293), confirmant ainsi que l'élément régulateur distal a une activité spécifique du promoteur de l'apoE dans les macrophages. Le fragment minimum du promoteur de l'apoE qui peut être activée par multienhancer 2 est la région -100/+73. Les résultats ont montré que la séquence entière de ME.2 est nécessaire pour une interaction optimale avec du promoteur l'apoE et pour moduler l'activité du promoteur de l'apoE, la région 5'-terminale de multienhancer 2 est plus importante que la région 3`-terminale. ME.2 est un activateur de la transcription induisant l'activité de tous les promoteurs du groupe de gènes apoE/apoCI/ apoCI`/apoCIV/apoCII dans les macrophages. Nos résultats ont montré que ME.2 augmente l'activité des quatre promoteurs du cluster dans l'ordre suivant apoE>apoCII>apoCIV>apoCI.

La complexité de la régulation du gène de l'apoE est le résultat de l'interaction de nombreux facteurs de transcription avec les éléments proximaux et distaux de régulation, en fonction du type de cellule dans laquelle se produit la biosynthèse de la protéine. Le rôle des facteurs de transcription PU.1, AP-1, STAT1, C/EBP et c-Myb dans la modulation de l'expression apoE a été testé par des expériences de transfection transitoire menées dans deux types cellulaires: hépatocytes (le site majeur de synthèse d'apoE) et macrophages (source périphérique d'apoE, très important car il a des implications pour le processus d'athérogenèse).

Les résultats montrent que les facteurs de transcription de la famille PU.1, impliqués dans la différenciation des monocytes en macrophages, ont un rôle positif dans la régulation de l'apoE spécifiquement dans les macrophages, agissant indirectement sur le promoteur de l'apoE par l'intermediare du multienhancer 2. Les facteurs de transcription C/EBPα et C/EBPß ont un effet inverse dans la régulation de l'apoE dans les macrophages et les hépatocytes; alors que la surexpression de C/EBP dans les macrophages induit l'activité du promoteur proximal de l'apoE, la surexpression de C/EBP dans les hépatocytes entraîne une augmentation significative de l'activité du promoteur. Fait intéressant, C/EBPα eu un effet plus prononcé sur l'activité du promoteur dans les hépatocytes, mais C/EBPß eu un effet plus prononcé dans les macrophages.

Les facteurs AP-1 ont des effets opposés sur l'expression de l'apoE dans les macrophages et les hépatocytes. La surexpression de facteurs de transcription c-Jun, c-Fos, Jun B et Jun D dans des macrophages RAW 264.7 a entraîné une diminution de l'activité du promoteur proximal apoE et de l'expression des gènes, alors que la surexpression de ces facteurs dans les hépatocytes HepG2 a augmenté de façon significative l'activité du promoteur et la quantité d'ARNm synthétisé. Les résultats expérimentaux ont montré que la surexpression de c-Jun entraîne une diminution de l'activité du promoteur d'ApoE, même en présence d'un inhibiteur SP, ce qui suggère que l'action de c-Jun sur le promoteur d'apoE n'est pas dépendant de la phosphorylation de c-jun.

Les résultats expérimentaux ont montré que dans les macrophages et dans les hépatocytes, la surexpression des facteurs de transcription CHOP induit une diminution significative de l'activité du promoteur proximal d'apoE, ce qui suggère que dans les conditions de l'inflammation et de stress, la quantité d'apoE synthétisée par les macrophages est réduite. Les résultats ont montré que les facteurs de transcription c-Myb ont un rôle positif dans la régulation de l'expression d'apoE, alors que la surexpression de c-Myb a induit une augmentation significative de l'activité du promoteur proximal apoE dans les

macrophages RAW 264.7 et les hépatocytes HepG2. En outre, la surexpression de c-Myb dans les cellules HEK a augmenté deux fois l'expression du gène d'apoE.

L'induction de la différenciation des monocytes en macrophages par un traitement avec de la PMA est accompagnée par une augmentation de l'expression de l'apoE et STAT1. La surexpression du facteur de transcription STAT1 induit l'activation du promoteur d'apoE grâce à l'interaction avec ME.2. Les protéines STAT1 se lient à la séquence ME.2 et détermine l'indirectement activation de la transcription du gène de l'apoE dans les macrophages (mais pas dans les hépatocytes). Le site de liaison des facteurs de transcription STAT1 sur multienhancer 2 a été identifié par de multiples voies expérimentale: transfection transitoire, précipitation de protéines sur l'ADN biotinylé et immunoprécipitation de la chromatine.

Modulation de l'expression de gène ApoCII. Les résultats présentés dans ce document démontrent que dans les macrophages multienhancer 2 peut interagir avec le promoteur du gène apoCII et cette interaction facilite l'activation transcriptionnelle du promoteur apoCII par les facteurs de transcription STAT1. Par d'expériences de transfection transitoire, la précipitation des protéines sur ADN biotinylé et immunoprécipitation de la chromatine nous avons identifié un nouveau site de liaison de STAT1 sur région -500/-493 du promoteur apoCII, responsable de l'activation induite par STAT1.

STAT1 n'a pas exercité son effet stimulant sur l'activité du promoteur apoCII lorsque sa séquence contient une mutation dans le site de liaison de RXRα/T3R β, ce qui suggère que le STAT1 active l'apoCII promoteur par l'interaction avec RXRα. En utilisant les techniques de précipitation des protéines recombinantes avec GST et co-immunoprecipitation nous avons demontré pour la première fois une interaction physique entre les facteurs de transcription STAT1 et RXRα. La transactivation du promoteur d'apoCII par STAT1 est amplifié par le ligand RXR dans les macrophages, ce qui indique que STAT1 et RXR sont des activateurs importants dans l'expression d'apoCII.

Compte tenu du rôle essentiel de l'apoE et apoCII dans le métabolisme des lipoprotéines, ces apolipoprotéines sont des molécules cibles importantes pour le traitement de l'athérosclérose. Malgré les nombreux effets favorables de ces apolipoprotéines, la surexpression des apoE ou apoCII chez des souris transgéniques ont donné lieu à l'apparition d'une hypertriglycéridémie. Par conséquent, afin de prévenir ou de réduire l'athérosclérose il est nécessaire d'élaborer des stratégies visant à accroître l'expression de ces protéines seulement dans certains types de cellules ayant un rôle clé dans l'athérosclérose. Les résultats présentés dans ce document montrent la spécificité des interactions entre les

éléments distaux et promoteurs du gène de l'apoE et apoCII. En reliant certains facteurs de transcription à des éléments régulateurs distaux, l'expression de ces apolipoprotéines peut être ajustée notamment en fonction du type de cellule. Les résultats de cette étude contribueront à une meilleure compréhension des mécanismes régulant l'expression des gènes de l'apoE et apoCII, ce qui pourrait conduire à la découverte de nouvelles stratégies pour le traitement ou la prévention de l’athérosclérose par l’augmentation de l’expression "bénéfique" des apolipoprotéines ou en inhibant l'activité des molécules qui diminuent l'expression de ces apolipoprotéines.

Ateroscleroza este o boală inflamatorie cronică care afectează arterele elastice (aorta, carotida, iliaca) şi musculare (coronare, renale). Incă de la începutul secolului trecut, Nikolai Anitschkow a dezvăluit rolul colesterolului şi al lipoproteinelor plasmatice în dezvoltarea aterosclerozei, iar după ce a fost posibilă generarea şoarecilor transgenici, a fost evidenţiat şi rolul apolipoproteinelor în aterogeneză.

Apolipoproteina E este o glicoproteină de 35 kDa, sintetizată în special de către ficat, dar şi de alte ţesuturi şi celule, inclusiv macrofage. ApoE reprezintă un component major sau minor al lipoproteinelor şi are o contribuţie esenţială în metabolismul acestora. Deficienţa apoE, atât în cazul modelelor animale cât şi in cazul pacienţilor cu hiperlipoproteinemie de tip III este asociată cu apariţia prematură a aterosclerozei. Expresia apoE scăzută sau absentă la nivelul macrofagelor, conduce la apariţia procesului aterogen, iar şoarecii transgenici care exprimă apoE doar în macrofage nu dezvoltă ateroscleroză, chiar şi atunci când nivelele apoE plasmatice sunt scăzute şi animalele sunt hipercolesterolemice. În contrast, şoarecii transgenici cu nivele apoE plasmatice normale, dar care nu exprimă apoE în macrofage sunt predispuşi la ateroscleroză. Rolul ateroprotector al apoE se datorează în special faptului că participă la îndepărtarea lipoproteinelor plasmatice aterogene (acţionând ca ligand pentru mai mulţi membri ai familiei de receptori LDL) şi a excesului de colesterol din celule (facilitând transportul invers al colesterolului către ficat). În plus, apoE prezintă multe alte efecte benefice: este antioxidant, inhibă agregarea plachetelor, stimulează producerea oxidului nitric, inhibă activarea celulelor T, etc. Întrucât prin modularea expresiei apoE se pot obţine efecte benefice majore în metabolismul lipoproteinelor, apoE este considerată o ţintă terapeutică importantă pentru prevenirea şi tratamentul aterosclerozei.

Apolipoproteina CII este o altă proteină plasmatică asociată în special particulelor de chilomicroni şi VLDL. ApoCII reprezintă principalul activator al lipoprotein lipazei, enzimă care hidrolizează trigliceridele din chilomicroni şi LDL, furnizând celulelor acizi graşi liberi. Principalele situsuri de sinteză ale apoCII sunt reprezentate de către ficat şi intestin, însă apoCII poate fi sintetizată şi de macrofagele înfiltrate în placa aterosclerotică. Pacienţii cu deficienţă pentru apoCII sunt incapabili să îndepărteze din plasmă lipoproteinele bogate în trigliceride şi prin urmare dezvoltă hiperlipidemie de tip I, caracterizată prin hipertrigliceridemie, xantoame şi risc crescut pentru pancreatită şi ateroscleroză. Studiile realizate folosind şoareci transgenici au demonstrat că nu numai deficienţa apoCII ci şi supraexpresia apoCII induce hipertrigliceridemie severă. Astfel, apoCII în concentraţie mare inhibă activitatea lipoprotein lipazei, maturarea particulelor HDL, transportul invers de colesterol precum şi îndepărtarea lipoproteinelor prin intermediul receptorilor apoE. Prin

urmare, menţinerea unui nivel optim al expresiei apoCII este esenţială pentru metabolismul normal al lipoproteinelor.

Lucrarea de faţă a avut ca scop descifrarea mecanismelor de reglare a expresiei genice a apoE şi apoCII (apolipoproteine cu rol esenţial în metabolismul lipoproteinelor şi implicit în ateroscleroză) în tipuri celulare cu rol cheie în procesul aterosclerotic.

Modularea expresiei genice a ApoE. În timpul diferenţierii monocitelor în macrofage, expresia genică a apoE este indusă la nivel transcripţional prin intermediul interacţiei promotorului cu elementele reglatorii distale, interacţie facilitată de legarea anumitor factorilor transcripţionali. Rezultatele obţinute prin tehnica 3C (captura conformaţională cromosomală) au demonstrat că promotorul apoE interacţionează cu elementele reglatorii distale, ME.1 şi ME.2 în monocite diferenţiate în macrofage prin tratament cu PMA. Interacţia promotorului cu secvenţa multienhancerului are loc în orientarea inversă a celor două fragmente ADN, sensul interacţiei optime fiind confirmat şi prin experimentele de transfecţie tranzientă.

Multienhancerul 2 a indus de ~9 ori activitatea promotorului apoE în celulele RAW 264.7, dar nu şi în monocite THP-1 sau alte tipuri celulare testate (celule HepG2 şi HEK293), confirmând faptul că acest element reglator distal are o acţiune specifică asupra promotorului apoE în macrofage. Fragmentul minim al promotorului apoE care poate fi activat de către multienhancerul 2 este reprezentat de regiunea -100/+73. Rezultatele au arătat că întreaga secvenţă a ME.2 este necesară pentru o interacţie optimă cu promotorul apoE, iar pentru modularea activităţii promotorului apoE regiunea 5`-terminală a multienhancerului este mai importantă decât regiunea 3`-terminală. ME.2 este un enhancer transcripţional care induce activitatea tututor promotorilor genelor din clusterul apoE/apoCI/ apoCI`/apoCIV/apoCII în macrofage. Studiile efectuate au arătat că ME.2 creşte activitatea celor patru promotori din cluster în ordinea următoare apoE>apoCII>apoCIV>apoCI.

Complexitatea reglării genice a apoE este rezultatul interacţiunii a numeroşi factori de transcripţie cu elementele reglatorii proximale sau distale, în funcţie de tipul celular în care are loc biosinteza proteinei. Rolul factorilor de transcripţie PU.1, AP-1, STAT1, C/EBP şi c-Myb în modularea expresiei apoE a fost testat prin experimente de transfectie tranzientă realizate în două tipuri celulare esenţiale: hepatocite (situsul major de sinteză a apoE) şi macrofage (sursa periferică de apoE, foarte importantă deoarece are implicaţii în procesul de aterogeneză).

Datele arată că factorii de transcripţie PU.1, implicaţi în diferenţierea monocitelor în macrofage, au rol pozitiv în reglarea apoE mod specific în macrofage, acţionând indirect asupra promotorului apoE prin intermediul multienhancerului 2.

Factorii de transcripţie C/EBPα şi C/EBPβ au un efect opus în reglarea apoE în macrofage şi hepatocite, întrucât supraexpresia C/EBP în macrofage a indus scăderea activităţii promotorului proximal al apoE, iar supraexpresia C/EBP în hepatocite a determinat o creştere semnificativă a activităţii promotorului. În mod interesant, C/EBPα a avut un efect mai pronunţat asupra activităţii promotorului în hepatocite, iar C/EBPβ a avut un efect mai pronunţat în macrofage.

Factorii din complexul AP-1 au efecte opuse asupra expresiei apoE în macrofage şi hepatocite. Supraexpresia factorilor de transcripţie c-Jun, c-Fos, Jun B şi Jun D în macrofage RAW 264.7 a determinat o scădere a activităţii promotorului proximal al apoE şi a expresiei genice, în timp ce supraexpresia acestor factori în hepatocite HepG2 a crescut semnificativ activitatea promotorului şi a cantităţii de mRNA sintetizată. Rezultatele experimentale au arătat că supraexpresia c-Jun determină scăderea activităţii promotorului apoE chiar şi în prezenţa inhibitorului SP, sugerând faptul că acţiunea c-Jun asupra promotorului apoE nu este dependentă de fosforilarea c-Jun.

Rezultatele experimentale au evidenţiat că atât în macrofage cât şi în hepatocite, supraexpresia factorilor de transcripţie CHOP a indus scăderea semnificativă a activităţii promotorului proximal al apoE, ceea ce sugerează că, în condiţii inflamatorii şi de stres, cantitatea de apoE biosintetizată de către macrofage va fi diminuată.

Datele obţinute arată că factorii de transcripţie c-Myb au rol pozitiv în reglarea expresiei apoE, întrucât supraexpresia c-Myb a indus creşterea semnificativă a activităţii promotorului proximal al apoE atât în macrofage RAW 264.7 cât şi în hepatocite HepG2. În plus, supraexpresia c-Myb în celule HEK a crescut de ~două ori expresia genică a apoE.

Inducerea diferenţierii monocitelor în macrofage prin tratament cu PMA este însoţită de creşterea expresiei apoE şi STAT1. Supraexpresia factorului de transcripţie STAT1 induce activarea promotorului apoE prin intermediul interacţiei cu ME.2. Proteinele STAT1 se leagă la ME.2 şi determină indirect activarea transcripţiei genei apoE, în macrofage (dar nu şi în hepatocite). Situsul de legare al factorilor de transcripţie STAT1 la multienhancerul 2 a fost identificat prin multiple căi experimentale: transfectie tranzientă, precipitarea ADN biotinilat cu streptavidină şi imunoprecipitarea cromatinei.

Modularea expresiei genice a ApoCII. Rezultatele prezentate în această teză au demonstrat că în macrofage multienhancerul 2 poate interacţiona cu promotorul genei

apoCII, iar această interacţie facilitează activarea transcripţională a promotorului apoCII prin intermediul factorilor de transcripţie STAT1. Prin experimente de transfecţie tranzientă, precipitarea ADN biotinilat cu streptavidină şi imunoprecipitarea cromatinei a fost identificat un nou situs de legare a STAT1 în regiunea -500/-493 a promotorului apoCII, responsabil de activarea indusă de STAT1.

În mod interesant, STAT1 nu şi-a exercitat efectul activator asupra promotorului apoCII, atunci când secvenţa acestuia a conţinut o mutaţie în situsul de legare a RXRα/T3R β, sugerând că STAT1 activează promotorul apoCII prin intermediul interacţiei cu RXRα. Folosind tehnicile de precipitare a proteinelor recombinante cu GST şi co-immunoprecipitare a fost evidenţiată pentru prima oară interacţia fizică a factorilor de transcripţie STAT1 şi RXRα. Transactivarea promotorului apoCII de către STAT1 este amplificată de către ligandul RXR în macrofage, evidenţiind faptul că STAT1 şi RXRα reprezintă activatori importanţi ai expresiei apoCII.

Având în vedere rolul esenţial al apoE şi apoCII în metabolismul lipoproteinelor, aceste apolipoproteine reprezintă molecule ţintă importante în terapia aterosclerozei. În ciuda multiplelor efecte benefice ale acestor apolipoproteine, supraexpresia sistemică a apoE sau apoCII la şoarecii transgenici a determinat apariţia hipertrigliceridemiei. Prin urmare, în scopul prevenirii sau reducerii aterosclerozei este nevoie de elaborarea unor strategii de creştere a expresiei acestor proteine doar în anumite tipuri celulare cu rol cheie în procesul aterosclerotic. Rezultatele prezentate în această lucrare demostrează specificitatea interacţiilor dintre elementele reglatorii distale şi promotorii genelor apoE şi apoCII. Prin legarea anumitor factori transcripţionali la elementele reglatorii distale, expresia genică a acestor apolipoproteine poate fi reglată în mod specific în funcţie de tipul celular.

Rezultatele acestui studiu vor contribui la o mai bună înţelegere a mecanismelor de reglare a expresiei genice a apoE şi apoCII, ceea ce ar putea duce la descoperirea unor noi strategii de tratament sau prevenire a aterosclerozei prin creşterea expresiei apolipoproteinelor cu efecte benefice sau prin inhibarea activităţii moleculelor care scad expresia acestor apolipoproteine.

INTRODUCERE 11
LISTĂ ABREVIERI 14
I. STADIUL ACTUAL AL CUNOAȘTERII 17
I.1 Boala valvei aortice 17
I.1.1 Biologia și ontogeneza valvei aortice 17
I.1.1.1 Organizarea valvei aortice 17
I.1.1.2. Ontogeneza valvei aortice 18
I.1.1.3 Structura valvei aortice 18
a. Celule endoteliale valvulare (VEC) 18
b. Celule interstițiale valvulare (VIC) 19
c. Alte tipuri celulare 20
I.1.2 Calcificarea valvei aortice (CVA) 20
I.1.2.1. Epidemiologia calcificării valvei aortice 20
I.1.2.2. Factori de risc ai calcificării valvei aortice 21
I.1.2.3. Mecanismele celulare și moleculare ale calcificării valvei 22
a. Activarea celulelor endoteliale 23
b. Diferențierea celulelor interstițiale valvulare native (quaiescent, qVIC) în miofibroblaste 24
c. Osteodiferențierea celulelor valvulare interstițiale 25
d. Remodelarea matricei extracelulare 31
e. Formarea nodulilor de calcificare 32
I.1.2.4. Calcificarea valvei aortice (CVA) și ateroscleroza 33
I.1.2.5. Calcificarea valvei aortice în diabet 34
I.2 Abordări terapeutice în calcificarea valvei aortice 36
I.2.1 Înlocuirea chirurgicală a valvei aortice 36
I.2.2 Inhibitori ai moleculelor și căilor de semnalizare implicate în calcificarea valvei aortice 37
I.2.3 Statine 38
I.2.4 Alte tratamente 38
I.3 Folosirea nanoparticulelor în tratamentul bolilor cardiovasculare 39
I.3.1 Tipuri de nanoparticule 39
a. Nanoparticule pe bază de carbon 40
b. Dendrimeri 41
c. Nanoparticule polimerice 41
d. Nanoparticule lipidice 42

I.3.2 Modalități de transport (pasiv/activ) ale nanoparticulelor....44
I.3.2.1 Transportul pasiv al nanoparticulelor....45
I.3.2.2 Transportul activ al nanoparticulelor....46
I.3.3 Molecule utilizabile drept ținte în transportul direcționat al nanoparticulelor la valva aortică afectată....46
I.3.3.1 Molecule de adeziune celulară....47
a. Selectine....47
b. Integrine....49
c. Molecule de adeziune celulară din superfamilia imunoglobulinelor....49
I.3.3.2 Colagen tip IV....51
I.3.4 ARN de interferență....52
I.3.5 Folosirea ARN-ului de interferență în tratamentul bolilor cardiovasculare....55
I.4 Concluzii....57
II. CONTRIBUȚII ORIGINALE....59
STRATEGII NANOTERAPEUTICE PENTRU BLOCAREA PROCESULUI DE OSTEODIFERENȚIERE AL CELULELOR VALVULARE INTERSTIȚIALE (VIC)....60
II.1. Osteodiferențierea VIC indusă de concentrații crescute de glucoză și factori osteogeni - Rolul factorului de transcriere Runx2 în osteodiferențierea VIC....60

Introducere și obiective

Calcificarea valvei aortice este o boală degenerativă care afectează 5% din populația de peste 65 ani, România fiind una dintre țările cu cea mai mare rată de mortalitate din Europa (http://www.romedic.ro/stenoza-aortica). Diagnosticarea timpurie și gestionarea tratamentului sunt de o importanță capitală în terapia bolii valvei aortice, întrucât nu există un tratament care să blocheze progresia acesteia. În cazul pacienților cu simptome grave, intervenția chirurgicală de înlocuire de valvă rămâne singura abordare (Kanwar et al., 2018; Iung et al., 2003), prognosticul sever al bolii nefiind influențat de medicația actuală folosită pentru tratarea simptomelor. Progresia calcificării valvei și necesitatea unei intervenții chirurgicale variază considerabil de la pacient la pacient, în majoritatea cazurilor obstrucția totală înregistrându-se în decurs de 2-5 ani de la instalarea calcificării (Owens et al., 2010).

Valva aortică este alcătuită din trei straturi de celule valvulare interstițiale (VIC) cu rol în menținerea homeostaziei valvei, separate de cavități printr-un strat de celule valvulare endoteliale (VEC) (Rutkovskiy et al., 2017). Principalul proces implicat în calcificarea valvei aortice este diferențierea osteoblastică a VIC sub influența factorului de transcriere asociat Runt 2 (Runx2)/Factorul de legare la nucleu 1 (Cbfa1). Runx2 determină creșterea expresiei unor molecule specifice VIC osteodiferențiate: fosfatază alcalină, osteocalcină, osteopontină, sialoproteină osoasă, și contribuie la depunerea activă de calciu (Hortells et al., 2018).

Deși alterarea metabolismului lipidelor și inflamația sunt implicate în inițierea calcificării valvei aortice, procesul activ de depunere a calciului este cel mai important în

progresia bolii (Pawade et al., 2015). Diabetul zaharat este un factor de risc și de predicție al degenerării valvei aortice, contribuind la progresia calcificării prin inducerea disfuncției celulelor endoteliale valvulare, remodelarea matricei extracelulare, instalarea inflamației și calcificarea ectopică (depunerea calciului în alte țesuturi decât cel osos) (Larrew et al., 2013).

La momentul actual nu se cunosc ținte particulare sau terapii specifice pentru tratamentul bolii valvei aortice în asociere cu diabetul zaharat. Fiind o arie de interes cu evoluție rapidă, nanoterapia bolii valvei aortice are implicații pe plan medical, dar și socio-economic, efectele acesteia fiind îmbunătățirea condiției de viață, creșterea speranței de viață și scăderea morbidității și mortalității.

Scopul prezentei teze de doctorat a fost de a identifica mecanismele și moleculele implicate în osteodiferențierea celulelor valvulare interstițiale, proces principal în calcificarea valvei aortice în asociere cu diabetul zaharat, și dezvoltarea și aplicarea unor strategii nanoterapeutice țintite pentru blocarea acestui proces în vederea reducerii sau combaterii timpurii a calcificării valvei aortice.

Au fost propuse și realizate următoarele **obiective specifice**:

1. Studiul mecanismelor implicate în osteodiferențierea celulelor valvulare interstițiale (VIC) și identificarea de potențiale ținte terapeutice. În cadrul acestui obiectiv s-au descris modificările timpurii și avansate induse, *in vitro*, de concentrații crescute de glucoză și factori osteogeni în VIC.
2. Conceperea, obținerea și caracterizarea unor nanoparticule țintite pentru blocarea osteodiferențierii VIC și validarea efectului terapeutic al acestor nanoterapii folosind modele experimentale *in vitro*. S-au obținut și caracterizat poliplexe formate din fulerena C60-PEI complexată cu plasmide ARNsh și lipopoliplexe direcționate specific, formate prin încapsularea poliplexelor menționate în liposomi. Efectul terapeutic al nanoparticulelor a fost stabilit pe sisteme de culturi celulare bi- și tridimensionale de VIC osteodiferențiate cultivate în mediu cu o concentrație crescută de glucoză și factori osteogeni.
3. Validarea preclinică a nanoterapiilor dezvoltate folosind modelul experimental *in vivo* de șoarece ApoE-deficient hiperlipemic și diabetic. În cadrul acestui studiu s-a demonstrat acumularea lipopoliplexelor țintite obținute și caracterizate anterior *in vitro* în valva disfuncțională și efectul terapeutic al acestor nanoparticule în valva aortică a șoarecilor ApoE-deficienți hiperlipemici și diabetici.

Structura tezei de doctorat

Prezenta teză de doctorat este structurată în două părți principale, divizate în opt capitole.

Prima parte, alcătuită din trei capitole, cuprinde aspecte teoretice cu privire la biologia și patologia valvei aortice, dar și la principalele terapii abordate în boala valvei aortice. **Capitolul 1** descrie anatomia, fiziologia și ontogeneza valvei aortice, cu accent asupra principalelor mecanisme celulare și moleculare implicate în calcificarea valvei aortice în diabet. **Capitolul 2** prezintă pe scurt stadiul actual al abordărilor terapeutice în calcificarea valvei aortice, urmând ca în **Capitolul 3** să se detalieze diferitele tipuri de nanoparticule transportoare de ARN de interferență sau medicamente folosite ca tratament în bolile cardiovasculare, principalele căi de transport ale acestora la valva aortică și mecanismul de acțiune al ARN-ului de interferență în terapia valvei aortice calcificate. De asemenea, în acest capitol se face referire și la moleculele supraexprimate de valva aortică afectată, ce pot fi folosite în direcționarea nanoparticulelor (colagen IV, molecule de adeziune a celulelor vasculare).

Partea a doua a lucrării cuprinde contribuțiile originale, structurate în cinci capitole. În **primul capitol** este descris protocolul de osteodiferențiere al VIC aortice umane (oVIC) *in vitro* folosind mediu de cultură HGMO ce conține concentrații crescute de glucoză și factori osteogeni (acid ascorbic, dexametazonă și β-glicerofosfat), aplicabil atât în cultură bidimensională (2D), cât și tridimensională (3D). În fazele timpurii ale calcificării valvei aortice, după denudarea stratului de VEC, lipidele și celulele imune ajung în stratul subendotelial. Citokinele eliberate de celulele imune inițiază procesul inflamator, determinând remodelarea matricei extracelulare și tranziția fenotipică a VIC la miofibroblaste (aVIC), caracterizate prin supraexpresia actinei α a mușchiului neted și prezența fibrelor de stres. În stadiile avansate, ca răspuns la stimularea pro-osteogenică (inflamație, stres mecanic), are loc osteodiferențierea VIC, principalul proces implicat în calcificarea ectopică a foițelor valvulare. Se cunoaște că diabetul este unul dintre factorii acceleratori ai depunerii active de calciu în valva aortică (Bossé et al., 2009).

Principalele rezultate obținute:

- Mediul HGMO ce conține o concentrație crescută de glucoză și factori osteogeni induce osteodiferențierea VIC (oVIC) prin supraexprimarea moleculelor osteogene (fosfatază alcalină, osteopontină, sialoproteină osoasă, proteină morfogenică osoasă) și
- Creșterea anormală a activității enzimatice a fosfatazei alcaline și acumularea de calciu în oVIC.

Rezultatele acestui studiu au fost publicate în revista Pharmaceutics (factor de impact 6.321) (Voicu et al., 2020).

În **Capitolul 2** al tezei de doctorat este prezentat protocolul de formare al poliplexelor prin complexarea conjugatului fulerenă C60-polietilenimină (C60-PEI) cu plasmide ce conțin secvențe specifice short hairpin ARN (ARNsh) pentru factorul de transcriere Runx2 implicat în osteodiferențierea VIC, caracterizarea și efectul terapeutic indus de silențierea Runx2 în oVIC prin intermediul acestor poliplexe.

Principalele rezultate obținute:

- Conform caracterizării fizico-chimice, poliplexele au dimensiuni de ~ 250 nm la rapoarte N/P mai mari de 25, iar potențialul Zeta crește dependent de raportul N/P, fiind de +15 mV la raportul N/P=25.
- Poliplexele sunt citocompatibile cu VIC umane la toate rapoartele N/P investigate (10, 15, 20, 25).
- Poliplexele sunt preluate eficient de către VIC, fapt dovedit de prezența intracelulară a punctelor roșii reprezentând plasmidul fluorescent Cy3.
- Poliplexele au o capacitate de transfecție ridicată la raportul N/P=25.
- Testele funcționale au arătat că poliplexele ce conțin secvențele plasmidiale ARNsh numerotate cu sh_1 și sh_2 (C60-PEI/sh_1, C60-PEI/sh_2) reduc exprimarea proteică a factorului de transcriere Runx2, dar și a altor proteine implicate în activarea și osteodiferențierea VIC (αSMA, Smad2/3, pSmad2/3, fosfatază alcalină, osteopontină, sialoproteină osoasă, proteină morfogenică osoasă 4).
- Poliplexele C60-PEI/sh_1, C60-PEI/sh_2 scad activitatea fosfatazei alcaline după o singură sau o dublă transfecție a oVIC. Activitatea scăzută a fosfatazei alcaline se menține mai mult de o săptămână de la ultima transfecție (până la 21 zile).

Rezultatele acestui studiu au fost publicate în revista Pharmaceutics (factor de impact 6.321) (Voicu et al., 2020).

Capitolul 3 prezintă protocolul de obținere al lipopoliplexelor ce presupune încapsularea poliplexelor preformate C60-PEI/sh_1 la raportul N/P=25 în liposomi anionici stabilizați cu

polietilenglicol și direcționarea lor specifică către molecule supraexprimate de oVIC: colagenul IV și molecula de adeziune a celulelor vasculare VCAM-1. De asemenea, aceste nanoparticule sunt caracterizate și prin evaluarea potențialului lor de a bloca diferențierea osteoblastică a VIC cultivate în sistem 2D și 3D.

În ciuda eficienței ridicate de transfecție *in vitro*, utilizarea poliplexelor *in vivo* nu a avut efecte terapeutice semnificative, din cauza sarcinilor pozitive ce determină interacțiunea nespecifică cu proteine plasmatice și acumularea acestor poliplexe în ficat și splină (Fischer et al., 2004). Pentru creșterea stabilității poliplexelor în circulația sangvină și pentru a îmbunătăți rata de transfecție, scăzând în același timp toxicitatea, acestea pot fi încapsulate în liposomi stabilizați steric cu polietilenglicol (Ko și Bickel, 2012), ceea ce permite și funcționalizarea liposomilor în vederea unui transport direcționat către situsul afectat (Călin și Mânduțeanu, 2017).

Principalele rezultate obținute:

- oVIC prezintă o supraexpresie a colagenului IV și VCAM-1, molecule ce pot fi folosite pentru direcționarea lipopoliplexelor.
- S-au obținut lipopoliplexe prin încapsularea poliplexelor C60-PEI/sh_1 în liposomi anionici, folosind tehnica de evaporare în fază inversă.
- Caracterizarea fizico-chimică a indicat dimensiuni medii ale lipopoliplexelor de ~ 200 nm și un potențialul Zeta negativ, de -30 mV, acestea fiind dispersii apoase stabile coloidal și electrolitic.
- Lipopoliplexele ColIV-LPP/shControl și V-LPP/shControl sunt cito- și hemocompatibile și sunt preluate într-o proporție crescută de oVIC.
- Lipopoliplexele ColIV-LPP/shRunx2 și V-LPP/shRunx2 determină reducerea semnificativă a nivelului genic și proteic al Runx2 în oVIC, atât în sistem 2D, cât și 3D, ceea ce are ca efect și reducerea nivelelor altor molecule osteogene implicate în osteodiferențierea VIC (osteopontină, sialoproteină osoasă, proteină morfogenică osoasă 2).
- Testele funcționale au arătat că transfecția oVIC cu ColIV-LPP/shRunx2 și V-LPP/shRunx2 scade activitatea fosfatazei alcaline și blochează formarea depozitelor de calciu, printr-un mecanism ce implică scăderea nivelului de Runx2.

Rezultatele acestui studiu au fost publicate în revista International Journal of Molecular Sciences (factor de impact 6.009) (Voicu et al., 2022).

Capitolul 4 cuprinde rezultate obținute *in vivo*, pe un model animal de șoarece ApoE-deficient diabetic și hiperlipemic injectat intravenos cu lipopoliplexe dublu direcționate către colagen IV și VCAM-1 (ColIV/V-LPP/shControl). S-a investigat biodistribuția acestor lipopoliplexe la nivelul organelor murine, și în special la nivelul valvei aortice, lipopoliplexele fiind marcate cu rodamină-DSPE pentru evaluarea localizării lipopoliplexelor în organe *ex vivo* prin tehnica IVIS. Datorită fotostabilității și emisiei în spectrul vizibil, rodamina este folosită cu succes în studiile de imagistică și de microscopie de fluorescență (de Almeida et al., 2007).

Principalele rezultate obținute:

- Valvele aortice ale șoarecilor ApoE-deficienți diabetici și hiperlipemici prezintă o expresie crescută de colagen IV și VCAM-1.
- Lipopoliplexele ColIV/V-LPP/shControl se localizează specific la nivelul valvei aortice, biodistribuția fiind corelată cu prezența expresiei ridicate de colagen IV și VCAM-1 în valvă.
- Expresia fluorescentă a proteinei YFP la nivelul valvelor aortice se menține până la 48 ore de la injectarea ColIV/V-LPP/pEYFP.

Rezultatele prezentate în **Capitolul 5** demonstrează efectul terapeutic al lipopoliplexelor dublu direcționate transportoare de secvențe ARNsh-Runx2 într-un model animal de șoarece ApoE-deficient diabetic și hiperlipemic.

Principalele rezultate obținute:

- Lipopoliplexele ColIV/V-LPP/shRunx2 scad expresia genică și proteică a Runx2 în valva aortică, determinând și reducerea expresiei genice a osteopontinei, osteocalcinei și fosfatazei alcaline. ColIV/V-LPP/shRunx2 determină scăderea nivelului genic de Runx2 și în alte organe (plămân, rinichi, ficat), dar fără semnificație statistică.
- Reducerea nivelului de Runx2 blochează depunerea lipidelor și scade activitatea fosfatazei alcaline în valva aortică.

Rezultatele obținute în cadrul tezei de față au condus la următoarele **concluzii cu caracter original**:

- Concentrațiile crescute de glucoză și factorii osteogeni (acid ascorbic, dexametazonă, β-glicerofosfat) determină o creștere dependentă de timp a exprimării proteice a moleculelor osteogene implicate în activarea (actina α a mușchiului neted) și osteodiferențierea celulelor valvulare interstițiale (VIC) (Runx2, fosfatază alcalină, sialoproteină osoasă, osteopontină). Creșterea nivelului proteic al moleculelor osteogene se asociază cu activitatea ridicată a fosfatazei alcaline și creșterea concentrației de calciu în VIC osteodiferențiate, creșterea fiind direct proporțională cu perioada de expunere la factori osteogeni.
- Nanopoliplexele formate prin complexarea fulerenei (C60)-PEI cu plasmide ARNsh-Runx2 sunt citocompatibile și realizează un transport intracelular eficient de plasmide ARNsh, determinând scăderea nivelului proteic al moleculelor osteogene Runx2, actina α a mușchiului neted, Smad2/3, fosfatază alcalină, sialoproteină osoasă, osteopontină, proteină morfogenică osoasă 4, precum și reducerea activității fosfatazei alcaline.
- Lipopoliplexele formate prin încapsularea poliplexelor C60-PEI/ARNsh-Runx2 în liposomi funcționalizați cu peptide ce recunosc specific colagenul IV și VCAM-1 (ColIV-LPP/ARNsh-Runx2 și V-LPP/ARNsh-Runx2), molecule supraexprimate în valva aortică disfuncțională, sunt nanotransportori adecvați pentru transportul direcționat de plasmide ARNsh-Runx2 *in vivo*. Aceste lipopoliplexe țintite determină scăderea semnificativă a expresiei genice și proteice a moleculelor osteogene în VIC osteodiferențiate cultivate în două sisteme de cultură, bidimensional în monostrat și tridimensional în construcți de tip hidrogel obținut din rădăcină aortică porcină. De asemenea, activitatea fosfatazei alcaline și concentrația de calciu scad semnificativ după transfecția cu lipopoliplexele ColIV-LPP/ARNsh-Runx2 și V-LPP/ARNsh-Runx2.
- *In vivo*, într-un model animal de șoarece ApoE-deficient hiperlipemic diabetic, lipopoliplexele dublu direcționate către colagen IV și VCAM-1 se acumulează selectiv la nivelul valvei aortice disfuncționale. Administrările repetate de lipopoliplexe reduc leziunile aterosclerotice prin scăderea expresiei factorilor osteogeni Runx2, osteopontină, osteocalcină, fosfatază alcalină implicați în calcificarea valvei aortice.

Această teză de doctorat aduce următoarele **contribuţii originale**:

► Stabilirea unui model *in vitro* de osteodiferențiere a celulelor valvulare interstițiale.

► Silențierea factorului de transcriere Runx2 poate reprezenta o strategie nouă terapeutică, eficientă în blocarea osteodiferențierii VIC și a progresiei bolii valvei aortice.
► Dezvoltarea de nanocărăuși de ARNsh specific pentru Runx2, țintiți către valva aortică afectată și adecvați pentru administarea *in vivo*. Acești nanocărăuși sunt lipopoliplexe, și anume liposomi ce încapsulează poliplexe C60-PEI/ARNsh-Runx2, funcționalizați cu peptide de recunoaștere a colagenului IV și a moleculei de adeziune a celulelor vasculare 1 (VCAM-1). Lipopoliplexele blochează diferențierea osteoblastică a celulelor valvulare interstițiale *in vitro* și calcificarea valvei aortice *in vivo,* prin reducerea nivelului factorului de transcriere Runx2 și a altor proteine osteogene (osteopontină, sialoproteină osoasă, fosfatază alcalină, osteocalcină și proteina morfogenică osoasă).

VALORIFICAREA REZULTATELOR

Rezultatele obținute în perioada programului doctoral din cadrul Institutului de Biologie și Patologie Celulară „Nicolae Simionescu" al Academiei Române au fost valorificate astfel:

- publicate în **7 lucrări în reviste indexate ISI**: **2 ca prim-autor** și **5 în calitate de co-autor**
- prezentate în cadrul **conferințelor internaționale** sub forma **unei prezentări orale** și a **3 postere**
- incluse într-**o aplicație de brevet la OSIM.**

Unul dintre articolele publicate în calitate de prim-autor a fost selectat pentru a ilustra coperta revistei „International Journal of Molecular Sciences" în numărul din aprilie 2022, "VCAM-1 targeted nanocarriers of shRNA-Runx2 for calcific valve disease treatment". Rezultatele cercetării au fost premiate de UEFISCDI prin acordarea a 4 premii.

LUCRĂRI PUBLICATE ÎN REVISTE INTERNAȚIONALE COTATE ISI (7 lucrări)

Prim-autor (2):

BURSA OBȚINUTĂ PE DURATA PROGRAMULUI DOCTORAL

Bursă de doctorat: Academia Română (SCOSAAR): 2017-2020

FINANȚAREA CERCETĂRILOR (GRANTURI):

1. **PN-II-RU-TE-2014-4-1837**

Proiect de cercetare pentru stimularea constituirii de tinere echipe de cercetare independente

Titlul proiectului: Nanoterapii țintite către endoteliu, proiectate pentru silențierea receptorului pentru produșii de glicare avansată (RAGE) în ateroscleroză (NANORAGE)

Perioada: 2015-2017

Director de proiect: Dr. Manuela Călin

2. **POC ID P_37_298; 115/13.09.2016**

Programul Operaţional Competitivitate, Axa prioritară 1: Cercetare, dezvoltare tehnologică şi inovare (CDI) în sprijinul competitivităţii economice şi dezvoltării afacerilor

Titlul proiectului: Terapii țintite pentru boala valvei aortice în diabet (THERAVALDIS)

Perioada: 2016 - 2020

Director de proiect: Dr. Agneta Simionescu

3. **13PCCDI/2018**

Proiecte complexe realizate în consorţii Cercetare Dezvoltare Inovare

Titlul proiectului: Terapii inteligente pentru boli non-comunicabile, bazate pe eliberarea controlată de compuși farmacologici din celule încapsulate după manipulare genetică sau bionanoparticule vectorizate (INTERA)

Perioada: 2018-2020

Director de proiect: Acad. Maya Simionescu

4. **PN-III-P4-ID-PCCF-2016-0050**

Proiecte complexe de cercetare de frontieră

Titlul proiectului: Mimarea mecanismelor viului prin abordări ale chimiei supramoleculare, în cinci dimensiuni

Perioada: 2018-2022

Director de proiect: Dr. Aatto Laaksonen

5. **PN-II-P4-ID-PCE-2020-2465**

Proiecte de cercetare exploratorie

Titlul proiectului: Terapie direcționată bazată pe nanocarrieri biomimetici pentru rezoluția inflamației în ateroscleroză (NANORES)

Perioada: 2021-2023

Director de proiect: Dr. Manuela Călin.
